Tractor Trial Wanted

THE automobile arrived at its present stage of development as rapidly as it did largely because of the practice of organizing trials to destruction. Something much the same is now needed if the pace of progress in tractor engineering is to be accelerated to a maximum.

The best way to test a machine is to pit it against the hardest possible task and to increase the severity of the conditions till something breaks. Thus step by step the weak spots are found and can be eliminated. A thousand miles' trial 10 years ago showed more about the weak spots in automobile chassis than would have been discovered in 2 years of normal service.

A properly arranged tractor trial or series of trials held now would settle some of the vexed questions of design outright, questions that will make years to settle if service in the user's hands is to be the only criterion.

The three main needs of a tractor are:

1—Power sufficient to meet all conditions.

2—Efficiency to prevent waste of power.

3—Reliability to prevent delays and expense.

Tractor engineers are not yet satisfied on any of these counts. The proper power is not known, or is not agreed upon. The efficiency of the transmission, the fuel efficiency and the oil efficiencies are admittedly capable of improvement. The most frequent causes of trouble, defeating reliability, are only known machine by machine and not generally.

A competitive trial is the best way to answer the multitudes of questions into which these three main heads can be divided. Not a competitive trial arranged for advertising purposes, a trial intended to show how fine and grand everything is, but a trial to the breakdown point, a trial so drawn that weakness cannot fail to be discovered.

Just to indicate roughly the sort of lines along which a tractor test ought to be arranged, mention may be made of a few of the main things that should be included.

First, make a horsepower test at the flywheel and a drawbar horsepower test, both at full power.

Second, have a long field trial, say 12 hours' plowing at full load.

Third, repeat the flywheel and drawbar power tests to see if there is any falling off in power or efficiency.

Fourth, throughout the fuel and oil consumed should be measured and the number of stops and the reasons for them noted.

Fifth, the time taken in cleaning and oiling vital parts should be observed competitively.

Sixth, ease of control should be a factor in the awards.

Seventh, something should be devised that would show up the advantages of accessibility and of proper inclosure of working parts.

Eighth, protection against weather should be tested in some way and the facilities for replacing such parts as are bound to wear out. For example, where a ring gear is used on the driving wheel, part of the test should be the removal and replacement of the pinions on the driveshafts, against the watch.

At the present stage there should be no need to classify machines. It is just a matter of work done against cost of doing that work; of work done against wear and tear in the doing of it. One trial of a day's duration is, of course, not sufficient or anything like sufficient; a series is needed testing first one sort of service and then another. For example, we have dry weather good for plowing and wet weather good for a hauling test on the road. Everything that the tractor can legitimately be asked to do wants to be done competitively and in a big way.

Mathematical Cycles

IT has now been convincingly proved—by mathematics—that the constant pressure cycle is and is not the answer to many of the constant volume problems. The formulæ of thermo-dynamics have been called upon to advantage by both sides in the argument, and it seems now that the only remaining thing to do is for some of the firm believers in the future of the constant-pressure cycle to step forth with a manufactured engine and let all interested parties see it perform its work efficiently or inefficiently, as the case may be. Mathematical arguments and even blueprints of suggested engines will never tell the story.

Rio Brazil's Business Center

U. S. A. Car and Accessory Makers Should Establish Headquarters in That City

WASHINGTON, D. C., Aug. 28—"If you are contemplating establishing your car or accessory business in Brazil you should establish such headquarters in the city of Rio de Janeiro." This advice is contained in a recent consular letter from the consul-general at Rio. "While Rio may to-day not be so good a market for U. S. A. cars or accessories as the city of Sao Paulo, and while Rio is situated in a federal district surrounded by mountains so that you cannot tour 50 miles to the summer capital, yet Rio is the correct place for Brazilian headquarters of any U. S. A. firm. The reason is simple.

"Brazil is an assemblage of twenty-one states, each of which has a remarkable degree of autonomy, and the capital city of Rio is located in a federal district, just like Washington in the District of Columbia. Articles Nos. 7 and 9 of the Brazilian constitution provide that the Federal Government enjoys the duties from customs and other duties on all imports.

"The duties which may be levied and collected on all exports are the properties of the individual states in which the factories are located, and each of the twenty-one states has its own export tax and can change these taxes to suit its pleasure.

No Export Duty

"It is this export tax situation that makes it infinitely more important for a foreign corporation or manufacturer to establish headquarters in Rio as compared with Sao Paulo or any other Brazilian city. Rio levies no export duty on parts shipped to any of the Brazilian states or to any foreign countries. Thus by establishing headquarters in Rio you can ship to any and all of the twenty-one Brazilian states without fear of an export tax, and you can ship to any of the other South American countries if desired.

"There is a further advantage in establishing headquarters in Rio. The city of Rio de Janeiro occupies practically a monopoly in the distribution of merchandise throughout Brazil. This distribution is chiefly by means of the government-owned railways, the Central Railway of Brazil, which connects the federal capital with the interior, and also by the many coastwise steamers of the Lloyd-Brasileiro Steamship Co., also a government-owned system. This company also has a line of ships running between the U. S. A. and Brazil.

"Further, the importance of Rio as a distributing center for Brazil is shown by the fact that thousands of merchants from the different states visit Rio annually. Rio is the political as well as the mercantile center of the country.

"The American salesman who comes here with a motor car whose merits he is prepared to demonstrate asks, first of all, for an operating license. He is naturally inclined to think that this is due him as a right. Unfortunately, the local law makes no provision for temporary operating licenses, and what he considers as no more than his due must be asked for, as a 'special privilege to a foreign firm,' by the consulate-general. Brazil does not have two forms of licenses, one for the owner or demonstrator of a car and another for the professional chauffeur; nor is an applicant immediately granted an operator's license without examination.

"Once he has obtained a special license the salesman must be prepared to show it on all occasions, and perhaps to submit to a little curious inquiry of a purely personal nature on the part of some good-natured policeman with a thirst for knowledge as to the enterprising methods of foreign firms. The license is not based upon the horsepower of the car, and it is not valid after one has crossed a state boundary. It is to be hoped that within a short time certain ordinances may be passed in Brazil which may alleviate most of the difficulties now encountered in that country.

"There is no class of salesmen who should more carefully remember the requirement of the Brazilian customs laws regarding samples than automobile salesmen. A salesman who has with him cars for demonstrating purposes should remember that he cannot have them enter the country in bond without, before his departure from the United States, obtaining a Brazilian consular invoice declaring them to be samples."

1000 Per Cent Increase in Springfield Body Orders

SPRINGFIELD, MASS., Aug. 26—A 1000 per cent increase in orders during the last 12 months has been made by the Springfield Body Co., this city. Those companies which have adopted the Springfield body as standard equipment include: Abbott-Detroit; Cadillac; Cole; Davis; Haynes; Interstate; Marmon; Mitchell; Oldsmobile; Overland; Paige-Detroit; H. A. L.; Reo; Stearns; Studebaker; Velie; Westcott and Winton.

—

Peerless to Build Addition

CLEVELAND, OHIO, Aug. 26—The Peerless Motor & Truck Co. will build an addition to take care of the European order for trucks recently received.

Bearings Service Co. Organized

Will Take Over Timken, Hyatt and New Departure Service Work

DETROIT, MICH., Aug. 26—The Bearings Service Co. has been organized here to handle the service for anti-friction bearings for all types of motor vehicles, and already has contracted with Timken, Hyatt and New Departure to conduct the service operations for these three large bearing manufacturers. The Bearings Service Co. in reality takes over the service operations of these three, and the idea is similar to that of the union railway station, where competing lines enter a city. Instead of a station for each railway, one station takes care of all.

It is pointed out that the Bearings Service Co. is entirely separate from the companies whose product it will care for, and it is interesting to note that the automobile business, which means progress, has taken the initiative in this new industrial move—a union of competitors so that their service to the public may be more far-reaching and effective.

Branches with Complete Stocks

The Hyatt company has service branches in the principal automobile centers, and Timken also has several such branches, but these will all be taken over by the new company, and it is stated that when, in the fore part of September, the Bearings Service Co. begins active operations a union station will be opened in each of nine separate cities. All will carry complete stocks of all of the bearings manufactured by the companies above mentioned.

It is the plan to eventually establish union stations in fifty or more automobile cities, thereby placing this service within reach of most motorists.

The general offices of the new concern are located here. No details as to the men back of the new venture are divulged at this time. It may be said, however, that it is amply financed.

—

Dann to Make Self-Oiling Bearing Material in New Plant

CLEVELAND, OHIO, Aug. 28—The Dann Products Co., Chicago, Ill., maker of the Dann spring insert for lubrication purposes, will build a plant in this city in which it will also make a combination of graphite and metal for bearings which, it is claimed, will not require lubrication. Three acres costing about $17,500 have been bought in East 152nd Street, adjoining the new plant of the Jordan Motor Car Co. The Dann plant will cost upward of $100,000.

Alliance Tire Co. To Expand

Capital Increased from $150,000 to $650,000—200% Larger Output Planned

ALLIANCE, OHIO, Aug. 28—An increase of $500,000 in capital stock from $150,000 and a 200 per cent increase in the output of the Alliance Tire Co. has been voted by its stockholders.

In order to accomplish this, a new company, known as the Alliance Tire & Rubber Co., will be formed, securities in which will be marketed to the general public. The stockholders will take the preferred stock of the new company at par for their present holdings and a 20 per cent stock dividend, payable in common stock of the new company.

The additional capital will be used for the enlargement of the factory, the installation of additional mills, calenders and vulcanizers. A three-story structure closely resembling the original plant, to be built immediately adjoining the present plant, is under consideration.

Cutting, Armstrong & Smith Seek Site for Plant Addition

ROCKFORD, ILL., Aug. 26—Representatives of the Cutting, Armstrong & Smith Products Co., Detroit, Mich. were here this week, looking for a site for a proposed addition to their $3,000,000 automobile engine plant. Other cities of Illinois and the Middle West will be visited before a location is selected. Motors and axles are manufactured. The proposed branch plant will have a capacity of turning out 100 motors per day at the outset.

Sewell Cushion Wheel Co. Adds

DETROIT, MICH., Aug. 28—To care for growth of its cushion wheel business, the Sewell Cushion Wheel Co., maker of a special form of truck wheel with a shock-absorbing rubber portion, has started building operations on an extensive addition to its present plant here. The new building will be of re-inforced concrete and three stories high with dimensions of 70 by 74 ft. If present increase of business continues, the Sewell concern, it is stated, will tear down the old building after the addition is completed, erecting eventually a five-story re-enforced concrete structure by adding two stories to the new part and building five new stories replacing the old part.

$250,000 Plant for Sterns Tire

ST. LOUIS, MO., Aug. 28—The Sterns Tire & Tube Co., a subsidiary of the Efficiency Oil Corp., will build a four-story plant here costing $250,000. The structure, which will have a capacity of 1600 casings and 3200 inner tubes daily, will be 120 by 200 ft., and the site is at Kienlin Avenue and Terminal tracks.

The product will be known as Sternwear and the tubes will be sold under a guarantee of 20,000 miles of service without puncture, blowout, or rimcutting.

Mr. Sterns has closed a deal with Henry Matthews, Trenton, Ont., whereby the latter obtained the manufacturing and selling rights of Sternwear tubes and casings in Canada. Mr. Sterns says the consideration was in the neighborhood of $500,000. Mr. Matthews has organized the Sterns Tire & Tube Co. of Canada, and has begun work on a large plant at Trenton.

Koehler Absorbs Factor

NEWARK, N. J., Aug. 25.—The H. J. Koehler Motors Corp. has been formed here with a paid-in capital of $425,000 to succeed the H. J. Koehler S. G. Co. and the L. E. Schlotterback Mfg. Co. The Schlotterback company was the factor for the Koehler company, which designed and sold the Koehler 1-ton truck. The combination is for the purpose of increasing production.

H. J. Koehler remains the president of the new concern and the product and its price, $895, are unchanged. Mr. Koehler formerly handled the Ford, E. M. F., Buick, Hupmobile and Grant, introducing each of these into the Eastern territory.

Cleveland Makers Using Tents

CLEVELAND, OHIO, Aug. 26—Tents are being erected by several of the local automobile makers to take care of the heavy business this season. The tents are being used for storage and assembling. Among those using them are White, Winton, Jordon and the Baker-Rauch & Lang Co.

Locomobile Lamps Do Not Infringe Massachusetts Regulations

BOSTON, MASS., Aug. 28—Locomobile lamps do not infringe the regulations of the Massachusetts Highway Commission, according to a decision in a test case, just handed down.

Willis Is U. S. Rubber Purchasing Agent

NEW YORK CITY, Aug. 25—R. S. Willis has succeeded C. A. Emerson as purchasing agent of the United States Rubber Co. Mr. Emerson is retiring after 29 years' work with this company.

Tread of the Pennsylvania Bar Circle tire

Acme Truck Doubles Capital

Increase from $100,000 to $200,000—Plant and Output To Be Expanded

CADILLAC, MICH., Aug. 24—The Cadillac Auto Truck Co., this city, maker of the Acme truck, has voted to increase its stock from $100,000 to $200,000. One-half of the new stock will be sold in the near future and the shares, having a par value of $10, will sell for $11.50. No date has been set for the sale of the remaining $50,000 of new stock.

The company will soon start the construction of a new building, which will be 200 by 65 ft. Production is to be increased during the coming year and an other model, a larger truck, is to be added to the company's line.

Firestone to Add

AKRON, OHIO, Aug. 25—The Firestone Tire & Rubber Co., this city, has taken out permits for two buildings, aggregating in cost $105,000. The largest building will be five stories in height and will cost $70,000. This will be used for mechanical devices. The other building will cost $35,000 and will be an addition to factory No. 6.

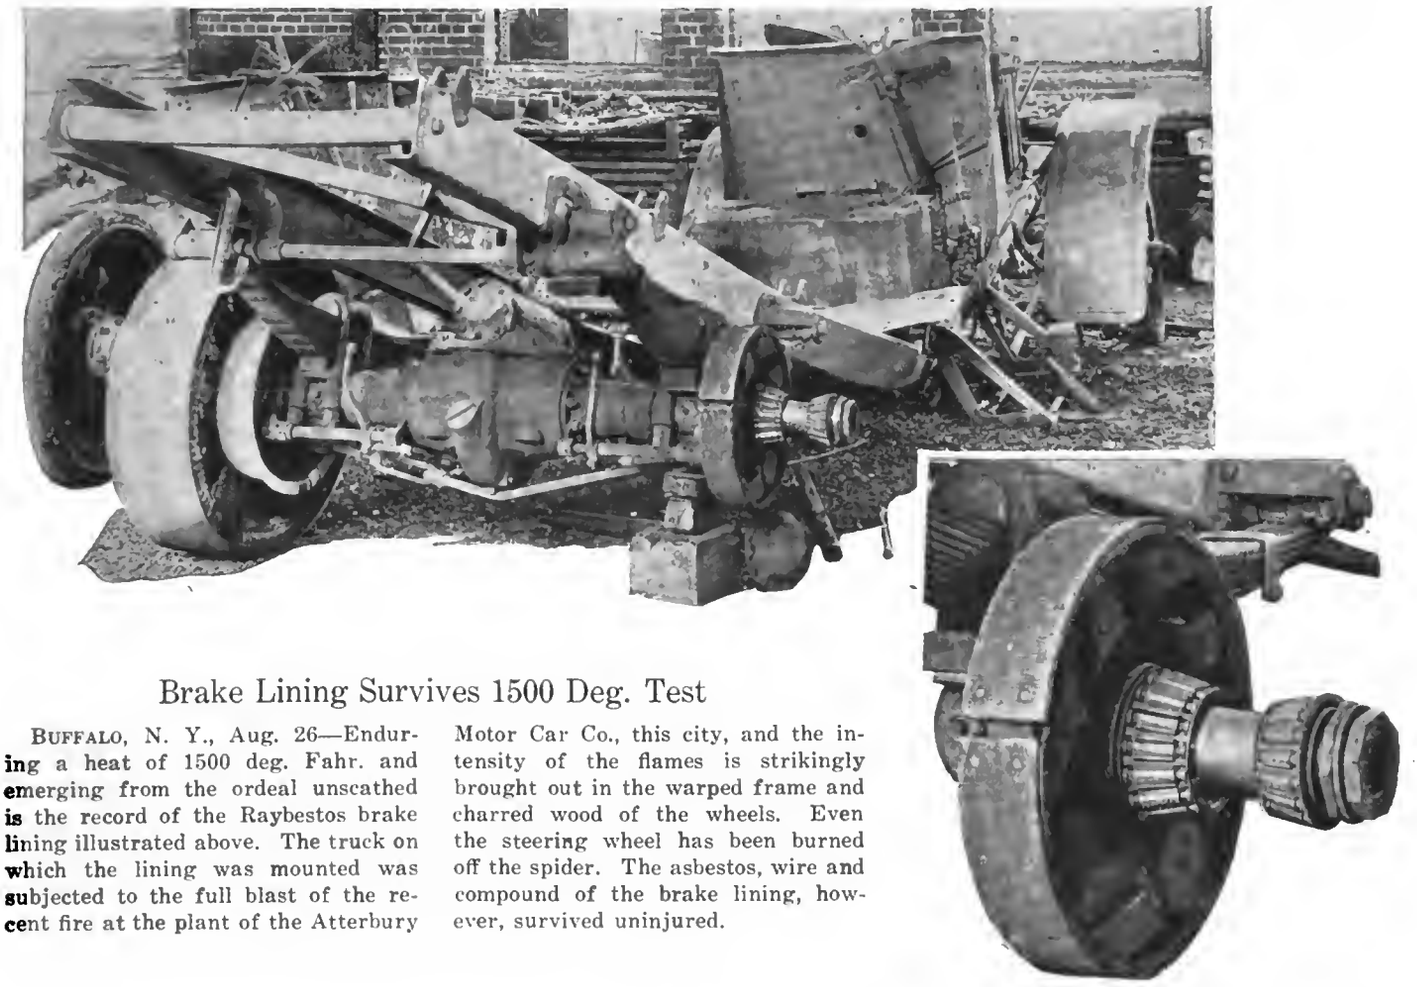
Miller Introduces Adona Tread for Repairing Worn Tires

AKRON, OHIO, Aug. 28—The Adona tread, which is stitched to an old tire carcass much as new soles are sewed to old shoes, has been brought out by the Miller Rubber Co., Akron, Ohio. The new tread consists of a complete new tread, containing fabric, cushion and breaker strip and, unlike retread bands, can be applied to a tire which has been worn down until the daylight shows through, provided the side-walls and bead are in good shape. In fact, it is practically a complete new casing, but without side-walls or beads. Although made with the Miller Geared-to-the-Road tread, these treads may be applied to any other make of tire.

Pennsylvania Has New Tread

JEANNETTE, PA., Aug. 28—The Pennsylvania Rubber Co., this city, has brought out a new tire with a tread of tough black rubber. The design, as indicated by the name Bar Circle, is a combination of heavy bars and circles. A 3500-mile guarantee is given.

The prices of these new tires have been figured on a basis of cost of production plus a modest margin of profit. The 30 by 3 in. is selling at $10.35 and the 30 by 3½ in. at $13.45, both considerably lower than on the Vacuum Cup and Ebony Tread types.



Brake Lining Survives 1500 Deg. Test

BUFFALO, N. Y., Aug. 26—Enduring a heat of 1500 deg. Fahr. and emerging from the ordeal unscathed is the record of the Raybestos brake lining illustrated above. The truck on which the lining was mounted was subjected to the full blast of the recent fire at the plant of the Atterbury Motor Car Co., this city, and the intensity of the flames is strikingly brought out in the warped frame and charred wood of the wheels. Even the steering wheel has been burned off the spider. The asbestos, wire and compound of the brake lining, however, survived uninjured.

Erbes To Concentrate in St. Paul

Waterloo Plant To Be Established in Duesenberg Factory

ST. PAUL, MINN., Aug. 26—L. C. Erbes, owner of the former Duesenberg Bros. plant in this city, is planning to remove to St. Paul the automobile plant he owns at Waterloo, Iowa, and to establish it in the Duesenberg factory.

Mr. Erbes will build automobiles in this plant, and as a result a $75,000 addition will be erected to accommodate from 100 to 150 workmen.

Some time ago Mr. Erbes bought up the Clarke-Carter Automobile Co. and the Cutting Car Co., and has been continuing manufacturing these machines at Waterloo, along with a car bearing his name. He plans to combine these under the name L-C-E, and to manufacture parts for all three cars.

—

Columbus Gear Co. Busy

COLUMBUS, OHIO, Aug. 25—J. W. Graham, vice-president and general manager of the C. A. S. Products Co., formerly the Foster Gear Co., has returned from Indianapolis, where he received a contract for 10,000 gears. Under the direction of Mr. Graham the plant has been placed upon an efficiency basis and the number of employees increased to 130, with a weekly pay-roll in the shop of over $2,000. Orders now on the books of the company will take the increased output of the plant from now until July 1.

—

Teetor-Hartley Doubles Capacity

HAGERSTOWN, IND., Aug. 24—The Teetor-Hartley Motor Co. is doubling its factory capacity at an expense of approximately $22,000. An additional 8640 sq. ft. of floor surface will be completed by Oct. 1 at a cost of $12,000 and machinery to the value of $10,000 will be immediately installed. Fifty more men will be added to the payroll.

—

Stephens Plant at Full Capacity

FREEPORT, ILL., Aug. 26—Orders were issued this week to the various departments of the Stephens Motor branch of the Moline Plow Co., to operate the plant to the fullest capacity. This will enable the company to market fifty to sixty cars a week. A marked shortage of experienced mechanics has affected the output, but the present force will be increased as rapidly as possible. Material is being ordered for next year when it is hoped to turn out several thousand cars.

Bela Body Company Buys Factory

Takes Over Standard Woven Fabric Co. Framingham Plant

FRAMINGHAM, MASS., Aug. 28.—The Standard Woven Fabric Co., which recently moved to Walpole, has sold its plant at Framingham and it is to be occupied by the Bela Body Co., of Amesbury, who will operate the whole property for the production of automobile bodies. The main building is of modern concrete construction, 53 by 224, three stories, having about 40,000 ft. of manufacturing space, and an attached fireproof boiler house, all equipped with sprinkler system and other modern conveniences. There is 108,720 ft. of land bordering on the railroad. Town assessment places $43,550 on the building and $7,570 on the land, making a total of $51,120.

—

Jordan Builds Five Cars a Day

CLEVELAND, OHIO, Aug. 26—Since Aug. 1 the Jordon Motor Car Co. has been producing five cars a day and it is expected that the maximum for this season, ten a day, will be reached early in September. The company has erected a

huge tent adjoining its new factory in order to extend its inspection facilities.

While 2600 dealer applications were received from the first advertisements of this company in THE AUTOMOBILE, *Motor Age* and *Motor World*, only 100 will be appointed for the present.

The Jordon Building Co. has taken formal title to the new plant of the Jordon Motor Car Co. from the Citizens' Savings & Trust Co., the indicated consideration being $75,000.

—

Metropolitan Motors, Inc., Organized

NEW YORK CITY, Aug. 26—The Metropolitan Motors, Inc., has been established with a capital of $1,000,000 to manufacture a light delivery vehicle and to take over the business of the White Star Motor & Engineering Co. W. C. Mack, one of the Mack brothers who started the Mack truck, is the moving spirit in the new venture, and it is said to be his survey of present market conditions that impelled the concern to undertake the production of a ½-tonner at a price which will be about $695.

To Continue White Star

The White Star trucks of 2, 3 and 5 tons' capacity will be continued. The stock in the new concern is all common. Production is expected to start between Oct. 1 and 15.

—

Dividends Declared

Linde Air Products Co.; 1½ per cent on preferred, payable Oct. 2 and 2 per cent on common, payable Sept. 30, both to holders of record Sept. 20.

Kelly-Springfield Tire Co.; quarterly of 1½ per cent on 6 per cent preferred, payable Oct. 2 to stock of record Sept. 15.

—

Redden Increases Capital to $500,000

DETROIT, MICH., Aug. 28—The Redden Motor Truck Co., producing the Redden truck maker, has increased its capital to $500,000 to take care of factory increases.

Rittman Gasoline 6.9 Cents per Gal.

—

Twenty Plants in Operation Indicate that Process Is Commercially Practical

WASHINGTON, D. C., Aug. 28—"It costs anywhere from 6.9 to 12.8 cents per gal. to make a gallon of gasoline by the Rittman process. The variation is due to the range of fuel-oil prices between 50 cents and $2.10 per barrel." This is an excerpt taken from a letter by Director Manning of the Bureau of Mines. Up to May 26, there were twenty factories licensed to use the Rittman process and the data is obtained from such of these that have actually been in operation. Summing up the results of the experiments thus far, Director Manning states:

Cost of Plants

"The capacity of a single tube was 1.55 per hr., or 37.2 bbl. per 24 hr., the loss 10 per cent, with a yield of 22 per cent gasoline, the balance being fuel oil. Estimated cost of a five-tube plant, $15,000. Estimated cost of building to house plant, $5,000. Total cost, $20,000. Monthly capacity, 5580 bbl. Deducting 10 per cent for shut-downs, leaves net capacity slightly more than 5000 bbl. Assuming yield of gasoline at 20 instead of 22 per cent, gives 1000 bbl. (42,000 gal.). Loss of 10 per cent equals 500 bbl. Residuum, 70 per cent or 3500 bbl.

Expense, 5000 bbl. fuel oil at $2.10 per bbl, $10,500; labor for one month, six men, $560; fuel, $200; electricity, $100; repairs, $100; 6 per cent interest charge and 6 per cent depreciation on first cost, $200; refining cost at 20 cents per bbl. (Oklahoma refining cost), $1,000; total expense, $12,660. Credit, 3500 bbl. residuum at $2.10, $7,350; net cost of 1000 bbl. (42,000 gal. gasoline, $5,310; cost of gasoline, 12.64 cents per gal.

Estimate based on oil at 50 cents a bbl.:

Expense, 5000 bbl. oil at 50 cents per bbl., $2,500; labor, $560; fuel, $200; electricity, $100; repairs, $100; 6 per cent interest charge and 6 per cent depreciation, $200; refining cost (Oklahoma refining cost) at 20 cents per bbl., $1,000; total expense, $4,660. Credit 3500 bbl. residuum at 50 cents, $1,750; cost of 1000 bbl. (42,000 gal.) of gasoline, $2,910; cost of gasoline, 6.9 cents per gal.

—

Gasoline Prices Stable

NEW YORK CITY, Aug. 29—Gasoline prices throughout the country remained, for the most part, unchanged last week. Wholesale prices in this section were stable, though the consumers were paying from 23 to 26 cents per gallon. Gasoline in New York, Long Island, Westchester and Connecticut is being sold by the Standard Oil Co. at 23 cents wholesale. In New Jersey the price is 21 cents. Retail prices there range from 23 to 25 cents per gallon. Texas and Gulf Refining prices remain the same as last week. Texas prices in this territory are 23 cents wholesale and 21 cents in New Jersey. Gulf Refining gasoline is selling wholesale in this territory at 23 cents and in New Jersey at 22 cents per gallon.

—

Copper Raised to 28 Cents a Lb.

NEW YORK CITY, Aug. 29—Steadiness marked the quotations on automobile materials last week. Though a few of the metals and oils made changes in prices, there was nothing unusual to change the general routine of the market activities.

Copper sellers and producers are now asking 28 cents a pound for November and December delivery. One large agency is out of the market entirely for all copper before December, stating that it is only receiving inquiries for December or January metal. The copper market is very strong and there is no indication of any let up in demand.

Aluminum 58 Cents per Pound

Aluminum has again reached 58 cents a pound. A report from Milwaukee states that the shortage of pig and sheet aluminum supplies has forced several manufacturers of aluminum goods in Wisconsin to close down temporarily. Stocks are coming very slowly and little is to be had at any price, it is said.

Reports from Pittsburgh claim that the automobile makers are now featuring the steel market there with requests to be permitted to close for their steel requirements over the first half of 1917. The steel makers have refused to consider 1917 steel for the automobile makers before Oct. 1. They are in the market for black sheets, and it is estimated that 1,000,000 tons will be asked by the leading makers.

Firestone Features Securities

1000 Mark Reached in a Gain of 65 Points—A Record High Price

NEW YORK CITY, Aug. 30—The automobile and accessory issues were lower and listless last week. Most of the prices were considerably lower than the previous week, especially on the Stock Exchange. The issues traded on the Curb were quiet at the beginning of the week, but have since picked up and have managed to make their losses smaller.

In marked contrast are the reports from the Cleveland Exchange, where most of the tire issues are traded in. Firestone common sold yesterday at $1,000 a share and established a landmark. That is the highest price at which a rubber stock ever sold in northern Ohio, and probably in the world. The market appreciation of the stock is indicated by comparison with the following figures in former years: In 1914 the high was 305½ and the low 247½; in 1912 the figures were 326 and 200½; and in 1910 127½ and 105.

Outside of the old Standard Oil, still traded here in the East, few issues have achieved Firestone's mark. There is a possibility of a readjustment of capital.

The rest of the tire issues were also strong and in large demand. Goodyear common reached 240, a gain of 5 points. Both the common and preferred of the Portage company rose 20 points.

Two more companies were added to the large list on the securities market, Republic Truck and Fisher Body both being introduced to the public. Two thousand shares of the latter stock were traded in at prices running from $38 to $38½. Republic Truck sold yesterday at 55.

Several of the Curb issues were the objects of aggressive professional selling yesterday and declined as a result. United Motors declined in the early dealings from 62¼ to as low as 60⅛, recovering to 60½. Chevrolet shared this weakness to some extent, selling from as high as 198 to as low as 193½ and closing at 197.

Chalmers, General Motors, Maxwell, Overland, and Studebaker were weak.

McClurg to Reorganize

COSHOCTON, OHIO, Aug. 25—Prior to a reorganization of the McClurg Tire & Rubber Co., a receivership has been asked by J. S. McClurg, L. C. McCurday and Dr. Jesse McClain. The plaintiffs are sureties on notes aggregating $17,500.

Gets 105 Counties in Texas

DALLAS, TEX., Aug. 25—The S. G. Davis Motor Car Co., Dallas, has been organized to control the sales and service departments of the Oldsmobile company in 105 counties of Texas.

$6,000,000 Capital for Pa. Rubber

Increase of $4,000,000 as Co. Is Reincorporated Under N. Y. Laws

NEW YORK CITY, Aug. 28—The Pennsylvania Rubber Co., Jeannette, Pa., has been reincorporated under New York laws as the Pennsylvania Rubber Co., with $6,000,000 capital. The previous capital was $2,000,000, divided into $1,000,000 common, $750,000 of which is outstanding, and $1,000,000 preferred, all outstanding. The incorporators of the new company are: H. W. DuPuy and S. G. Lewis of Jeannette and G. A. McLaughlin, this city.

Rush Motor Truck Co. Formed

PHILADELPHIA, PA., Aug. 26—The Rush Motor Truck Co., of Philadelphia, was recently incorporated for $500,000, to manufacture motor trucks and automobiles. The incorporators are Charles L. Guerin, J. D. Morelli and Emanuel Nageli, Jr.

Dile Motor Co. Petitioned

READING, PA., Aug. 28—A receiver has been asked for the Dile Motor Co., this city, The petitioner declares that the company's liabilities amount to about $15,000, while its assets are about $10,000.

Street Railways Use Motor Buses

English Lines Find Them Profitable Auxiliaries—American Cos. Adopt Them

NEW YORK CITY, Aug. 25—Several English street railway companies are finding the use of motor omnibuses profitable as feeders or auxiliaries to their rail service, and at the last annual convention of the American Electric Railway Assn., held in San Francisco, it was decided to investigate the possibilities of supplementing the regular street car service with motor buses in this country. Thus, the final outcome of the fight that the street car companies everywhere have made against the jitney bus may be the adoption of regular buses by the companies themselves.

The motor bus section of the Sheffield Corporation Tramways in England earned a gross profit of $26,850 during the business year ended March 25, 1916. The company operated twenty-one buses in regular service on ten routes totaling 30 miles in length, five of which extend for a considerable distance beyond the city limits. More than 500,000 miles were traversed by the buses during the year.

The Birmingham Corporation Tramways earned a profit of more than $50,000 in the year ended March 31. Its forty-one motor buses carried 6,300,000 passengers and covered 938,226 miles, earning a gross average revenue of nearly 25 cents per bus-mile, while operating expenses averaged less than 18 cents per bus-mile.

Other English systems operating motor buses are the York Corporation Tramway Department (four), Oldham county borough (three) and Bournemouth Corporation Tramways.

All of these municipally-owned services are finding that the motor bus is giving them a new lease of life, for without spending large sums on permanent track and overhead equipment, fresh revenue is brought in. The buses, while not always showing profits themselves, increase the traffic on the rail lines.

A year ago the United Railways & Electric Co., of Baltimore, organized the Baltimore Transit Co. and began operating twenty-five twelve-passenger buses to determine their desirability as an adjunct to the regular trolley-car system.

—

Making Tractor Cultivator

BLOOMINGTON, ILL., Aug. 25—The Illinois Silo Co., this city, has commenced the manufacture of a new tractor cultivator, patented by W. M. Springer, who for 25 years, was the designer of the Avery Mfg. Co., Peoria, Ill., and who will be in charge of the plant. The various sections of the tractor will be cast at various foundries and the finished parts assembled. The Springer machine will operate with any kind of gasoline or kerosene engine of more than 4 hp. The tractor complete with engine weighs from 2100 to 2400 lb. The frame is adjustable, so that it can be fitted to plows, cultivators, rakes, harrows, planters and other implements which the farmers use in their yearly labors.

—

Gehl Bros. Make Tractor

WEST BEND, WIS., Aug. 25—The Gehl Bros. Mfg. Co., West Bend, Wis., a large manufacturer of power and manual farm implements and machinery, is now engaged in the regular production of a new type of general utility farm tractor, propelled by a four-cylinder gasoline-kerosene engine, of 4¼ by 5¾ in. bore and stroke, and rated at 25-hp., at 900 r.p.m.

—

Ottawa Is Good Car Market

OTTAWA, ONT., Aug. 24—Ottawa people have been seized with a sort of craze for automobiles, and dealers have found this city is the most profitable field in the country. There are at present about 2500 automobiles and trucks in the city, or one for every forty of the population. Dealers declare that they have sold twice as many cars in July and August this year as in 1915. One dealer stated that his sales for the month of August are about 90 per cent better than last year. About 35 or 40 per cent of the cars sold by this agent were for commercial use.

In the whole Ottawa Valley as well as the city the demand for automobiles has been far ahead of last year. The good roads demonstrations and the prospect of better roads in the near future have awakened many to the desire of owning a car. A dealer who has been canvassing the country for a radius of about 50 miles around Ottawa says that there are very few farmers in that area who are not counting on buying an automobile before this time next year.

—

Kansas Expects 300% Sales Increase

TOPEKA, KAN., Aug. 14—Only the failure of the Kansas corn crop can prevent the automobile dealers of Topeka from selling from three to six times as many cars this season as were sold last year, is the opinion of local automobile dealers. The fall sales activity has begun and prospects point toward a wonderful season. Practically every agency is receiving or soon will receive large shipments of 1917 models. A number of dealers have begun distribution of cars.

N.Y.C. 6 Months Fees $1,100,203

116,482 Owners, 770 Dealers and 59,430 Chauffeurs Register from City

ALBANY, N. Y., Aug. 25.—Automobile owners in this city contributed $1,100,203 in registration fees to the State during the 6 months between Feb. 1 and July 31. These fees came from 116,482 owners, 770 dealers and 59,430 chauffeurs. During the month of July alone 5615 owners registered in this city.

Next to New York City, Buffalo turned in more money than any other city in the State, with Albany third. From Buffalo there were registered 85,417 owners, 744 dealers and 14,548 chauffeurs. The fees they contributed amounted to $661,118.

Albany had a registration of 70,263 owners, 803 dealers and 14,613 chauffeurs. Its contribution was $551,277. The total for the three cities was $2,312,599.

Curiously, New York City has far fewer dealers, in comparison with its population, than the other large towns of the State, having only a few more by actual count than Buffalo and considerably less than Albany.

—

232,017 Cars in Ohio

COLUMBUS, OHIO, Aug. 24.—W. H. Walker, Ohio registrar of automobiles, in a report covering the present year up to and including Aug. 24 shows that there are 232,017 automobiles in Ohio. Since the first of the year the department has registered 224,700 individual gasoline car owners and 4,443 electric owners. During the same period dealers to the number of 2874 have been registered. Now each dealer has at least one car and many of them have several demonstrators, but counting one car each there are 2874 cars owned by dealers. The total is 232,017.

—

7800 Cars in Alberta

EDMONTON, ALTA., Aug. 26—There are 7800 cars in Alberta as compared with 5835 last year, a gain of 1965.

Last year the number of cars bought in the fall months was quite large and these were to quite an extent purchased by farmers. This year the sale of cars to rural communities is large and all the manufacturing companies are receiving good business from country districts.

—

42,000 Cars in Georgia

ATLANTA, GA., Aug. 28.—According to records in the office of the secretary of state there are over 42,000 cars in Georgia against 25,000 for all of last year, a gain of 17,000.

36 Cars Entered for Cincinnati

Leading Racing Machines and Drivers in 300-Mile $30,000 Race

CINCINNATI, OHIO, Aug. 28—Thirty-six entries have been received to date for the 300-mile race to be held on the new Cincinnati 2-mile board speedway, Labor Day. The opening race is for $30,000 in prizes and the entries follow:

Car	Driver	Car	Driver

Road Race Postponed to Spring

SAN BERNARDINO, CAL., Aug. 22.—The Los Angeles-to-Salt Lake road race which was to have been held in October, has been postponed until next April. The weather has been so hot on the desert that it was impossible to get men to work on the road and put it in condition for the event.

50 Exhibitors at Indianapolis

INDIANAPOLIS, IND., Aug. 28—Nearly 200 products will be shown at the Fall automobile show, which will be given in a large tent close to the Coliseum in the Indiana State fair ground, Sept. 4 to 8. This will be the largest show ever staged by the Indianapolis Automobile Trade Assn., there being more than fifty exhibitors showing products of seventy different factories.

The accessories exhibit, which heretofore has taken up much space, will be quite limited to make room for the new models of automobiles.

38 Cars on Exhibition at Columbus

COLUMBUS, OHIO, Aug. 28—The usual fall automobile show, held in conjunction with the Ohio State Fair, started to-day in South Machinery Hall at the fair grounds in this city and will last for a week. The show is under the auspices of the Columbus Automobile Show Co. Thirty-eight cars and many trucks are being shown.

The following cars are on exhibition:

The cars shown were: Briscoe, Buick, Cadillac, Chalmers, Chevrolet, Cole, Dorris, Dodge, Dort, Detroit electric, Elcar, Elgin, Empire, Franklin, Haynes, Hudson, Jeffery, Kissel, Liberty, Madison, Maxwell, Marmon, Metz, Milburn electric, Oakland, Overland, Owen Magnetic, Packard, Paterson, Pathfinder, Pierce-Arrow, Reo, Roamer, Saxon, Studebaker, Velie, Westcott, Willys-Knight and many trucks.

Receiver for Twin City Speedway

MINNEAPOLIS, MINN., Aug. 25.—The succession of troubles of the Twin City speedway since its opening last fall has finally drawn it into the hands of a receiver. Bids for the sale of the plant in whole or in parcels have been authorized by the court and the sale has been put into the hands of Phil Herzog of St. Paul. No limit as to the date of sale has been given.

The local speedway was America's first concrete oval and cost approximately $603,000. The 2-mile oval finished in August, 1915, did not come up to expectations in regard to structure and public support. The last race on it, July 4, was a loss financially due to lack of attendance. The cement track at that time was just as rough as it was last year, little attempt having been made to improve it.

Hupmobile on Capital-to-Capital Tour for Good Roads

DETROIT, MICH., Aug. 28—A 25,000-mile capital-to-capital tour by a Hupmobile in the interest of good roads was officially started to-day at Washington, D. C. The plan is to visit the capital of each state and to invoke interest nationally in good roads through the state road officials and others having charge of road matters.

From Washington the car proceeds north to Annapolis, Md., and thence to Harrisburg, the capital of Pennsylvania. Following a visit to all of the Eastern and New England capitals, the route then proceeds to Albany and across New York State to Buffalo, where the car swings southward to Columbus and Charleston, W. Va., then back to Indianapolis, Detroit and Lansing. Thence the route goes westward northerly to Seattle and down the Pacific Coast to Los Angeles and back to San Francisco. Then the car is driven eastward via Carson City, Ogden, Salt Lake City and Cheyenne to Denver.

The route zig-zags north and south, taking in all of the capitals until it finally comes up through the Carolinas to Richmond, and thence back to Washington.

The trip is in charge of J. S. Patterson and the car is driven by C. E. Salisbury and George Lipe, both of Detroit, and the fourth member of the party is W. A. Krohn.

The reports to be made by the party are to be both written and photographic.

Races for Fords at Chicago

Five Events, 10 to 50 Miles, for Recent Models for Labor Day

CHICAGO, ILL., Aug. 29—Sanction has been granted by the American Automobile Assn. for a series of races for Ford cars to be held on Labor Day at the Chicago Speedway. The races, which will be open to Fords of 1913 or later manufacture, will be arranged as follows: 10-mile Chicago Championship; 20-mile Cook County championship; 30-mile Illinois championship; 40-mile Tri-State championship for Illinois, Indiana and Wisconsin cars only, and 50-mile Interstate championship for which the greatest number of prizes will be offered, including a Ford touring car.

This is the first time in America that a speed contest on a major track has been limited to cars of one make. Ford races have proved popular on the half-mile and mile dirt tracks of the County Fair Circuit and the promoters of the Labor Day event believe that a series of Ford races on the Chicago speedway will bring out a good crowd of Ford fans. Between 20 and 30 cars have been entered tentatively.

Two Killed at Kalamazoo

KALAMAZOO, MICH., Aug. 27—Jack Peacock and Marion Arnold were killed and eight others injured to-day when eleven of fourteen cars piled up at the first turn during the 100-mile race on the 1-mile dirt track at Recreation Park, this city.

The twelve-cylinder Sunbeam which Peacock drove skidded at the start of the race on the first turn and struck the fence. The car was overturned and thrown squarely across the track, and ten of the other machines plowed into it. The Stutz, driven by Andy Burt, whose mechanician, Arnold, was killed, was the first to strike Peacock's car. Peacock was in partnership with Charles Hanson under the style Hanson-Peacock Corp., Brooklyn, N. Y., National car dealer.

40 Exhibitors at Milwaukee Show

MILWAUKEE, WIS., Aug. 26—Forty dealers are exhibiting eighty-five makes of cars at the second annual automobile show in this city under the auspices of the Milwaukee Automobile Dealers, at the State Fair Park, Sept. 11 to 16. The big Machinery Hall is again being used.

New N. Y. Taxicabs' Rates Lower

NEW YORK CITY, Aug. 25.—Taxicab service at 10 cents a mile lower than the

old rates went into effect here today. Though there are only two of these new rate taxicabs in service at present, there will be 200 by Oct. 1. The Black & White Co., organized by New York and Chicago taxicab interests, owns the cars. The company's garage will be 310 to 326 West 68th Street.

The new rate will be 20 cents for the first one-third mile and 10 cents for each additional one-third mile. Thus, the first mile will cost 40 cents, and all miles thereafter will be 30 cents. The common existing rate is 30 cents for the first half mile and 10 cents for each additional quarter, with an extra charge when more than two passengers are carried. The new charge is regardless of the number of passengers.

The new taxicabs will have electric lighting and will have an electric device on the outside of the car which illuminates the numbers on the houses and assists the driver in readily finding places.

The car presents the appearance of a private limousine. In the winter it will be equipped with heating apparatus and rugs. It was the type of car that has been so successful in Chicago, the same interests being behind the enterprise jointly with the local concern.

—

Paris Buses Again Running

PARIS, FRANCE, Aug. 25. — The local motor bus service has been partially reestablished with a single route served by thirteen buses running on a 5-min. schedule. This service was withdrawn 22 months ago on account of the war. The newly established line is over the main boulevards from the Madeleine to the Bastille.

—

Electric Vehicles at Electrical Exposition

NEW YORK CITY, Aug. 29—Electric passenger and commercial vehicles, as well as accessories, will hold a prominent place in the New York Electrical Exposition at Grand Central Palace, Oct. 11 to 21. A test run is now being planned to be held during the exposition. The Electric Garage, this city, will have an exhibit representative of the work it is carrying on. Among the pleasure vehicles will be the Baker, R. & L. and Detroit cars. Among the exhibitors of commercial cars will be the General Vehicle Co., Walker Vehicle Co. and Ward Motor Vehicle Co. The Edison Storage Battery Co. and the Electric Storage Battery Co. will have exhibits.

—

47 Pathfinders Shipped to Petrograd

INDIANAPOLIS, IND., Aug. 30—The Pathfinder Company,. this city, has started a train load of forty-seven cars, both touring and roadsters, for Petrograd, Russia. These cars are for trade and not for army purposes.

Ideal Army Truck Is Evolving

—

Commercial Use of Such a Type Expected Within 2 or 3 Years

WASHINGTON, D. C., Aug. 26. — Military transport experts believe efforts to develop a motor truck capable of meeting the needs of the army campaigning along the Texas border and in Mexico will cause the manufacture for commercial use of an ideal truck within the next 2 or 3 years. The army transport board has been in session here recently considering the preparation of specifications for each type of truck required by the army, upon which truck makers will be invited to bid.

The board found that the tests to which the army trucks were subjected on the border and in Mexico were the most severe that had been had in any part of the world. The conditions of service were quite abnormal, yet the performance of some of the trucks was remarkably good. Experts of the S. A. E., acting on the suggestion of the board, now are on the Mexican border studying at first hand the unusual conditions of weather, sandy grit and alkali existing there with a view to the still further improvement of the army trucks.

—

Franklin Roadster $1,850

In the description of the new Franklin models published in THE AUTOMOBILE for July 27, the price of the four-passenger roadster was given incorrectly. This new model, for which the Franklin company is experiencing strong demand, sells for $1,850.

—

Durant Interests Back of Big N. Y. Building

NEW YORK CITY, Aug. 25.—Automobile dealers in this city whose leases are about to expire or who are having trouble finding storage facilities will be interested to know that an eight-story building, serving the dual purpose of storage and service, is being planned. Interests identified with W. C. Durant are backing this. The building will provide close to 500,000 sq. ft. of floorspace, and though it is backed by General Motors and Chevrolet interests, it will not in any sense of the word be a G. M. C. proposition, but will be open for all.

This building will occupy the entire plot of ground on Eleventh Avenue, from 55th to 56th Streets, with a 200-ft. frontage on the avenue and on each street.

A modern fireproof building is to be erected of either steel and concrete or steel and brick construction. Though the plan now calls for an eight-story building, it is likely that four more stories will be added.

Special high-speed elevator facilities will be provided. It is planned to divide the 40,000 sq. ft. on each floor into eight units, each unit being designed to provide both storage and service facilities.

—

N. Y. White Moves

NEW YORK CITY, Aug. 27. — Another break is about to occur in Automobile Row. The White Co., for 10 years located at Sixty-second Street and Broadway, has leased a large plot at the northwest corner of Park Avenue and Fifty-seventh Street, where it will construct a five-story building to house all the branches of its passenger car and truck departments. The plot has been leased for 21 years.

The impending removal of this company will mark the second important deflection from that district, the first having been that of the Simplex at the beginning of this month, when it located at Fifth Avenue and Fifty-eighth Street.

—

Buy Detroit Oldsmobile Branch

DETROIT, MICH., Aug. 28—An important change in local automobile circles has resulted from the buying out of the Oldsmobile factory branch by Wilbur H. Collins, son of R. H. Collins, former Buick sales manager and now a director of the General Motors Co., and F. J. Muellerschoen, who for several years was connected with the Philadelphia Buick branch. The Oldsmobile business will hereafter be conducted as a distributing organization with a territory including all of Michigan and nine counties in Ohio immediately adjacent to Toledo. R. C. Lowrie continues in the Detroit organization in charge of retail sales, and will retain the same selling staff.

—

Milwaukee Boosters' Tour Starts

MADISON, WIS., Aug. 28—If the enthusiasm which has marked the first day of the State fair boosting tour of the Milwaukee automobile dealers indicates anything, the 1916 fair should be the best in years.

Thirty-six cars representing the Milwaukee Automobile Dealers left this morning. Seven stops were made over a distance of 105 miles. At each stop the cars were parked in the center of the town and paraded throughout the downtown section. Stops to-day were at Waukesha, Oconomo, Johnson Creek and Jefferson for dinner, Lake Mills, Deer Field and Madison. To-morrow night's stop will be at Green Lake.

Factory Miscellany

Obenberger in New Forge Plant—The John Obenberger Forge Co., recently organized, with offices at 608 Majestic Building, Milwaukee, Wis., has occupied its new plant in West Allis, Wis., where it is turning out forgings for crankshafts, connecting-rods, worm shafts, gear blanks, etc.

To Make Accessories—The American Auto Trimming Co., Cleveland, Ohio, has been incorporated with a capital of $100,000 and will establish a plant in the factory building of the Properties Co. on East Seventy-ninth Street, for the manufacture of automobile accessories. Among those interested are Benjamin Gotfredson and Frank Joyce, both at present engaged in a similar business in Detroit.

Buy Hercules Personal Property—The personal property of the Hercules Motor Car Co., Louisville, Ky., has been sold at auction for taxes amounting to $5,582.42. It was bid in by the H. & P. Machine Tool Co., New York City, for $6,100. The property comprised a large quantity of machinery and office fixtures, but not the real estate.

To Manufacture Tires—G. G. Meeley of the American Auto Tire Co., 154 North Broad Street, Philadelphia, Pa., has purchased the old Patterson textile mills in Chester, Pa. The mills will be enlarged and converted into an automobile tire factory. The structure now consists of a main building, 316 by 76 ft., three stories; a two-story brick building, 188 by 80 ft.; a brick and frame building, 123 by 64 ft.; a brick building, 74 by 33 ft.; a brick boiler and engine house and a two-story brick and stone office building.

Takes Over Dimmer Business—The Auto Light Control Co., care of M. D. Elgin, 224 Charles Avenue, Detroit, has incorporated for $25,000, taking over the business of the Grand Rapids Dimmer Co. It expects to manufacture and sell automobile light controls and specialties.

Allen Co. to Make Trucks—The Allen Street Sweeper & Auto Co., Allentown, Pa., will open a plant for the manufacture of commercial vehicles and street-cleaning machines. H. S. F. Barner, 1421 Munroe Street, Allentown, general manager, was connected for 12 years with Mack truck company.

Wald Machine Adds—The Wald Machine Co., Sheboygan, Wis., maker of automobile specialties, has started work on the erection of its new machine shop, 80 by 100 ft.

Buick Constructing Office Building—Plans for the immediate construction of a four-story office building on the site of the present office structure have been announced by the Buick Motor Co., Flint, Mich., through General Manager W. P. Chrysler. The new structure will be 242 by 50 ft. and will be of fireproof construction of reinforced concrete, to cost $240,000. It is planned to start work between Sept. 1 and 10, with a view to completing the new quarters before the first of the year. A larger building is made necessary because the force of office employees has completely outgrown the present rather large quarters.

Falls Motors Opens Bids—The Falls Motors Corp., Sheboygan Falls, Wis., formerly the Falls Machine Co., has opened bids in the office of Architect A. C. Clas, Colby-Abbot Building, Milwaukee, for the construction of two new buildings, which will materially increase the capacity of the plant before the end of the year. Plans call for a motor assembly shop, 119.7 by 119.6 ft. in size, and a motor repair shop, 72 by 85 ft., of modern reinforced concrete and steel sash construction, with concrete foundations and floors. A motor testing shop, 250 ft. long, and having accommodations for 120 motors at a time, has just been completed. The city of Sheboygan Falls is starting work on extensions of the waterworks system, so that the plant will have adequate fire protection and water service. Several streets are being vacated and opened for the benefit of the industry.

The Automobile Calendar

ASSOCIATIONS

Aug. 28-Sept. 1—Milwaukee, Wis., Booster Tour of Milwaukee Automobile Dealers.

Sept.—Indianapolis, Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.

Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.

Oct. 2-7—Kansas City, Mo., Dealers' Show, American Royal Live Stock Show; Kansas City M. C. Dealers' Assn.

Oct. 13—Flint, Mich., Fall Meeting National Assn. of Automobile Accessory Jobbers.

Dec. 2-9—Electricians' Country-wide Celebration.

CONTESTS

Sept. 4—Elmira, N. Y., Track Race, Elmira Auto and Motorcycle Racing Assn.

Sept. 4—Cincinnati, Ohio, Speedway, Cincinnati Speedway Co.

Sept. 4—Des Moines Speedway Invitation Race. Limited to six entries.

Sept. 4-5 — Spokane, Wash., Track Race, Inland Auto Assn.

Sept. 9—Indianapolis Speedway Race.

Sept. 9—Newark, N. J., Track Race, Olympic Park, Racing Assn.

Sept. 16—Providence Speedway Race.

Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.

Sept. 29—Trenton, N. J., Inter-State Fair, H. P. Murphy, Racing Sec.

Sept. 30 — New York City, Sheepshead Bay Speedway Race.

Oct. 7—Philadelphia Speedway Race.

Oct. 7—Omaha Speedway Race.

Oct. 14 — Chicago Speedway Race.

Oct. 19—Indianapolis, Ind., Race, Indianapolis Motor Speedway.

Oct. 21 — Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.

Oct. 22-23—Los Angeles, Cal., Commercial Car Reliability Tour.

Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

April, 1916—Los Angeles to Salt Lake City Road Race.

GOOD ROADS

Sept. 1-9—Cincinnati, Ohio, Good Roads Exposition and Convention, Music Hall, Hamilton County Dixie Highway Council of Cincinnati.

Sept. 6-7—St. Paul, Minn., Good Roads Congress, Auditorium.

SHOWS

Sept. 2-9—Cleveland, Ohio, Show, Industrial Exposition and Fair, Edgewater Park.

TRACTOR

Aug. 28-Sept. 1—Indiana Tractor Demonstration.

Sept. 4-8—Madison, Wis., Tractor Demonstration.

Sept. 11-16 — Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.

The Week in the Industry

Trade Happenings

New England Trade Items—The Hawley-Cowan Co., Saxon agent, has moved into the building on Commonwealth Avenue vacated by the Cottrell Motor Car Co., that was handling the Pathfinder line.

The Becker-Stutz Co., Boston, Mass., has opened a branch at Providence with N. W. Rogers as manager.

The Worcester, Mass., Buick Co. has been formed, with C. M. Stanley, R. G. Clark and H. K. Noyes as officers. Mr. Noyes is the wholesale distributor of Buicks in New England.

The Drown Motor Car Co., Barre, Vt., that had the Buick agency, has sold its business to the Barre Garage Co. and H. G. Bennett.

D. E. Morgan has been appointed manager of the Metz branch at Providence, R. I.

The Autocar has been taken on by the Stoddard Motor Car Co., Springfield, Mass.

The Walter F. Kelley Co. has been organized at New Haven, Conn., to handle Vim trucks.

S. L. Rochette has given up the Ford agency at Lowell to take on the Chandler for that city, Nashua and Lawrence, in addition to the Dodge Bros. line. Harry Pitts has taken on the Ford.

The Redden Truck Maker has opened a Boston branch to handle the Massachusetts territory, with headquarters at 755 Boylston Street. J. B. McMahon, Jr., former manager of the New York branch, and N. J. Wallis, a Boston business man, are associated in the office.

The Henshaw Motor Co. of Boston has opened a branch at Lynn for the sale of Dodge cars.

C. E. Grimes has been appointed manager of the used-car department of the Cadillac Motor Co., Boston.

The Franklin Motor Car Co. of Boston has opened a branch at Worcester.

Recent Mich. Changes—A. C. Leverton, former general superintendent of the Chalmers Motor Co., Detroit, has been appointed to the position of factory manager of the Briscoe Motor Corp., Jackson. Leverton has had wide experience in his line, and previous to his Chalmers connection was works manager of the Cartercar Co. and before that general superintendent of the Brush Runabout Co.

W. F. French, a newcomer to the automobile field but a man who is thoroughly conversant with the purchasing end through mercantile experience in Chicago, has been made purchasing agent for the Bour-Davis Motor Car Co., Detroit.

New Jordan Dealers—The new Jordan Motor Car Co., Cleveland, has appointed the following distributors: John G. Dale, 240 West Fifty-ninth Street, New York City; Motor Car Sales Co., Milwaukee; Chicago Motor Car Co., Inc., Chicago; Decrow Motor Sales Corp., Buffalo, N. Y.; R. W. Immasche & J. A. Johansen, St. Louis.

Burd Issues Double-Utility Book—The Burd High Compression Ring Co., Rockford, Ill., has issued to dealers a book giving the piston ring sizes of all cars, and at the right-hand side of each page columns for reporting the stock of rings carried by the dealer. The book is unusually complete.

Meyrick Succeeds Brussel—L. Meyrick, formerly of the Lavine Gear Co., Racine, Wis., has succeeded J. M. Brussel as general superintendent of the Ferro Machine & Foundry Co., Cleveland, Ohio. The latter has taken a similar position with the Delco company, Dayton, Ohio.

Kansas City Changes—The Bond Motor Co. has resigned the agency for the Oldsmobile and will add the territories of Kansas and northern Oklahoma under the Saxon agency.

The Marion-Handley Sales Co. was incorporated at Jefferson City, Aug. 25, with a capital of $20,000 and the following officers: L. C. Cadenhead, president and manager; F. A. Britton, sales manager; Glen Bruner, counsel and director. W. B. Harrison will be city salesman. Other offices will be established at St. Joseph, Missouri, Lawrence, Topeka, Emporia, and Tonganoxie, Kan.

The Hiatt-Buick Co., Kansas City, Mo., handling retail sales of the Buick in Kansas City, is established at 1715 McGee Street. LeRoy Simons will be sales manager and J. B. Durkee will be outside salesman, traveling Jackson County. O. W. Hiatt, head of the company, was formerly manager of the retail sales department of the Buick Motor Car Co., Admiral Boulevard and McGee Streets, which hereafter will handle only the wholesale business of the territory. The used-car department of the Buick is also under the management of the new retail company.

The King Motor Sales Corp. has been organized and will take over the agency for King Eight, formerly handled by the Donnelly-Campbell Motor Co. The new company will move from 1706-1708 McGee to 1901-1903 McGee, where a building is being remodeled for the purpose.

Ohio News Items—A. G. Fischer, general manager of the Fischer Auto & Service Co., Columbus agent for the Chalmers, has leased the first floor of a large building at Third and Rich Streets, in which a modern service station will be operated.

The Cornelius-Browning Auto Co., Toledo, has taken the agency for the Liberty in northwestern Ohio in conjunction with several other makes of cars.

The Campbell-Gilchrist Sales Co., Columbus agent for the Empire, is now quartered in a large storeroom at 15-17 North Fourth Street. Richard Cott has been placed in charge of the service station.

The Falls Rubber Co. has leased space at 1844 Euclid Avenue, Cleveland, and will open a branch for the sale of its product.

The Torbenson Gear & Axle Co. has purchased the three factory buildings of the Samuel Austin Co., 152nd Street and Nickel Plate Railroad, Cleveland, which it will use as its own factory with the addition of another building. The site contains 4½ acres.

The Mutual Auto Supply Co. has taken a 5-year lease on a double store in the Keystone Building on Chester Avenue, Cleveland, Ohio, to which it will remove from its present location on Euclid Avenue.

St. Louis Items—The Byerly Auto Co., East St. Louis, Mo., has been incorporated to handle Oldsmobile and Mitchell cars. It succeeds to the business of J. H. Byerly, who also is a shoe merchant. A. L. Perkins is manager of the automobile company and the showrooms at Tenth and State Streets have been remodeled.

The Packard Missouri Motor Co. has leased 1801-1807 Pine Street, formerly Donnelly Automobile Co., showrooms, as used-car salesrooms.

The Park Automobile Co. is showing the twelve-cylinder H. A. L. cars, for which the company has been named agent.

Barker Joins Kentucky Wagon Co.—J. M. Barker, for a number of years identified with the I. H. C. truck line in Alabama and the South, has joined the Kentucky Wagon Mfg. Co., Louisville, Ky. He has enlisted in the field force of that company and will cover Alabama and Georgia.

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, SEPTEMBER 7, 1916—CHICAGO NO. 10

18,254 Carloads in August

N. A. C. C. Joins Chamber of Commerce of U. S.—Good Roads Courses in Colleges

CARLOAD SHIPMENTS OF AUTOMOBILES

Month	1916	1915
January	18,054	8,369
February	21,502	11,273
March	28,600	16,442
April	28,000	17,112
May	24,000	13,642
June	23,879	15,325
July	18,079	12,517
August	18,254	16,959

NEW YORK CITY, Sept. 6—Shipments of automobiles in August amounted to 18,254 carloads as against 16,959 in the corresponding month last year and 18,079 in July, 1916. Reports from the National Automobile Chamber of Commerce which held its monthly meeting to-day show that though there are 10,000 more automobile cars in service than last year, there still seems to be a shortage of freight cars. There will be a meeting of the traffic officials to-morrow to consider this.

The Chamber has become a member of the Chamber of Commerce of the United States, Washington, thus giving it more scope in national affairs.

Road Engineering Courses

R. D. Chapin, chairman of the Good Roads Committee, reported to the directors to-day that a movement has been started to encourage the universities and colleges of the country to provide specialized courses in highway engineering with a view to meeting the growing demand for trained road engineers.

As a result of inquiries to the various state highway commissions, it is found that there is a decided lack of sufficient men with technical training and practical experience in road work to meet the requirements.

Out of seventy-five universities and colleges heard from, which provide civil engineering courses, less than half provide for any specialization by students in highway subjects. Only four have special highway engineering courses leading up to degrees or certificates in this particular branch.

The committee is endeavoring first, to create a demand by students for such specialized instruction, and second, to encourage the colleges and universities to provide it.

A Mississippi Centennial Celebration is being promoted, to be held from December, 1917, to April, 1918. The Director-General of the celebration advises that about $1,000,000 will be invested in the event and that the exposition is ready to co-operate in a good roads campaign throughout the South in the hope of bringing 100,000 automobiles to the Mississippi Gulf Coast during the celebration. He asks for the co-operation of the automobile industry through the Chamber of Commerce and for suggestions regarding how to make this the greatest good roads and automobile event of the South.

—

Foote Becomes H. A. L. President

CLEVELAND, OHIO, Sept. 5.—A. Ward Foote has succeeded H. A. Lozier as president of the H. A. Lozier Co. Mr. Lozier resigned last week on account of ill health. C. C. Homan has been elected vice-president; E. J. Tilliton, treasurer; F. H. Ginn, secretary; and G. H. Bowler, general sales manager.

—

Abbott Buys 6 Acres in Cleveland

CLEVELAND, OHIO, Sept.1—The Abbott Corp., which recently moved to this city from Detroit, has purchased a 6-acre factory site on East 152d Street. The corporation plans to erect a $150,000 building.

$59,994,118 Profits for Ford

508,000 Cars Made in Fiscal Year—$100,000,000 Surplus —$52,550,771 in Banks

1916 FORD FINANCE FEATURES

Gross business	$206,867,347
Profits	59,994,118
Cash in banks	52,550,771
Merchandise and supplies	31,895,434
Invested in plants	17,293,293
Capital stock	2,000,000
Liabilities	18,127,312
Surplus	111,960,907

DETROIT, MICH., Sept. 4—Over $1,000,000 per week was made by the Ford Motor Co. during the fiscal year ending July 31, 1916, according to the financial statement just issued. The profit for the year amounted to $59,994,118, resulting from the sale of 472,350 Ford cars and parts. A total of 508,000 cars was manufactured for the fiscal year, but 35,650 machines, representing about 2½ week's output, were in transit and at the branch assembling plants at the close of the year.

$111,960,907 Surplus

Some stupendous figures are contained in the balance sheet of the corporation, which is capitalized at only $2,000,000 and has over $100,000,000 surplus at the present time. The assets include cash in the bank amounting to $52,550,771, merchandise and supplies valued at $31,895,434, accounts receivable of $8,292,778, and other lesser items. The liabilities amount to only $18,127,312, leaving a surplus of $111,960,907, after deducting $2,000,000 for the capital stock. The aggregate of the business done for the year reaches the staggering figure of $206,867,347.

The report also shows that the Ford

50% Stock Dividend for Paige

Applies to Stock Having Par Value of $10—Now Selling Around $55 in Detroit

DETROIT, MICH., Sept. 6.—The Paige-Detroit Motor Car Co. has declared a stock dividend of 50 per cent to holders of present stock of record on Sept. 9. This is the second stock dividend paid by that company in the last four months.

On May 13 the company gave a stock dividend of 80 per cent, and increased the capital from $1,000,000 to $2,000,000. At the same time the par value of the stock was cut down from $100 to $10 a share.

The present dividend applies to stock having par value of $10, which is now selling at about 55 on the Detroit Stock Exchange.

Peerless Starts Plant Expansion

CLEVELAND, OHIO, Sept. 1—The Peerless Motor Car Co., is planning the construction of several additions to its plant. The two three-story additions and one entirely new building are contemplated. Work will begin immediately.

Kissel to Add 14,000 Sq. Ft.

HARTFORD, WIS., Sept. 2 — Approximately 14,000 sq. ft. of floor space will be added to the plant of the Kissel Motor Car Co., Hartford, Wis., at once. Contracts have been let for the enlargement of the sheet metal and body building shops, and work is well under way. The new buildings are 77 by 123 ft. and 40 by 100 ft. in size. The improvement was projected earlier in the year, but work could not be undertaken because of the shortage of contractors' labor. The Kissel company is preparing an extensive building program to be undertaken within the next month and carried on throughout the winter.

Repair Work 85 Cents an Hour in Boston

BOSTON, MASS., Sept. 1.—Following a meeting of the Board of Directors of the Boston Automobile Dealers' Assn. held this week a uniform rate of 85 cents an hour for repair work will be charged in practically all of the service stations of the members beginning to-day.

Big Payrolls in Lansing

LANSING, MICH., Sept. 2 — Business conditions are far ahead of 1915 in this vicinity, according to payroll figures made public by the leading industries of the city. Reo has 1000 more men on its payroll now than it did a year ago and the Reo motor truck thirty-four more. The Auto Body Co. is employing practically double the number of men as compared with a year ago and would take more if the space were available for the many men needed. W. K. Prudden is employing 200 more men than a year ago and the Olds Motor Works, Auto Wheel Co., Bates & Edmonds have from fifty to 250 more men than last year. Actual figures of the Reo company show 3645 now as compared with 2652 for 1915.

American Tire Buys $90,000 Plant

PHILADELPHIA, PA., Sept. 2 — George G. Meeley, of the American Auto Tire Co., Inc., 154 North Broad Street, Philadelphia, Hugh B. Turner, secretary and treasurer of the company, and several others have purchased the old Patterson textile mills in Chester, Pa., which will be improved and enlarged on for the manufacture of automobile tires. The price given for the mills is $90,000. There are two main buildings, 76 by 316 ft.; a two-story brick building, 80 by 188 ft.; a boiler and engine house and an office building.

N. Y. Traffic Violations Decrease

NEW YORK CITY, Sept. 6—Speeding as a result of the several fines and imprisonment given violators during July has somewhat abated in this city. Arraignments for violations of traffic rules were less in August than in July, there being 1,219 as against 1,280. Speeding cases during August numbered 371 as against 461 in July. The total amount of fines paid to the Traffic Court was $13,567.

Herschell-Spillman Enlarging

NORTH TONAWANDA, N. Y., Sept. 2—The Herschell-Spillman Co. is building an addition to its already large motor manufacturing plant.

Seagrave Finishes Addition

COLUMBUS, OHIO, Sept. 2.—A new addition to the plant of the Seagrave company, manufacturer of motor-propelled fire department apparatus of all kinds, has been completed in the form of an added story, which will be used for offices. The offices which are being vacated on the first floor will make room for an addition to the paint shop.

$500,000 Additions for Goodrich

AKRON, OHIO, Sept. 1.—The B. F. Goodrich Co., this city, will erect new buildings costing $500,000 in the next few months. One new factory building, south of the present factory No. 10, will cost $415,000. It will be six stories in height, and will be used for general factory purposes.

An addition to factory No. 9 will cost $44,000 and another addition to No. 10 will most $38,000. Both are one-story additions.

Torbensen Axle Co. Formed

Organized with $1,750,000 Capital—To Take Over Gear and Axle Co.

CLEVELAND, OHIO, Sept. 1.—The Torbensen Axle Company, this city, has been formed with a total authorized capital of $1,750,000, to take over the Torbensen Gear & Axle Co., with its main plant now in course of completion on East 152nd street, this city.

Of the authorized capital $1,000,000 is preferred and $750,000 common, but only $500,000 of preferred and $395,000 are to be issued at this time. The $395,000 of outstanding capital will cover the taking over of the old company and will also provide $400,000 of new capital. This has been practically all disposed of at private sale and there will therefore be no public offering of the securities.

This company has been located in Cleveland about one year, originally on East Seventy-second street, but more recently a 4-acre site was acquired on East 152nd street, on which a large plant with 60,000 sq. ft. of floor space is now being completed.

Ohio Rubber Plants Contribute 61% of Wages

AKRON, OHIO, Sept. 4.—Of the $29,030,965 paid out in Summit county in wages during the past year, 61.1 per cent, or $21,733,088, was paid out by rubber plants. The second largest payroll in the county is given by foundry and machine shops, much of which is connected with the automobile industry.

In Lucas county, where Toledo is located, $10,089,214 out of a total of $35,343,043 is paid out by automobile factories.

Goodyear Employees Get More Land for Homes

AKRON, OHIO, Sept. 5.—An addition of 350 acres has just been made to Goodyear Heights, a tract of land laid out for workmen in the plant of the Goodyear Tire & Rubber Co. The home building plan for employees has been in operation for 3 years, the original plot being 100 acres. On this land employees of the Goodyear company can build their own homes on the basis of rent without any large first payment.

Zimmerman Joins Milwaukee Engine Co.

MILWAUKEE, WIS., Sept. 6—B. D. Zimmerman has been elected secretary and treasurer of the Milwaukee Auto Engine & Supply Co., this city.

Saxon Co. to Build New Plant

Buys 38 Acres of Land—Work on New Plant to Start About Oct. 1

DETROIT, Sept. 4—Positive confirmation of the report that the Saxon Motor Car Corp. is to build a new plant was obtained to-day with the information that a tract of land 38 acres in extent has been procured. It lies on the western side of the city and just outside of the present city limits in what is known as Spring Wells. It is a block north of Michigan Avenue along the railroad.

Work on the new plant is to start about Oct. 1, and according to President Harry W. Ford, the new home will be about four times the size of the present quarters, having about 600,000 sq. ft. of floor space. It is the aim to be in the plant by Jan. 1, to take care of next spring's production rush. The exact size of the buildings has not been determined, but it is known that they will be of modern factory design of brick, concrete and steel. Two manufacturing buildings, one two stories high, and the other one-story will run the entire length of the property along the Belt Line railroad.

Other industries have recently located on the west side of the city, the chief advantage of this side being that the shipping of products is quickened about 24 hrs., as is also the receiving of shipments. It takes a day to move them across the city to the eastern end, it is stated. The Springfield Body Co. is building a plant in this district also.

—

Covert Gear Co. Is Incorporated with $1,000,000 Capital

LOCKPORT, N. Y., Sept. 1.—The business of the Covert Motor Vehicle Co., this city, was recently reincorporated as the Covert Gear Co., and its capital stock was increased to $1,000,000. It is erecting an additional factory building at a cost of over $50,000, and on completion about Oct. 1 will devote it to the manufacture of transmissions.

—

Chandler Plans Additions

CLEVELAND, OHIO, Sept. 1—It is reported that plans are now being drawn for several large additions to the plant of the Chandler Motor Car Co.

—

Victor Motor Co. to Build Automobiles Near Wilmington

WILMINGTON, DEL., Sept. 4.—The Victor Motor Co. has been formed with a capital of $2,000,000 to take over the business of the Victor Car Co., of Philadelphia, and has bought twelve acres of land on the Delaware River at Grubb's Landing, north of Wilmington, to build a plant for the manufacture of moderate-priced automobiles. This company expects to build about 5000 cars a year.

The officers of the new company are C. P. Grandfield, president; C. V. Stahl, vice-president; H. H. Skerrett, treasurer; Regnault Johnson, secretary; and W. H. Bischoff, director.

—

Star Motor Co. To Build Automobiles and Trucks

CINCINNATI, OHIO, Sept. 2.—Steps have been taken for the incorporation of the Star Motor Co. with a preliminary capital of $200,000 for the purpose of manufacturing and assembling automobiles and trucks. The incorporators will be Louis Tyroler, W. Rudisill, J. A. Finn, W. Cayce and William Fischer. It is planned to locate a factory in Cincinnati, the location to be announced later.

—

Rubber Products Capital $500,000

AKRON, OHIO, Sept. 1—The Rubber Products Co., Akron, has increased its capitalization of $300,000 to $500,000. In the three years since the company has been formed, eleven per cent has been paid in cash dividends and recently a 20 per cent stock dividend was distributed.

A stock dividend of 10 2/3 per cent is anticipated with the issuance of more paid-in stock at par.

Wooler Designing Light Six

CLEVELAND, OHIO, Sept. 1—Ernest Wooler, automobile consulting and designing engineer, has opened an office on St. Clair Ave., this city.

It is rumored that he is designing a light six which will be placed on a production basis this winter. Cleveland capital is supposed to be back of this proposition.

—

Boston Dealers Back Jordan Agency

CLEVELAND, OHIO, Sept. 1.—The Jordan car manufactured in this city has secured a Boston agent, which is rather unusual, in that those back of the company handle other makes of cars. These include: J. H. Macalman, Stearns dealer and president of the dealers' association in Boston; J. W. McGuire, Pierce-Arrow agent, who is treasurer of the association; and J. H. Johnson, Buick, who is a director. F. A. Hinchcliffe, who has been manager of the Winton agency in Boston, has resigned to take the management of the Jordan agency.

Other Jordan dealers just appointed are: Chicago Motor Car Company, Chicago; Motor Car Sales Company, Milwaukee, Wis.; George R. Bentel, San Francisco, Cal., and the Decrow Motor Sales Corporation, Buffalo, N. Y.

Howard Car on Market

Buggy Co. Capitalized at $500,000 to Assemble Car—Starts Work

GALION, OHIO, Sept. 6.—The A. Howard Co., this city, has been formed to take over the buggy business of Adam Howard and also to manufacture automobiles. The company is capitalized at $500,000, divided into $300,000 common and $200,000 preferred. A. Howard has been made president and general manager, R. W. Johnson vice-president, and A. W. Monroe secretary and treasurer. These parties, with F. E. Garn, Plymouth, Ind., will constitute the directorate.

The new company will take over the entire plant, stock, etc., of Adam Howard, who established his buggy business thirty years ago.

The automobile will be an assembled product, and will be known as the Howard. The style of the bodies has not been definitely decided, but the car will have a 112-in. wheel base, equipped with a 35-hp. motor.

Operations will be started at once. The company will start without a penny of indebtedness, and will practically have $500,000 with which to begin operations.

—

Paige-Detroit Roadster on Transcontinental Run

NEW YORK CITY, Sept. 6.—A Paige-Detroit roadster started to-day at 2.35 p. m. on a transcontinental run to San Francisco via the Lincoln Highway. The car was checked out by the Automobile Club of America. There will be four drivers. Joseph Nickrent and Robert Evans started the trip.

—

$750,000 Goodyear Plant for East Toronto

EAST TORONTO, ONT., Sept. 6.—The Goodyear Tire & Rubber Co. will build a plant in this city at a cost of $750,000.

—

General Tire to Increase Capital

AKRON, OHIO, Sept. 1—The General Tire & Rubber Co. is contemplating an increase in its present investment of $196,000 to an outstanding capitalization of $300,000 common and $200,000 preferred stock.

—

Dealers To Exhibit at Maine Fairs

AUGUSTA, ME., Sept. 2.—Automobile dealers in Maine are planning to take advantage of the county fairs throughout the state by placing exhibitions at some of the larger ones. There are fifty-four fairs scheduled and they all run for 3 and 4 days.

ACCESSORIES In South America

No. III

Goods Must Be Properly Packed—Business Methods Required —Custom House Broker Indispensable

By David Beecroft

IN doing business direct with South America, every attention must be given to the proper packing of goods and also to mailing the bill of lading, so that these will be in the hands of the purchasers as soon as the goods arrive. Much trouble is occasioned by bills of lading not arriving until weeks after the goods have arrived in the custom houses.

How to Pack Goods

With regard to packing goods, it is essential that you keep in mind the supreme importance of weight, as 99 per cent of the duties are paid according to weight. To simplify this you should pack all goods of the same kind together, and give the stated weight, in order to lessen loss of time in the customs.

There are three weights in connection with sending goods to South America. They are the net, legal and gross weight, defined as follows:

1. Net weight, the exact weight of the article.
2. Legal weight, the weight of the article and the wrapping you sell it with. In case of a spark plug it is the pasteboard box. With a carbureter it may be a similar box.
3. Gross weight, the weight of the article, its wrapping, and lastly the large wooden box or crate in which the shipment is sent.

You always pay duty on the legal weight, that is, the article and its immediate wrapping.

Be careful to give weight of the different groups of arti-

General view of the coffee country in the State of Sao Paulo, Brazil. This State, which is larger in area than all of New England, is the greatest coffee-growing area of the world. In parts of the State coffee takes the same place that corn takes in Southern Illinois. As far as the eye can see are endless rows of coffee. The soil is reddish colored similar to that of parts of New Jersey or in parts of Georgia. This soil is declared to be the best for coffee culture of any soil in the world

cles you are forwarding. Thus, if your entire shipment is made up of

10 doz. screwdrivers
12 doz. spark plugs
100 sets Weed chains
60 hammers

weigh each of the groups separately, and so enter them on the bill of lading with the weight opposite.

The reason is that on each of these groups you pay a different custom rate. For example, the Argentine custom house values a hammer at 20 cents per kilo (2 1/5 lb.) and you pay a 25 per cent duty on this valuation. On screwdrivers valued at 60 cents per kilo you pay a 25 per cent duty on this valuation.

Spark plugs are valued at $1.10 per kilo, and you pay 10 per cent on this valuation.

So all through the car and through the list of accessories you find different schedules of values and different rates of duties. On steering gears valued at 60 cents per kilo the rate of duty is 10 per cent. On motor parts the valuation is $1.10 per kilo, and the rate of duty 10 per cent. The rate on axles is the same as on steering gears. To all of these duties is an extra war duty of 2 per cent, put on some years ago, and which the government has apparently forgotten to take off.

Numbering Crates

In crating goods for shipment by steamer, number each crate in sequence. If you have four crates, number them No. 1, No. 2, No. 3, and No. 4.

Be sure, on your bill of lading, to use this same numbering scheme. If you do not, trouble will follow. We know of one Argentine supply house that was put to an expense of nearly $70 solely because there were five different cases marked on the bill of lading, but only four cases shipped. The error was due to the shipping room crating packages No. 3 and No. 4 together. The custom authorities could not understand the situation. The supply dealer lived in Cordoba, and, as there is no custom house there, he had to make the trip to Buenos Aires to get the matter right. The total expenses totaled $70.

Tardy Bill of Lading

If the bill of lading does not arrive with the goods there is danger that the buyer will have to pay a 2 per cent fine to the custom house. To avoid this the custom house demands a valuation of the goods at the end of 8 days. The receiver of the goods may present a petition asking for 30 days' grace, which is granted.

These are only a few of the troubles that the receiver of the goods meets with in the custom house where necessary bill of lading and other documents do not arrive.

You must pay for storage in the custom house at the rate of 30 cents gold per cubic metre per month for 6 months.

If the goods have to be moved in the custom house, you pay at the rate of 60 cents per cubic meter.

You pay a statistical charge at the rate of 20 cents per $100 value.

If a crane has to be used in unloading, you pay for that.

There is custom house stamp paper, cartage, lighterage, and lastly, the commission to a custom house broker.

Get Custom House Broker

The custom house broker question is an imperative one to any concern going into the South American business and establishing your own agents in any of the countries. It is practically impossible for your agent to get goods through the custom house alone. You must employ a broker. No firm doing business in Buenos Aires or other cities tries to do otherwise. These custom house brokers are the "open sesame" to the custom house. They know exactly what to do and how to do it. You pay them a stipulated sum and they look after all of your customs. You hand the bill of lading and other documents over to them and they deliver the goods to your door. They do it quickly. You save the cost in time in a few months. Get one of the best available brokers for this work.

If each of the 30,000 automobiles in Argentina used six

This general view of the coffee country in the State of Sao Paulo, Brazil, gives a good conception of this most fertile section of the great country of Brazil, as this is the premier State of the country. It is in this State that more U. S. A. automobiles are being sold than in any other part of Brazil. This is a greater market than Rio de Janeiro. This State is wealthy and has a very high-class business sentiment. Not only is there a good market for our cars but also a big motor truck market

This scene shows coffee picking time in the State of Sao Paulo, Brazil. Wide avenues or roads cut through the great coffee areas, these roads being wide enough for a team of horses or oxen drawing the wagons which carry the coffee to the house and barns of the owner. In coffee picking time the country is literally filled with coffee pickers. The small bean does not grow in a pod like beans or peas, as is generally imagined, but the halves of the bean are inclosed in a single globular husk. These husks are pressed off by squeezing between the thumb and first and second fingers. The husk falls to the ground, no effort being made to prevent it falling on the ground, in fact, that is the way coffee picking is carried on. The coffee bushes are often 12 or 15 ft. high and short step ladders are needed in the picking. Coffee picking is naturally one of the big industries

tires in a season, it means 180,000 pneumatic tires. But the pneumatic tire business is not ours. France used to have the big hold, but since the war the French Michelin has naturally lost heavily, but the U. S. A. Michelin factory has fortunately taken up a large percentage of this. Italy has jumped heavily into the tire business in the last 2 years, Perelli being very active in all South American countries.

Our own U. S. A. tire people have been more alert than all of the other accessory people put together. As previously stated, Goodrich has been there for several years; Goodyear just got under way in Buenos Aires a few months ago and now has a fine establishment in the heart of Buenos Aires; Fisk has made particularly rapid progress in many parts of South America within the last 8 months and is doing a fine business. Firestone has been opening agencies for several months. United States Tire Co. has just got well under way in Rio and is doing the biggest business of any of our tire houses in the Brazilian metropolis. Republic has been well established in Chile for nearly a year, but has not yet got under way in Brazil, Argentina or Uruguay. A few other tire concerns have had their representatives there during the past 8 months. It can be said that to-day the U. S. A. tire concerns are on the job in South America and that in nearly every case they are making good.

Use Tire Signs

That we are not so good merchandisers of our wares in foreign lands as England, Germany, France, Italy and Belgium is well shown in the tire business. You cannot go into an automobile supply house in any of a score or so of cities in Brazil, Argentina, Chile and Uruguay without coming face to face with Michelin tire signs. You meet them in every garage, and I visted several score. You meet them in many of the car agencies. You meet them in little towns of 10,000 population, where there is not a garage in the place but where you can buy gasoline and Michelin tires. Perelli has equally good signs, but they are not so widely distributed. Dunlop tires are well advertised. You meet roadside signboards with huge Dunlop ads just as we see many brands advertised in the U. S. A.

The Michelin garage signs are not elaborate. They are plain, very clean and businesslike. They are white and blue enamel. Those for the outside of garages just have the words "Michelin Tires." They are generally round and have large letters. For the inside of garages you will see these signs, perhaps two or three of them in one place. They are ornamental. You may also see other blue and white enamel Michelin signs with the celebrated Michelin twins. These signs are not of billboard size but of conventional poster size, so that it is possible for the garageman or the supply house to hang them in a conspicuous place.

Enamel Signs Best

Our U. S. A. tire people are hopelessly behind in signs of this kind in South America, and if the signs have been sent they are not being used. We heard of one place where one of our large tire makers sent a supply of billboard signs 18 or 20 ft. long and 8 or 10 ft. high. Such signs are useless. You cannot use them in a garage or salesroom. The dealer will not rent a signboard for them.

Send clean-cut enamel signs to Argentina, Brazil, Chile and Uruguay and to the other countries in South America that you are doing business in. Get good-looking signs. The Latins of these countries have a strong artistic temperament. They know a sign that has been made by a cheap painter and one that has been designed by an artist. Send the artistic sign. It must not be elaborate. Make it plain, simple art. It will prove a good seller.

A word of advice to tire makers in the U. S. A.:

Look carefully into every agency you place in South American countries. Do not imagine that because you are signing up with the biggest firm in the city you are getting the best

representative. Some serious errors along this line have been made. Here is one: We know one place in Brazil where one of our largest tire makers signed with the largest concern in the city in question. That concern also handles a leading make of European tire. The understanding was that the U. S. A. tire was to be pushed and the European one sidetracked. I happened into that place and asked for tires. I was shown the European brand; in fact, two European brands. I then asked if he did not handle a U. S. A. tire, and he said he just had a few but was not stocking them heavily. I looked around for European tire signs and saw three facing me. There were more of them in the stockroom and there were others in the office. I looked for the U. S. A. tire sign, but there was not a sign of any nature any place. I asked for literature, and the manager was not able to give me any. That is one way not to get into the South American tire field.

I will cite a parallel that happened a few years ago in the motor car field in a South American city. The agent in question had the Pope-Hartford agency and was doing a fair business. He was about the strongest agent in the city. Hearing that the Cadillac was looking for an agent, he got it also. For several years he pushed the Pope-Hartford and smothered the Cadillac. He took the Cadillac agency solely to keep it out of the hands of other dealers. He did not want it to become a rival of his. This is not a hearsay story but one that the agent tells himself, now that the laugh is on him in that he used poor judgment in smothering the Cadillac.

Smothering Our Tires

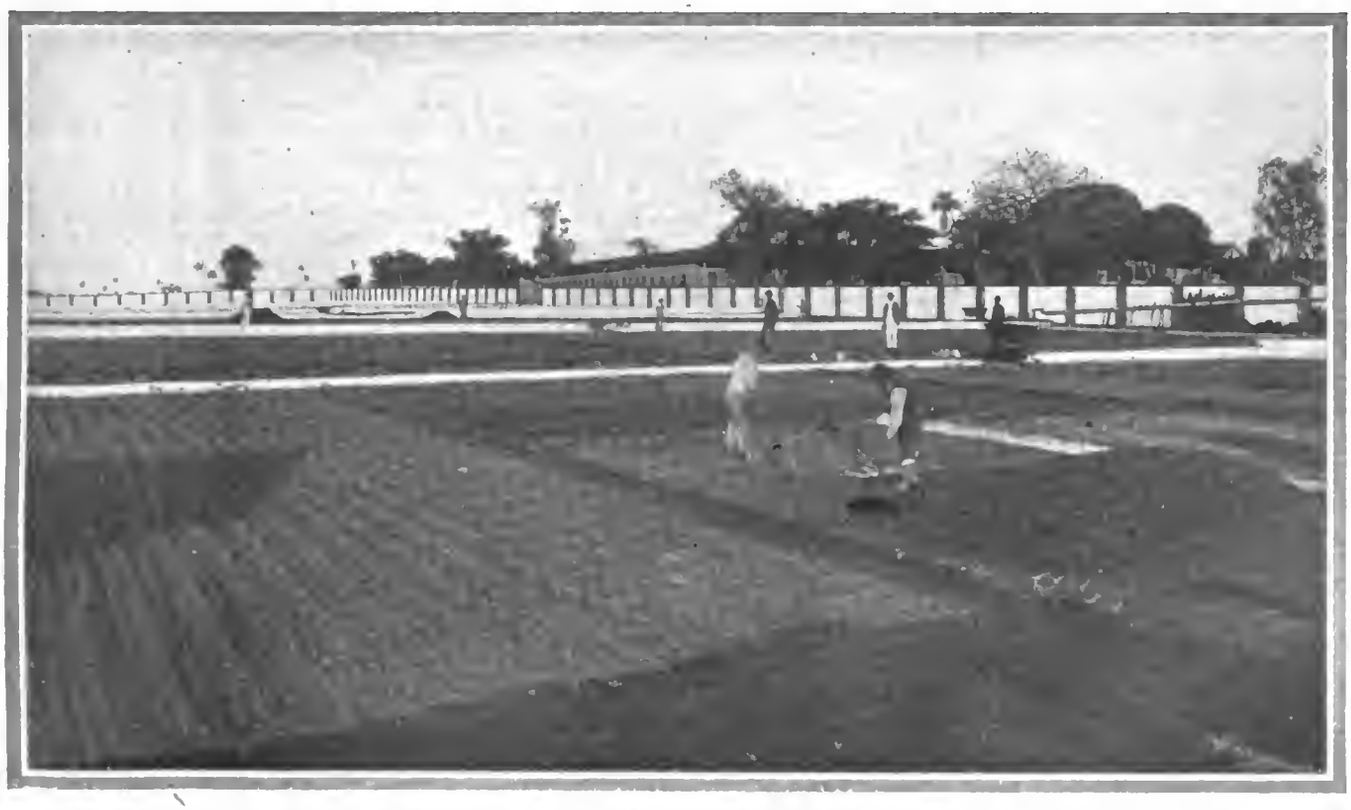
This smothering program is being carried out with some of our tire people, and it is also being carried out with a few of our automobile concerns. There are three or four makes of U. S. A. cars that are in the hands of very powerful agents whose national patriotism for European countries is so strong that they prefer to suffer themselves rather than see some of our cars get in ahead of certain European makes. Our makers have in a few cases prided themselves on getting such excellent connections, but they have only been hoodwinking themselves.

The tire business in South America is to-day a business worth having. We are getting it so easily that we scarcely know we have it. But, bear in mind, we are getting it due to the misfortune of European countries. Perhaps after the war we cannot only hold what we have but can keep on gaining. We hope so. But to do that we must quote our best prices. A few of our companies are taking orders at rather high figures. They say, "We can get the prices; why not charge them?" True, you can get them to-day, but it is questionable if you will get them when the war is over. The South American dealers must have tires. They cannot get them from Europe and must get them from the U. S. A. But if we overcharge to-day they know we are overcharging, and will not buy from us to-morrow when the Europeans come back into the market.

One large supply house admitted to me that it was not making a single cent out of its U. S. A. tires. In response to a question as to why carry them when they were not making money out of them the answer came promptly, "We cannot get interest on our money in the banks. We must give our customers service, and our money might just as well be circulating in tires as in anything else." This is the statement you hear in many places. They are all living to the end of the war, when they hope for a more or less return of old conditions. What will then happen is a mystery.

In the meantime the tire demand must be met. The cars in use require tires and those on the ground are reaping the profits. The natural resources of Brazil are such that there is bound to be a large export business to Brazil in the future. At present our trade relations with Brazil are of the pleasantest nature and there is no time better than the present to make a start in getting properly established there.

(To be Continued)



This is a common view at the home of one of the coffee growers. This is a large brick, cement or hard dirt area on which the coffee is spread out for drying. The magnitude of these areas appears in this illustration. In many places acres are so occupied. The coffee is handled in various ways while on these drying grounds. On every large coffee farm these drying areas are as much a part of the plantation as are the house or barn of a modern Wisconsin farm

S. A. E. Talks Trucks and Engines

Discussion of H. L. Horning's Paper on Truck and Tractor Engines Brings Out Troubles with Vehicles on Mexican Border, Due to Rivalry and Carelessness of Drivers

MILWAUKEE, WIS., Sept. 2—Inside facts on the operation of war trucks with the Villa punitive expedition in Mexico came to light to-night in the third quarterly meeting of the midwest section of the Society of Automobile Engineers in Milwaukee.

It was stated that a great deal of the trouble with all makes of trucks operating between the base at Columbus, Tex., and the head of the column in Mexico, was due to the fact that some of the trucks were driven by civilian chauffeurs from the factories who were paid three times as much as the soldier drivers, called sergeant chauffeurs.

Naturally there was much hard feeling on the part of the soldier drivers and they did not take much trouble to care for the trucks properly. Several weeks on the border brought about instances in which the trucks were deliberately wrecked by the disgruntled sergeant chauffeurs, according to Jerry Decou of Jeffery, who expressed the belief that much avoidable trouble came through rivaly between drivers of different makes of cars.

This caused drivers to attempt to get to the bases first and instead of driving at the specified speed of 14 m.p.h., speeds of 24 miles were made. This fact, together with the work of the alkali dust, 2 ft. deep in places, made the operating conditions particularly bad.

Decou stated that he saw more than ½ in. of mud in the crankcases of some of the trucks at the U. S. Government service station. Sometimes the trucks came in without a drop of oil in their engines and some with only a thimbleful.

Decou added these statements on the mud and oil in confirming some statements of H. L. Horning of the Waukesha Motor Co., whose paper, Trucks and Tractor Engines, was the feature of the meeting.

Owing to the fact that many of the engineers were unable to attend the meeting on account of fear of the impending strike, the attendance was not as great as expected. After the paper and its discussion were heard, the engineers inspected the electrical and automobile laboratories of the Central Continuation School, in the auditorium of which the meeting was held.

The purpose of the paper the first installment of which follows, was to illustrate the differences in demands on engines for use in trucks and tractors, to state the most serious problems the engineers face in fulfilling the demands and how they have been met.

Truck and Tractor Engines—Part I

By H. L. Horning

Engineer and General Manager Waukesha Motor Co.

HISTORICALLY speaking, the prevalent truck engines of to-day are a development of the old type of passenger-car engine. It may be said with certainty that the engine for the light agricultural tractor, the demand for which has developed so rapidly in the last 2 years, is developing from our best types of truck motors.

It is the purpose of this paper, first to make a statement of the demands made on the modern truck and tractor engines; secondly, to state the most serious problems the engineer meets in fulfilling the demands and how they have been met; thirdly, what lines the development of the future likely will take.

Character of Service

For the purpose of clearly illustrating the differences in demand on engines a horsepower-speed diagram has been laid out illustrating the application of a 4 by 5¾-in. four-cylinder motor to a passenger car, a truck and a tractor. In each case the engine of these dimensions is assumed to be designed with the proper characteristics to handle the demands of the particular service.

An unbiased observer will admit that experiences have taught the all-around usefulness of four-cylinder motors in truck and tractor service, and wherever reference is made to an engine in this paper it will be considered a four-cylinder poppet valve engine.

Keeping in mind that a passenger car engine will turn over 20,000,000 revolutions in going 10,000 miles; a truck engine will turn over 60,000,000 revolutions in covering a distance of 14,000 miles, while a tractor during a period of 6 months will cause its engine to turn over 70,000,000 in plowing 600 acres with some road work and belt work.

Summing up, then, we may tabulate the results as follows:

The most interesting conclusion that can be drawn from the analysis of the above table is that, while the tractor demands of its engine in every respect more than a truck, nevertheless a well-built truck engine will meet the demands of tractor service, and in the interest of good engineering it must be said that a truck engine which will not stand tractor service is not an example of good internal combustion engineering.

Before passing on let it be understood that there are several important differences in the conditions under which truck and tractor engines operate, which are enumerated as follows:

(1) Trucks are stopped and started many times during a

TABLE I

	Average Road Speed	Motor Speed—Aver.	Motor Speed—Max.	Average Power Required	Season's Revolutions of Engine	Per Cent of Time Motor Is on Average Speed or Less	Per Cent of Time Motor Is on Maximum Speed
Pleasure car...	18 mi.	775	2,200	6½ Hp.	20,000,000	95	1
Truck	8-15 mi.	700	1,150	12½ Hp.	60,000,000	77	23
Tractor	2-3 mi.	1,100	1,100	22 Hp.	70,000,000	99½	100

day and operate with considerable variation in speed; in fact, sudden changes in speed and in power demands. A tractor demands a steady though heavy output from the engine at approximately governed speed, the variation being from 50 per cent to full load and overload. The steadiness of a tractor power demand is much more favorable to long life than the frequent changes of speed in the truck motor.

(2) A truck requires a maximum speed governor to keep the engine from the evils of racing and may be operated with profit with a maximum and constant speed governor combined. A tractor requires a constant speed governor to operate all the time.

(3) It is not essential to strain the dust out of the carbureter air in a truck or to pay particular attention to dust entering the breather, but it is absolutely necessary for long life of the tractor engine to see that every possible particle of dust be removed from the air before it enters the carbureter and great pains must be taken to see that no dust can enter through the breather. Two days of carelessness in these respects in some parts of the country will result in worn out rings, pistons, cylinders and bearings.

(4) Tractor engines should have flywheels with an average of double the stored energy of truck motors in order to satisfactorily meet the sudden peak loads of service.

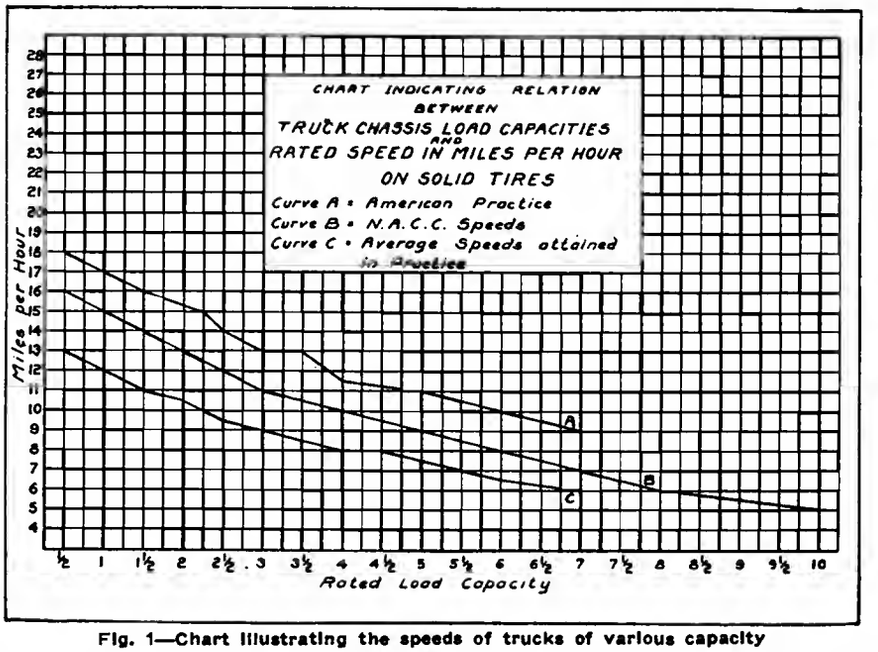


Fig. 1—Chart illustrating the speeds of trucks of various capacity

Statement of Commercial Requirements

Truck and tractor engines briefly stated are medium speed engines capable of producing a maximum torque continually at a minimum complete cost. Broadly speaking, they must fill some commercial service without undue thought, expense, trouble or care. Their true importance lies in the fact that they are the means to end and as such must be forgotten by the average user in pursuit of that end.

It is well in considering truck and tractor engines to keep foremost in mind that in the last analysis truck and tractor builders are selling transportation and it is the ability of the engine to deliver the torque, which through the mechanism of the truck or tractor, produces economical transportation that determines the engine's usefulness.

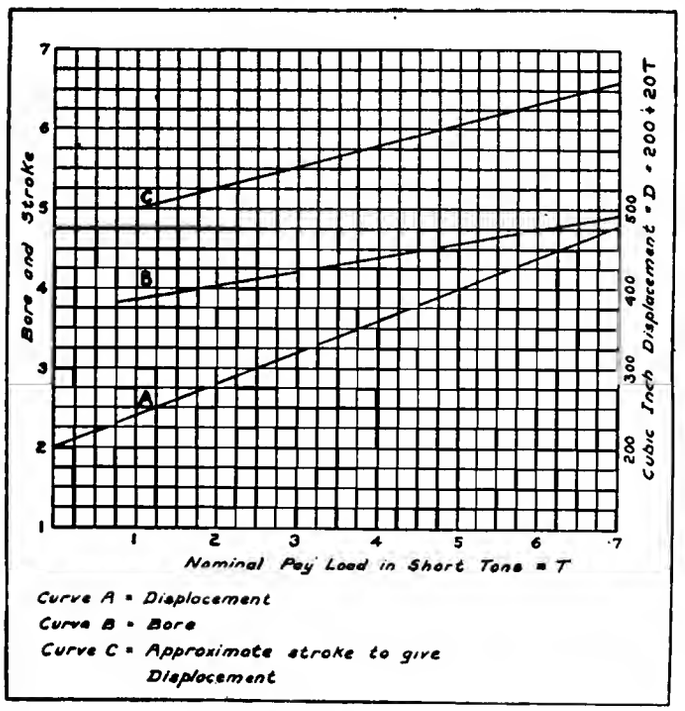

Fig. 2—Cubic inch displacement for various sizes of trucks

Engine speeds in American trucks are established by the practice of limiting piston speeds to 1000 ft. per min. Recent Government specifications of 1½- and 3-ton truck engines limit engine speeds to maximum of 1300 r.p.m. Truck speeds as established by the National Automobile Chamber of Commerce may be considered official, while maximum actual speeds are established by service conditions and are generally higher than the N. A. C. C. Average truck speeds (or miles traveled divided by hours taken) are generally much slower than the maximum.

Herewith appears a chart, Fig. 1, indicating the speeds of trucks of various capacity. The curve *A* represents maximum truck speeds as taken from the specifications of a large number of American truck makers. The curve *B* represents the maximum speeds adopted by the N. A. C. C., while the curve *C* represents an attempt at a speed representing the average speed at which trucks operate. The U. S. Government specifications for 1½-ton truck call for a maximum road speed of 14 m.p.h., while the 3-ton truck is specified at 12 m.p.h.

American practice calls for rear tire sizes as follows: 34-in. for ¾-ton; 36-in. for 1- to 3½-ton, inclusive; 40-in. for 4- to 7-ton, inclusive.

Having the engine speed, wheel diameter and maximum truck speed established, the matter of gear ratio reduces down to the most obvious one for general service and the engine size to one of ability. Starting with very large engines years ago the development seems to be toward higher engine speeds, smaller engines and lower gear ratios.

Piston displacement of American truck motors has been found to conform to the formula

$$D = 200 + (40\,T) \qquad (1)$$

in which D is piston displacement in cubic inches and T is nominal pay load in short tons.

Since an investigation of American truck engines indicates the ratio of bore to stroke as 1:1.3, therefore

$$D = 0.7854\ B^2 \times 1.30\ B \times N$$
$$D = 4.1\ B^3 \qquad (2)$$

Where B stands for bore of cylinder and N number of cylinders,

$$B = \sqrt[3]{\frac{200 + (40\,T)}{4.1}} \qquad (3)$$

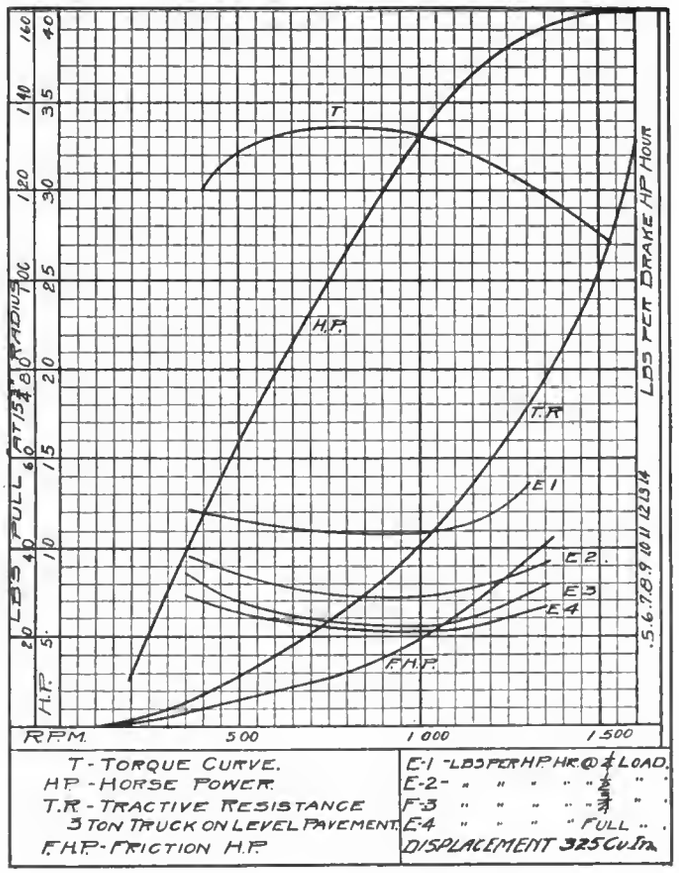

Fig. 3—Power curves of a well-known truck engine

Below will be found a chart, Fig. 2, which gives the cubic inch displacement for various sizes of trucks, also bore and stroke in which the ratio of 1.30 would give the proper displacement with the above formula.

It is important to call attention to the fact that many of our American trucks are assembled from standard units of which the engines and transmissions have been rapid adaptations from passenger-car practice. This, together with the inability to get correct worm-gear reduction to fit the engine and transmission combination, have produced gear ratios which do not fit the range of American or European requirements.

The transmissions are faulty in having a touring-car ratio between first and third, where a greater ratio is required for truck service. Some transmission builders are correcting this. Truck builders have been forced by inability to get a low first speed ratio to accept too low a ratio on third.

Conditions of service, manufacture and necessity of holding engine sizes down for sake of economy make it very desirable to have a gear ratio between first and third speed, three-speed transmissions, of at least 5 to 1.

Gear ratios are so important in the attainment of satisfactory service from the pulling standpoint and an economy in fuel that it may be well to pass to the consideration of engine characteristics as a fundamental consideration in determining gear ratios. This procedure has been too often neglected in the application of engines to truck service, principally, no doubt, from the fact that so many passenger-car engines have been used whose characteristics are not suitable for truck service.

Below will be found a diagram, Fig. 3, of a well-known truck motor. A study of this diagram shows that there are three speeds in the curves at which peaks occur, which are of vital interest, as follows:

(1) Speed of maximum torque, 783 r.p.m.

(2) Speed of maximum horsepower, 1450 r.p.m.

(3) Speed of maximum economy, 1044 r.p.m.

Obviously it would be ideal if all these speeds were identical and that the truck motor could operate at all times at the one best speed. This is impossible both because of correlative influence of each characteristic on others and because truck service calls for variable engine speeds. The engineer must, therefore, so apply his engine that each characteristic is available under running conditions.

The speed of maximum torque is established by combined influence of cylinder cooling, flame propagation, volumetric efficiency, carburetion, compression leakage and mechanical losses. At the speed of maximum torque the influence of cylinder walls in cooling the charge is on the decline, though it is never at its minimum. Turbulence of the charge and flame propagation is on the increase; volumetric efficiency is dropping; while carburetion is improving with speed.

Compression leakage is declining, while mechanical losses such as fluid friction of the lubricating oil, water and oil pumps, fans, etc., are absorbing power approximately according to a parabolic law.

At the speed of maximum torque, the highest M.E.P. figured from the brake horsepower is developed regardless of the cost.

The speed of maximum economy which always occurs above the speed of maximum torque is established through the combined influence of favorable carburetion, by the better atomizing of the nozzle, through increased flame propagation resultant from increased turbulence and good, though decreasing, volumetric efficiency. The time element as affecting the radiation losses, together with the decreased unfavorable influence of waterjacket temperature on economy and torque seems to combine for very favorable thermo-dynamic condition at the speed of maximum economy.

The above influences derive their value through the influence of motor design and assume a theoretically correct carbureter from the standpoint of furnishing the proper proportions of fuel to air. Of all the influences affecting economy, carbureter setting has the greatest actual effects. Of all the influences favoring torque and high speed of maximum horsepower, engine design has the most influence.

The speed of maximum horsepower is established by the favorable influence of violent turbulence and declining cylinder wall cooling effects, and by the declining volumetric efficiency and rapidly rising friction losses. It is impossible to consider here the full importance of these influences or to put forth the means adopted to compromise one characteristic with another—except to say that great torque per cubic inch displacement is seldom obtained with great economy without also sacrificing the smooth running of the engine over the range of speeds usually adopted on trucks.

In diagram Fig. 3 we find the speed of maximum torque at 783 r.p.m.; the speed of maximum economy 1044; speed of maximum horsepower, 1450 r.p.m. Using this motor for a 3-ton truck according to Fig. 1 and 36-in. wheel traveling 13 m.p.h., as per diagram, Fig. 2, with a gear ratio of 8.75-1, a common ratio with worm gear axle builders, we have a combination in which the governed speed is at the speed of maximum economy and the speed of average running 730 r.p.m.

Referring to curves for economy we note that as far as engine speeds are concerned we have chosen a good range for economical operation. This is only obtained by motors particularly designed for truck service. Passenger car motors of the four-cylinder type never have their torque or economy curves so favorably placed.

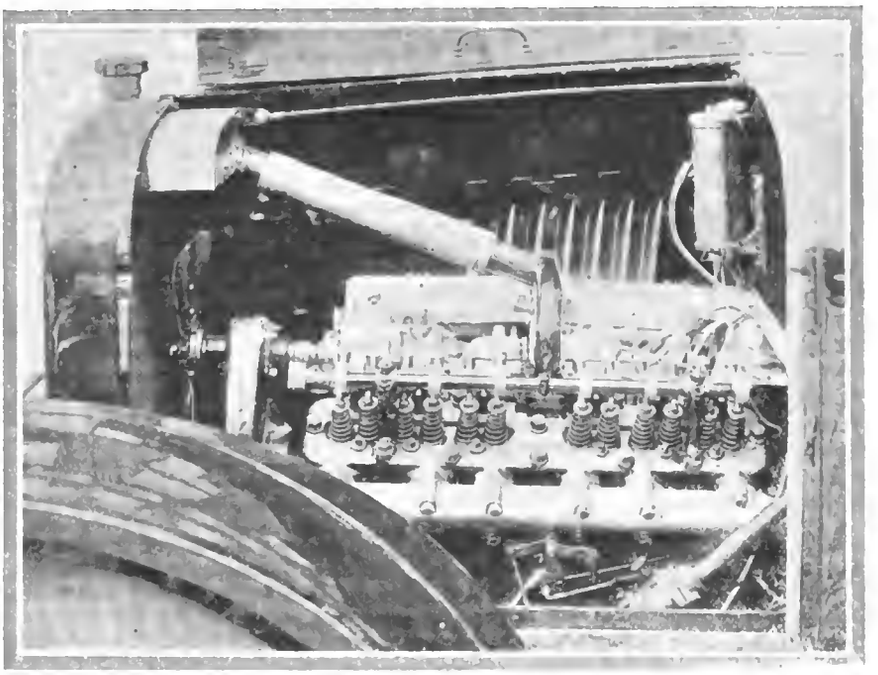
Referring to economy curves for one-fourth and one-half loads, we note a great difference in economy. It is this fact that makes trucks very uneconomical in fuel when equipped with over-sized motors and is the point on which eventually will be decided the question of higher motor speeds, smaller motors and higher gear ratios.

(*Continued on page* 411)

Enger Twelve Convertible to Six

Shifting Fuel Economizer Lever Cuts Off One Block of Cylinders Which Serves, However, as a Compensator for the Other

AN innovation in conventional automobile construction is found in the Enger Twin-Unit twelve for 1917, made by the Enger Motor Car Co., Cincinnati, Ohio. Through the shifting of a lever the Enger may be changed from a twelve to a six. This is the first time that such has been found possible in a stock car. The Schebler, one of the early twelve-cylinder experiments, used some such similar device, but no cars were ever marketed, only one having been built, as described in THE AUTOMOBILE for March 25, 1915.



Power plant of the Enger Twin-Unit twelve. The engine has a bore of 2⅜ in. and a stroke of 3½ in., giving a piston displacement of 186.04 cu. in.

Cutting Out Six Cylinders

The principle involved in changing the motor from a twelve to a six is extremely simple. A rod having six cams is placed over the push rods of the exhaust valves on the left block of the V and by throwing a lever placed on the steering post and under the wheel, this shaft with the cams is turned sufficiently to act upon the push rods and open the exhaust valves and hold them in an open position until the lever on the steering wheel is thrown back. At the same time the cams open the exhaust valves the turning action of the shaft carrying the cams closes a butterfly valve in the intake manifold to the left block. Thus the six cylinders are cut out, but they act as a compensator for the other six, which of course are off center.

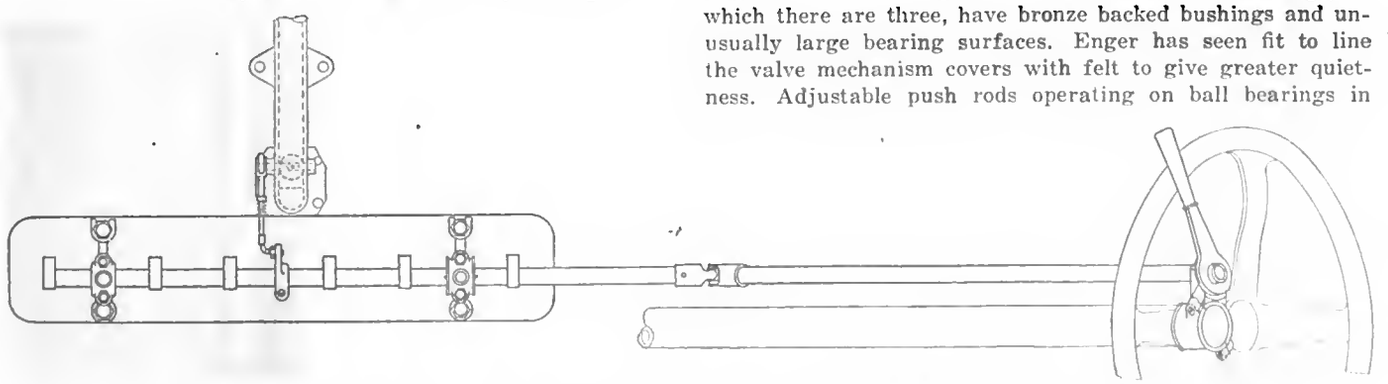
Displacement and Economy

The engine, which is of Enger's own construction, has a very small bore and stroke, being 2⅜ by 3½ in. This gives it a formula horsepower rating of 27.07, and a displacement of 186.04 cu. in. Enger's claim for great economy when the car is used as a six seems well taken since it stands to reason that with six cylinders having a total displacement of 93.02 cu. in., the engine may be more economical as to fuel than the car with a much larger displacement. The Enger has the smallest piston displacement of any twelve on the market to-day and from a flexibility standpoint it may be said that all speeds from a point where the speedometer rests at zero up to 60 m.p.h. are possible in high with the twelve cylinders in action.

A representative of THE AUTOMOBILE rode in the car over hills and on level stretches and found 40 miles per hour possible with the use of six cylinders and up to 60 with the twelve cylinders in action. On level ground starting was easy with the gearshift lever in high and under the same conditions, with the clutch in and the gears in high, a touch of the starter pedal was sufficient to start the engine and accelerate to 40 miles within a city block. There was no bucking of the engine when starting in high.

Valve-in-Head Engine

The engine is of the valve-in-the-head type and the cylinders are of semisteel. The main crankshaft bearings, of which there are three, have bronze backed bushings and unusually large bearing surfaces. Enger has seen fit to line the valve mechanism covers with felt to give greater quietness. Adjustable push rods operating on ball bearings in



Layout of economy device on Enger Twin-Unit twelve for 1917. The shaft has six cams that push the exhaust valves open. It is operated by a lever on the steering post. Turning the shaft also closes a butterfly valve in the intake manifold to the left block

ball socketed rocker arms with felt oil retainers also make for quietness. Three thousand revolutions a minute is the maximum engine speed and at this point it is said to develop 55 hp.

But one chassis is being built and this, a five-passenger touring type with streamline body and hood and double cowl, sells for $1,295. This is an increase of $200 over the previous twelve of last year, but the 1917 model is greatly improved in appearance over its predecessor. With a wheelbase of 116 in. and cantilever springs in the rear the car rides well. The rear axle is of the floating type with double row of ball bearings throughout and the drive is taken through spiral bevel gears.

A Stromberg carbureter placed in the V takes the fuel by gravity feed from the tank in the cowl, while the ignition is Remy and the electrical equipment two-unit Westinghouse. Lubrication is by pump, the oil being forced through the hollow crankshaft to the connecting-rod bearings. This pump is located at the bottom of the oil pan and it is in this pan that another departure from regular practice is found. Longitudinal tubes are cast in the lower half of the crankcase, which is the oil reservoir and the air rushing through these tubes help to keep the temperature of the oil lower. It also is contended that the oil passing into the cylinders not working is further cooled, since these cylinders are doubly cooled through the absence of explosion and the fact that the water from the radiator is not syphoned to that block as it becomes cold.

The clutch is a multiple disk, Raybestos lined and the housing is partially open to keep it cool. The clutch and gearset run on double annular ball bearings with the exception of the counter gears, which have bronze bearings. Two universals are used in the final drive.

Brakes are of the internal expanding and external contracting type. Tires are 32 by 4, non-skid in the rear.

The 1917 Enger is offered in two colors, a light cream and a black and green combination, the latter having the hood, fenders and chassis black and the body and wheels dark green. Other colors can be had at small additional cost. The upholstery is leather over curled hair and coil springs. The running boards and floorboards are linoleum covered and aluminum bound.

There is a remarkable absence of square corners in the Enger. The body rolls in a little at the top and the doors have a new design of fastener. When they are opened and the small lever pulled up sufficiently to allow the door to open, a spring-operated stud projects from the door toward the jam and holds the catch up. As the door is closed the jam strikes this stud, which releases the catch and it springs into place. The catches are set inside the door.

Equipment Is Complete

Equipment includes motor-driven horn, speedometer, robe rail, foot rest, one demountable rim and carrier, mohair one-man top and Jiffy curtains, rain vision ventilating windshield set on a slant, tools, etc. There is ample leg room both in front and rear compartments and the cushions are lower in the back than in the front to give better riding qualities.

150,000 Cars Registered by Texas Counties

AUSTIN, TEXAS, AUG. 30.—The Dallas *Morning News* has taken a census of the number of automobile licenses that had been issued in each county of the State during the period up to April 1, 1916. It shows a total of 139,013 licenses. It is estimated that since April 1 additional licenses have been issued which would make the total at this time approximately 150,000. The figures for each county were furnished by the county clerk. The census follows:

County	Cars	County	Cars	County	Cars	County	Cars	County	Cars

No Magic in Spring Design

All Types of Spring Can Give Equivalent Results—Semi-Elliptic, Cantilever, Etc., Suit Different Circumstances, But May Ride Equally Well

By A. Ludlow Clayden

THE idea that a spring had some special virtue *because* it was a cantilever or *because* it was a three-quarter type and so on, has been fairly well exploded. Apart from theory, experience teaches that taking any type of spring from the simplest to the most complicated, cars can be found using the same essentials and yet giving opposite impressions as to quality of suspension. There are, however, reasons for choosing different sorts of springs, and there are a few rules of a rough and ready order which apply throughout to spring design.

The mathematics of springs is a very complicated study to the average man. Mathematical experts usually claim that any given spring problem is perfectly simple, but engineers are apt to observe that the deductions of the theorists often disagree. The explanation is probably that in spring calculations it is necessary to make certain assumptions, and those assumptions are largely guesses. It is also noteworthy that engineers with really high scientific ability have usually been able to combine theory and experience and make cars with especially satisfactory suspension. Many engineers may lack the mathematical ability; many theorists certainly lack the practical experience.

Effect of Spring Type

To take a few of the debated points, one of the first is the effect of length of spring. Now, a semi-elliptic spring 60 in. long is roughly the equivalent of an elliptic 30 in. long or of a three-quarter with the two pieces 40 in. and 20 in. each, and it is equivalent for this reason. Suppose the maximum movement of the axle relative to the frame of the car is 6 in., this deflection is taken up throughout the length of the spring. A semi-elliptic 60 in. long will, when deflected 6 in., take a form like Fig. 1. An elliptic 30 in. long deflected 6 in. will bend as shown in Fig. 2. In the second case the total deflection is divided between the halves of the spring.

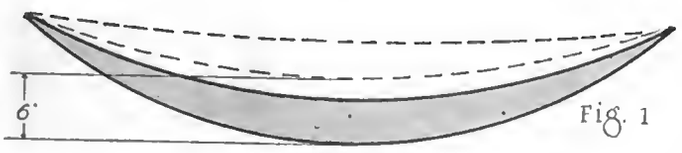

Fig. 1

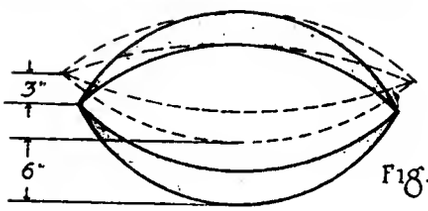

Fig. 2

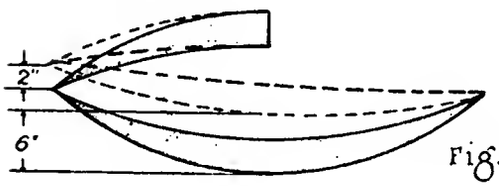

Fig. 3

Now take two points 10 in. apart on either the 60-in. semi-elliptic or the 30-in. half spring in Fig. 2, and it will be found that the relative displacement between the ends of the 10-in. section is the same in either case. In other words, each leaf is bent to the same extent by a 6-in. deflection whether the spring is a 60-in. semi-elliptic or a 30-in. full pattern.

This argument, of course, assumes that the upper and lower halves of the elliptic spring are the same strength. So with the three-quarter spring, it is necessary to proportion the strength of the 40-in. part and of the 20-in. part, so that the resistance to deflection is in proportion, we want, in the case of the three-quarter, two-thirds of the deflection to take place in the long portion and one-third in the short piece, Fig. 3.

This argument regarding length cannot be extended to cover the cantilever design, without some modification. That is to say the 60-in. semi-elliptic cannot be merely turned over and mounted as a cantilever without a change in detail and give the same effect.

In Fig. 4, suppose a weight of 100 lb. applied at *A* causes the frame to sink 1 in., then 50-lb. pressure on each end of the spring brings the frame 1 in. nearer the axle and the pressure required to cause this deflection may be regarded as 50 lb. on each end of the spring. Now take the cantilever in Fig. 5. Suppose the spring is just the same, then if we apply 100 lb. at the center it can be resisted by 50 lb. at each end as before. Under these circumstances the spring will be bent just as if it were a semi-elliptic, but the frame will have come 2 in. nearer the axle instead of 1 in., because point *B* is attached to the axle instead of to the frame. This is merely a matter of leverage. If we hang a weight from the middle of a bar we can lift it 1 in. by lifting *both* ends of the bar the same amount, but if we lift only one end of the bar we shall have to raise this 2 in. to obtain the 1 in. lift for the weight. This means that a cantilever spring which deflects, say, 1 in. for each 100 lb. of load on the car frame, would deflect only ½ in. if mounted as a semi-elliptic. This is only true in a rough way, as other considerations may affect the problem; it is merely to show what is the essential difference between the half-elliptic spring mounted either in the conventional way or as a cantilever.

Advantages of Long Springs

A long spring will obviously alter its curvature less for a given amount of deflection than a shorter spring, since the tangent to a large circle approaches more closely to the periphery than does a tangent to a small circle. This means that the metal of the long spring is less acutely bent or that the fiber stress is lower if the plates of the spring are the same thickness in both long and short springs. The life of a spring, or the time it will last before taking a permanent set depends upon the fiber stress; the smaller this is the longer the life will be. Thus a long spring is better for durability. Another reason for a long spring is that it causes less variation in the fore-and-aft movements of the rear axle relative to the frame.

With drive through the springs, which is almost universal practice to-day, and alteration in the curvature of the front

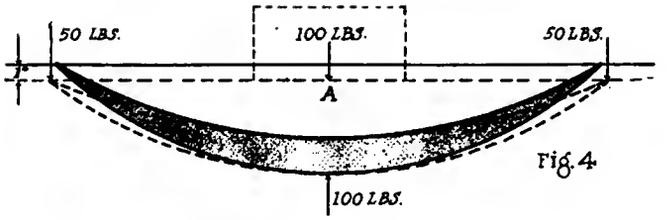

Fig. 4

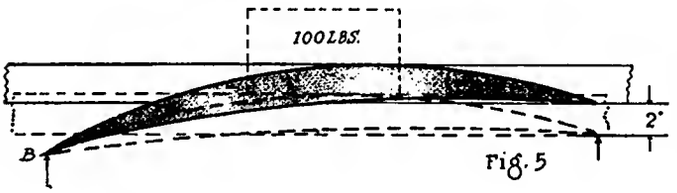

Fig. 5

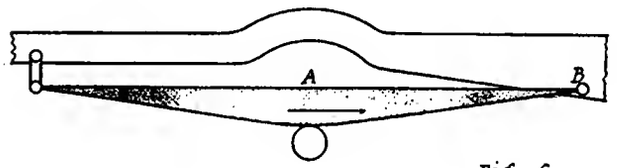

Fig. 6

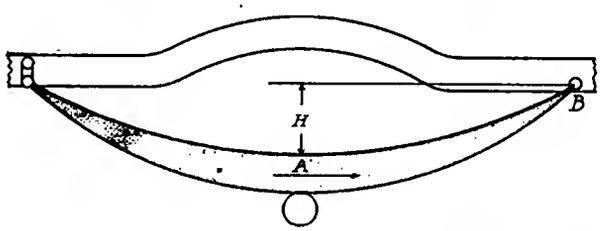

portion of the rear spring will pull the axle forward or push it back. The longer the spring and so the smaller the degree of bending caused by a given total deflection, the smaller will be the disturbance in the relationship of the axle to the propeller shaft and the smaller the work thrown upon the universal joints in consequence.

Effect of Flatness and Camber

Engineers frequently call attention to the fact when their cars have springs which are nearly flat with the normal load. This is an advantage for two reasons, one when the drive is taken through the springs, and another however the driving effort is accommodated. Regarding the driving effort, consider the two springs shown in Fig. 6. The axle *A* applies a push to the middle of the spring which the latter transmits to the frame. If the point of attachment of the spring to the frame is normally in line with the middle point (if *A* and *B* are both on the same horizontal line), the drive has no tendency to distort the spring, but if the spring is curved so that there is a vertical distance *H* between the horizontal planes of *A* and *B*, then the force of the drive tends to increase the curvature of the spring, since the point *A* has a leverage *H* over the point *B*. Obviously this means that a flat spring does not have its "springiness" affected by the additional duty of taking the drive, while the curved spring must have extra strength to resist the bending tendency of the drive; over and above the strength required for supporting the weight of the car.

Next, a flat spring of the semi-elliptic type is better able to resist side stresses, and so is less liable to allow the body to roll on taking a curve at speed. This is explained by Fig. 7, which supposes a side stress equal to *x* lb. is acting at the spring eyes, then it is resisted entirely by the top plate of the spring which it tries to bend in the direction of its width; the opposite to the way spring action bends it. Obviously it has enormous strength to resist such bending. Now imagine the spring has a camber *h* so that the middle of the top plate is *h* in. below the spring eyes; then the side stress has a twisting leverage *h* over the middle point of the top plate. In other words, the side stress tends to twist the spring instead of merely trying to bend it laterally. That the spring is much more able to resist the bending than the twisting action is obvious. Of course, this is considering only side pressure and is not a complete analysis of the forces acting, but it suffices to show why a flat spring is stiffer sideways than a curved one.

This is a good place to mention width of spring and its effect, for from the argument above it is at once appreciated that the lateral stiffness of a spring with wide leaves is greater than that of one with narrow ones.

In considering driving stresses and torque reactions as well as in regard to sideways stiffness, it is the top plate of the spring that is most important. The other plates merely support the top plate from beneath. For example, in the case of driving through the springs, suppose the top leaf was too thin; then the push applied by the axle could cause the top plate to buckle and the other plates would have no power to prevent it. Every force passing between the axle and the frame of the car must go *via* the spring eyes and so *via* the ends of the top plate, which is why the top plate cannot be less than a certain thickness, however thin the other plates may be.

Effect of Number of Leaves

The reason for the multiple leaves in a spring is to provide friction to damp the free movement or bounce of a spring. We could carry a car on coil springs or on springs with but one leaf, but such springs would be too lively for actual use. Now we can make a spring of a given strength from a few thick leaves or from many thin ones; some springs in use on automobiles have as few as seven leaves and some as many as thirty-two. If a spring consisting of one leaf is compressed and then released it will oscillate till the molecular friction within the steel brings it to rest again, just as the friction on the pivot of a pendulum will stop its swinging after some lapse of time. If the spring consists of two leaves there will be less molecular friction within the steel, but friction will occur between the plates each time the spring is flexed, it is as though the pendulum in swinging was touching something lightly. The amount of friction is not directly proportional to the number of leaves, of course, but it increases as the number is raised.

The action can be regarded another way. Suppose the spring is such that a load of 100 lb. will compress it 1 in., if the load is applied instantly a spring with no friction will compress instantly. By virtue of this compression the load applied acquires kinetic energy which carries the spring beyond the 1-in. compression, the spring then rebounds and the action continues indefinitely. If the spring has several plates so that there is frictional resistance to flexion, but is still of the same strength so that 100 lb. will compress it 1 in., the kinetic energy of the movement during the compressing action is absorbed by the friction. If the friction is enough the kinetic energy will be absorbed entirely during 1 in. of movement so that there is no rebound till the load is removed; such a spring is said to be "dead beat" in scientific jargon.

Reaction when the load is removed has just the same effect on the spring as does the application of the load, so a multi-leaf spring which is dead beat, or partially so, on compression, is also dead beat on rebound.

There is another beneficial action due to the use of a large number of thin leaves, and this is that the life of the spring is increased. A flexible cable made up of many strands of wire can be bent tens of thousands of times, perhaps, while a single solid wire of equal strength might not

be bendable at all without breaking. So with the spring leaves, the length of the spring determines the arc to which it will be curved by a load put upon it. In Fig. 8 two pieces of material are shown bent to the same curve, with an outer radius R and an inner radius r. The normal length of each plate when flat is equal to the length of the bent plate measuring along the center line of the plate, otherwise along the arc midway between R and r marked S in the sketch. This is equivalent to taking the straight strip and pulling out the top while compressing the under part as shown in Fig. 8. The normal length is L, the length of the top when pulled out or bent is $L + x$ and the length of the underside $L - x$, we have, by bending the plate stretched half of it x in and compressed half of it x in. Now with the thin plate the difference between R and r is much less. If the thin plate has a normal length L as before its upper and lower sides when bent will be $L + y$, and $L - y$, and y is obviously much smaller than x, meaning that the material is much less strained in the thin plate than in the thick one by being bent to the same arc of a circle. This means that the thin leaf spring will take much longer to "tire" than the thick leaf, that it will retain its strength longer, other things being equal.

The limitations in making thin leaf springs are mechanical. Firstly, as explained before, the top plate must be thick for reasons unconnected with its spring action. Also the thin leaves are more troublesome to make than the thick ones, as they cool more rapidly between the time they are taken from the furnace and the time they are bent and plunged in oil to cool. This process is conducted very accurately, but it is only possible commercially to handle leaves of appreciable thickness. One could not, for example, make a motor car spring with 100 leaves, though about a third of this number is possible.

Another drawback is that a multi-leaf spring of a given strength is heavier than one with few leaves. Because the metal is less severely strained by bending, ten thin leaves of equal weight to five thick ones will not make as stiff a spring. The extra weight and the extra number of operations in making a thin-leaf spring cause it to be more expensive than a spring with thick leaves. At present the thin-leaf type is only a little more than experimental. Springs with thirteen or fourteen leaves are not unusual for heavy cars, but whether twenty or thirty leaves will become common cannot be decided yet.

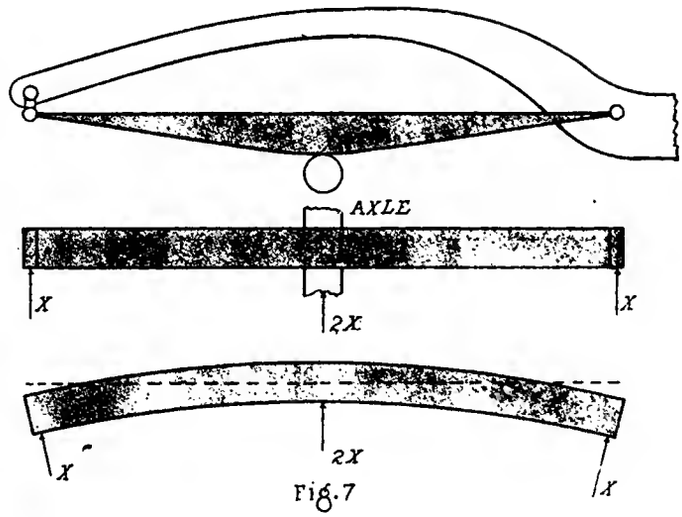

Fig. 7

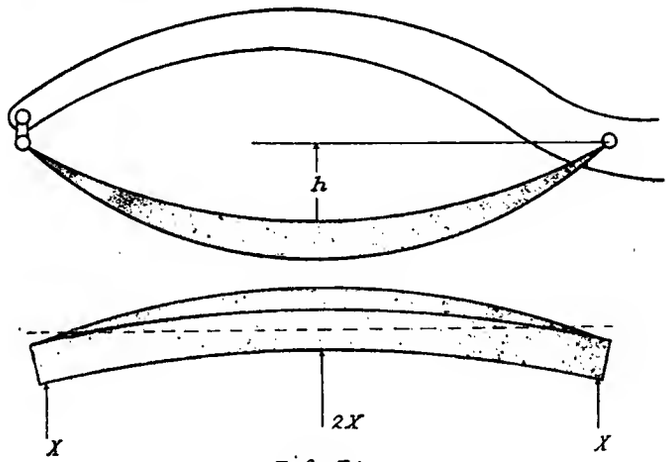

Fig. 7A

Why Axle Weight Is Important

Despite many arguments in the past, it is now generally agreed that a small unsprung weight improves the spring action of a car if everything else is unchanged. This can be explained by following along the line of argument used in connection with the effect of many leaves. Suppose the axle is lifted by a bump in the road a distance of 6 in., the ideal spring will absorb all the force of the blow and will not allow the body of the car to be raised at all. Now, if the spring has a strength of resistance equal to 100 lb. per inch of compression, a force of 400 lb. is necessary to compress it 6 in. Now, 6 in. is half a foot, so that the amount of work put into the spring by the lifting of the axle is 200 ft. lb. If the bump is merely a ridge leading up to a higher level on the road, the 200 ft. lb. will be partly absorbed by friction in the spring and partly used up by slowly lifting the body of the car till its distance from the axle has become normal again.

Now, if the bump is followed by a drop, as usually happens, no part of the 200 ft. lb. should be absorbed by lifting the body of the car, instead it must be used up completely. The compressed spring, when the wheel is at the top of the bump, contains 200 ft. lb. of energy which must be dissipated somehow, and the only way to absorb it is to use it up in friction within the spring or in some shock-absorbing device.

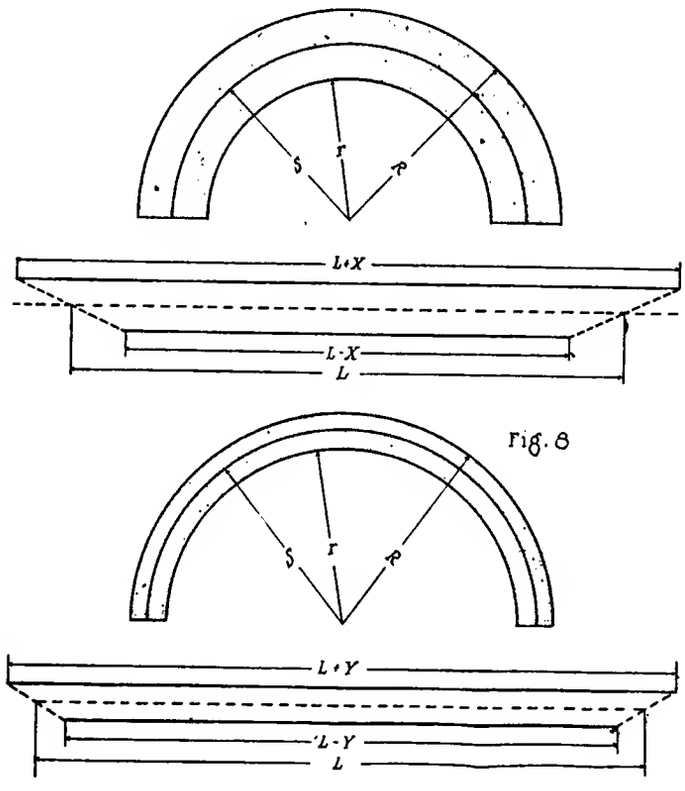

Fig. 8

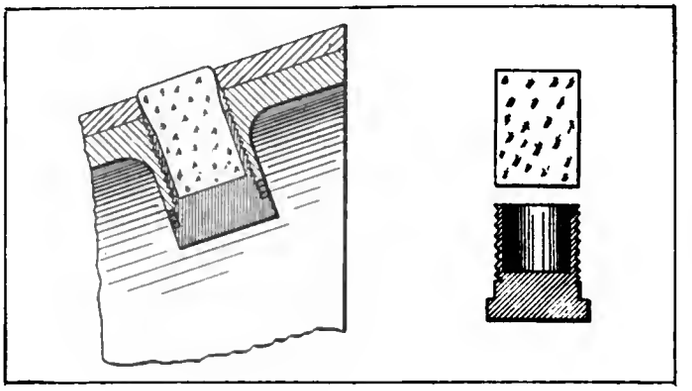
(This, like several other illustrations chosen, is not strictly true scientifically, but the error does not affect the point which it is desired to bring out.)

So far, an amount of energy equal to 200 ft. lb. has been considered because this is the amount of work necessary to compress a 100-lb.-per-inch spring a distance of 6 in., but actually the amount of energy put into the spring is greater than this. In rising up the 6-in. bump, the weight of the axle has been raised half a foot, so, if the axle weighs 200 lb., an amount of work has been done equal to 100 ft. lb. This does not affect the spring, but something which arises from it does. In running up the bump the axle acquires an upward velocity, and, if the bump is very sharp, the kinetic energy stored up in the axle by the time it reaches the top will be sufficient to make the tire leave the ground. In order to prevent the wheel from lifting, the spring must absorb the kinetic energy of the axle in addition to absorbing the 200 ft. lb. due to its own compression. Kinetic energy is a product of mass and velocity, so if the bump is the same size and the speed of lifting the same, a heavy axle will have more energy stored in it on reaching the top of the bump than will a lighter axle. Since this energy has to be absorbed by the spring it will be apparent that the spring has less work to do when the axle is light than when the axle is heavy.

Device for Increasing Security in Shipping Cars

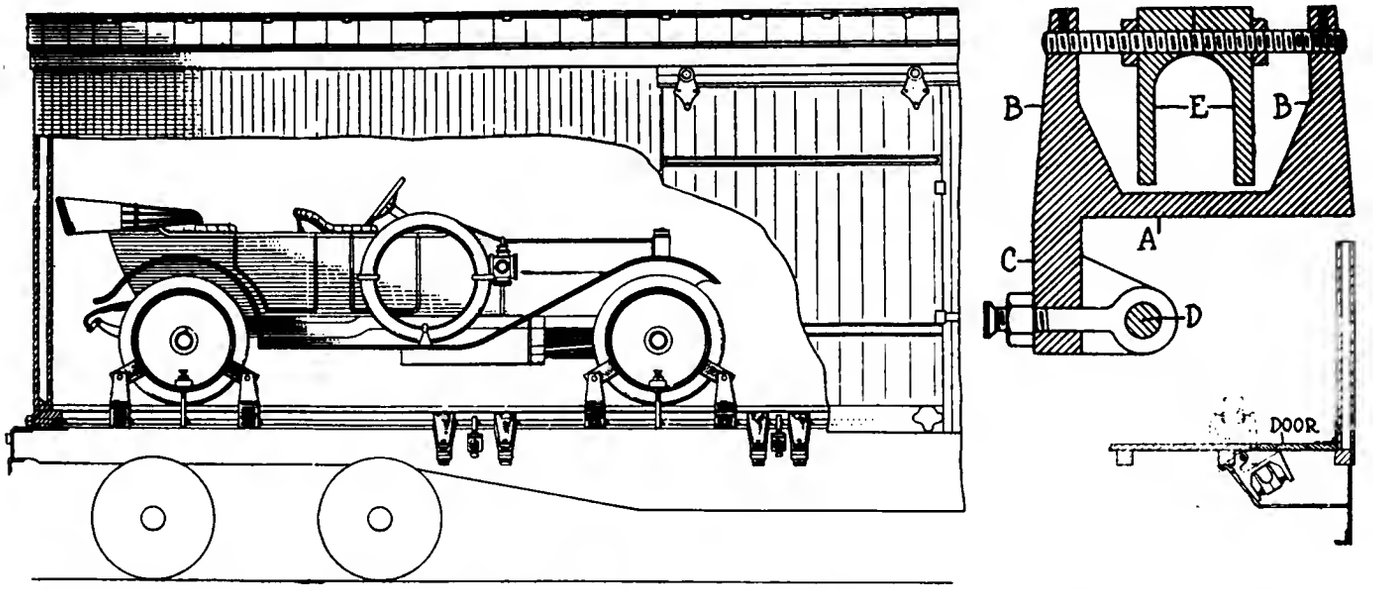
AN interesting device for securing an automobile during shipment in a freight car has been invented by E. F. Martin of New Orleans, La., patent No. 1,102,773. The attachment is fitted in the automobile freight car and is designed to prevent the car from movement either longitudinally or laterally in the freight car and also to prevent any undue wear of the tires or dents in the rims while in transit. The mechanism is also so arranged that it can be moved out of operative position below the floor of the car to prevent interference with other freight when it is carried.

The freight car is provided at each side of the floor with a longitudinally extending opening and these openings are normally closed by a series of doors which swing upward against the inner face of the side of the car or downwardly against the floor. These doors are closed under normal conditions and when they are closed the car does not differ from the ordinary freight car and may be used for other purposes than for automobiles. The supporting and clamping mechanisms for the four wheels of the automobile are connected with a rod which is located lengthwise in the car and held in fixed position. The supporting mechanism swing about these rods and when raised into position to hold an automobile each one comprises a substantial U-shaped support consisting of a body *A* with arms *B* and a lug *C* which hold the members supported to the rod *D*. In addition there is a U-shaped part *E* which swings upward and around the tire holding it firmly in position.



Slade Devises Adjustable Clutch Inserts

The invention illustrated above has recently been patented by Marshall P. Slade, Mount Kisco, N. Y., its idea being to provide a cork cushion for a cone clutch in which the corks can be renewed easily. Each cork is mounted in a sheet metal "cartridge" which can be screwed into place from the inner side of the cone. Shims can also be provided in the form of washers to allow the cork to be adjusted without renewal. The advantages of such a device as this are manifest, from the standpoint of both economy and convenience.



Martin device for adding to the security of automobiles in shipment on freight cars. This clamps the wheels and holds the car against stress in any direction

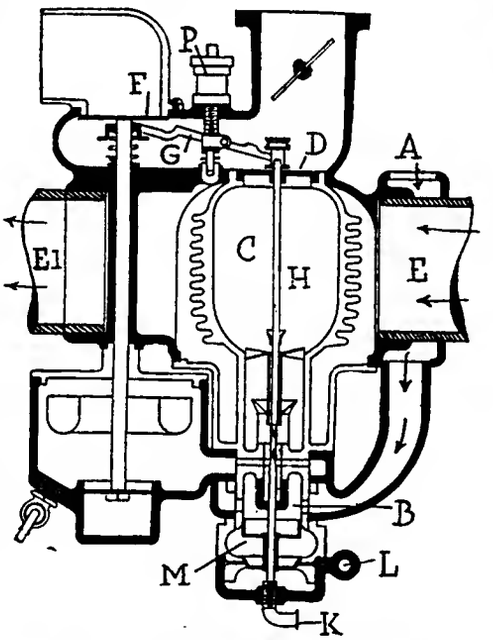
Kerosene Standard Tractor Fuel

Bennett Carbureter One of the Most Successful in Use and Fitted to Many Tractors—Design Based Upon Correct Principles

THE AUTOMOBILE for March 30, 1916, contained an article in which the major difficulties in carbureting kerosene were described, and it was pointed out how the various requirements for proper vaporization conflicted, making the design of a carbureter vastly more difficult than that for a gasoline instrument. One of the difficulties which have been among the troublesome ones is that more heat is required for vaporizing when running the engine at low throttle than running at full power. This means that when we have the greatest amount of exhaust heat available we want least, and vice versa.

Heat at Two Places

The Bennett carbureter, made by the Wilcox-Bennett Carbureter Co., Minneapolis, Minn., is now being used on a great number of tractors as standard equipment, and this instrument is constructed to take care of the peculiar heat requirements of kerosene. Briefly, heat is applied at two places. The main air has a variable temperature, decreasing as the load increases. The sprayed kerosene, mixed with the main air, then passes through a chamber which is kept at a fairly constant, high temperature by the exhaust, and after this cold air is added in quantities depending upon the suction prevailing at the moment.



Section through the Bennett carbureter, which is designed for the use of gasoline, kerosene, alcohol and distillates

Referring to the sectional drawing, the air enters at *A*, passes around the pipe *E*, which is the outlet for part of the exhaust of the engine, and gets beneath the nozzle through the holes *B*. Then the air passes upward through vertical holes around the jet and up into the chamber *C*. This chamber is surrounded by the exhaust gas entering at *E* and passing out at *E*1. *D* is not a valve, but merely a bridge piece, so the air mixed with the sprayed kerosene goes from *C* directly to the throttle.

As soon as the suction increases, as when the throttle is opened, the flat valve *F* begins to lift. This operates the lever *G* and raises the spindle *H*, thereby enlarging the kerosene nozzle, which is adjustable for permanent setting by the threaded needle valve *K*.

A Dashpot Feature

Now, right at the bottom of the carbureter there is a small hole *L* which lets in air under the little double piston *M*, and when the suction is strong enough, the double piston lifts and so closes the holes *B*. When the piston has risen high enough to close the holes *B* the hot air is cut off altogether by the rim of the upper part of the piston, but enough cold air to spray the fuel enters through *L* and gets to the nozzle through holes in the head of the upper part of the double piston. It will be noticed that the air valve *F* has its stem carried down into a kerosene well at the bottom of the float chamber, this acting as a dashpot. Also adjustment of the amount of expansion of the fuel jet in proportion to the air valve lift can be made by the screw *P*.

The effect of these different mechanisms is that, at low speeds, the hot air starts the vaporization of the kerosene, which is completed by contact of the mixture with the hot walls of the chamber *C*. When the engine is running hard, the chamber would get so hot that cracking might occur, therefore the hot air supply is cut off to allow the original mixture to enter *C* while cold. Actually in normal working it is stated that the gas leaves the carbureter at the throttle at 230 deg. Fahr. when idling and at 110 deg. Fahr. when at full load.

Automobile Possibilities

So far this carbureter has not been applied to automobile work, but exclusively to tractors, where it is in use on engines with two and four cylinders. Of course, the idling speed of a tractor engine is higher than that of an automobile motor, and the maximum speed is much lower, which means that the range is smaller, but the principles of the Bennett carbureter seem so closely in accord with theory that it should not be difficult to design a modification which would suit automobiles.

For starting purposes gasoline is fed to the carbureter instead of kerosene, a small tank of the lighter grade fuel being carried for this purpose. With most engines a few minutes running heats the vaporizing chamber sufficiently to allow a change over to be made to kerosene.

Kerosene Increases Heat

Mr. Bennett states that he finds the power of the kerosene explosion is sufficiently greater than that of gasoline to make it advisable to use a compression for kerosene rather lower than would be right for gasoline. The compression ratios to give definite explosion temperatures and pressures with gasoline are fairly well known, and kerosene needs a little less compression to keep the explosion pressure the same as with gasoline. The effect of introducing a small quantity of water with the gas is equivalent to reducing the compression, as the steam which is formed on explosion abstracts some heat from the charge and so lowers the maximum pressure at ignition.

In operation on tractor engines the Bennett carbureter gives full flexibility and there seems to be no smoke at low speeds, the engine idling just as well, when warm, on kerosene as on gasoline. On opening the throttle there is no hesitation or choking, the engine gets away without any symptom to show that the fuel is of heavy grade.

New Eight To Lead Jackson Line

48-Hp. Valve-in-Head Engine in Chassis Offered with Four Body Styles—Other Three Models Continued

THE new eight announced in THE AUTOMOBILE for Aug. 31, with a 48-hp. valve-in-head Ferro engine, and supplied in four attractive open-body styles will lead the Jackson line for next year. Outside of the change in power plant, the car is characteristic, and has the well-known full elliptic springs. The wheelbase is 118 in., and tires are 34 by 4 non-skid rear.

The three present models, two eights and a four, will be continued without change.

The price of the new model is in between that of the other two eights. It sells for $1,295 as a two or five-passenger. The four-passenger is $1,395, and the seven-passenger $1,370.

These figures are slightly higher than the five-passenger eight, which is continued at $1,195, and considerably below the seven-passenger eight at $1,685. The four-cylinder model lists at $985.

The bodies for the new chassis are decidedly modern and are attractively painted, the color combination being light maroon with black running gear and fenders.

Wire Wheels on Four-Passenger

All have tilted windshields, five and seven-passenger cars have a double cowl and the body rim is rolled in. Divided front seats and a sloping deck characterize the four-passenger, which has wire wheels as standard equipment.

The chassis is built of standard parts and the design is mainly conventional. The motor is combined with a Borg & Beck plate clutch and a three-speed Covert gearbox. The clutch is a departure in Jackson construction in that the other models have leather-faced cones.

The motor is a 3 by 3½ in. and develops its maximum of 48 hp. at 2400 r.p.m. The formula rating is 29 hp. and the piston displacement is 198 cu. in., which gives 0.246 hp. per cu. in. of piston displacement.

Intake Manifold and Water Outlet Combined

Both blocks of cylinders and the upper half of the crankcase are cast in one piece and the cylinder heads are detachable. Intake manifold and water outlet header are combined, the latter forming a jacket around the former; this not only gives a simpler construction, but also provides heat for the mixture. The manifold is arched and the carbureter is suspended from the center. Condensation cannot settle in the manifold but must run to one cylinder block or the other, thus loading is prevented. The generator is placed at the front of the V, and the ignition distributer at the rear. The exhaust pipes are on the outside.

Generator Is Belt-Driven

A feature of the design is that, although the valve-in-head construction is used, the valves are completely inclosed, yet they may be adjusted or the rockers may be oiled without removing the covers. This is due to the peculiar valve construction. The rocker is a steel pressing and has a cup at its center which fits over a ball-ended stud mounted in the head, which is adjustable from the outside, and by moving it in or out, the proper clearance between the rocker and the valve may be obtained. The ball joint is oiled by a wick which is placed in a hole drilled in the center of the stud.

Carbureter is a Zenith duplex, to which gas is delivered by the Stewart vacuum system. Starting and lighting are supplied by Auto-Lite units and ignition is by Remy distributer. The generator is driven by a 2-in. flat belt from a pulley on the crankshaft and adjustment is obtained by raising the hinged platform which carries the generator.

A two-blade fan is mounted on the front end of the generator shaft, and cooling is by thermo-syphon in conjunction with a vertical tubular radiator.

The crankshaft has three main bearings of 1 9/16 in. diameter, the lengths varying from 2¼ to 3 in., and connecting rod bearings are 1 9/16 in. diameter. The forked type of connecting-rod is used. The wristpins are bronze bushed.

Pistons are cast iron and have three Wasson rings. The pistons are slightly relieved on the wristpin sides. The wristpins are held in place by a setscrew and cotter pin. The clearance between piston and cylinder is 0.003 in.

The camshaft carries an independent cam for each valve and is mounted on three bronze bearings. It is driven by helical gear, and roller valve lifters are used. Valves have a mean diameter of 1⅜ in. with a total lift of 0.326 in.

Pressure and Splash Oiling

Lubrication is combined pressure and splash feed. The crankshaft and connecting-rod bearings are pressure fed. The gear oil pump mounted at the front of the motor pumps the oil through a regulator and thence through the hollow crankshaft to all the bearings. The suction line of the pump is on the right side of the motor and feeds the oil through a screen in the bottom of the pan directly to the pump.

The pipe line on the left side of the front engine gear cover leading to the oil regulator is the main oil pressure line. In order to prevent excessive pressure in the system a relief valve is interconnected with this line, which starts to open at a comparatively low pressure and throws the oil on the engine gears. This valve is placed on the top of the gear cover, and in case the oil gage does not register it may be found that dirt is interfering with its operation.

Hyatt roller-bearings are used throughout the gearbox. The shifting lever is a ball and socket type mounted in the gearcase cover. Carried on one side of the gearcase is a single-cylinder Stewart air-pump which may be thrown in action by a lever in a pocket in the floorboards. This pocket also carries the air-holes.

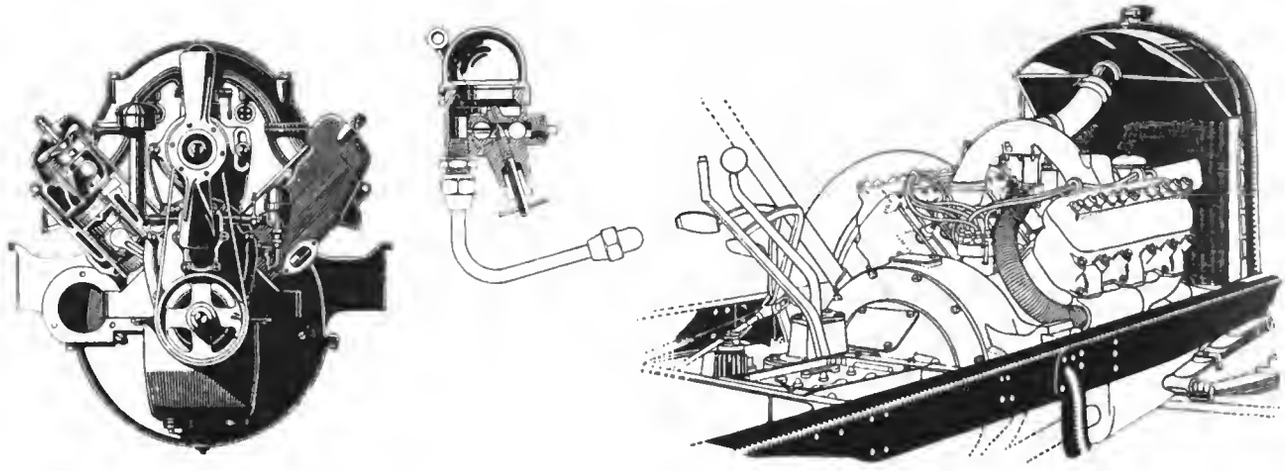
The driveshaft has two universals and both torque and driving strains are transmitted through the springs.

The rear axle is a Salisbury floating design with spiral bevel drive giving a 4¾ to 1 ratio. Brakes are internal and external 12 by 2 in. Bearings are Hyatt, New Departure and Gurney. The front axle is an I-beam made by the same concern.

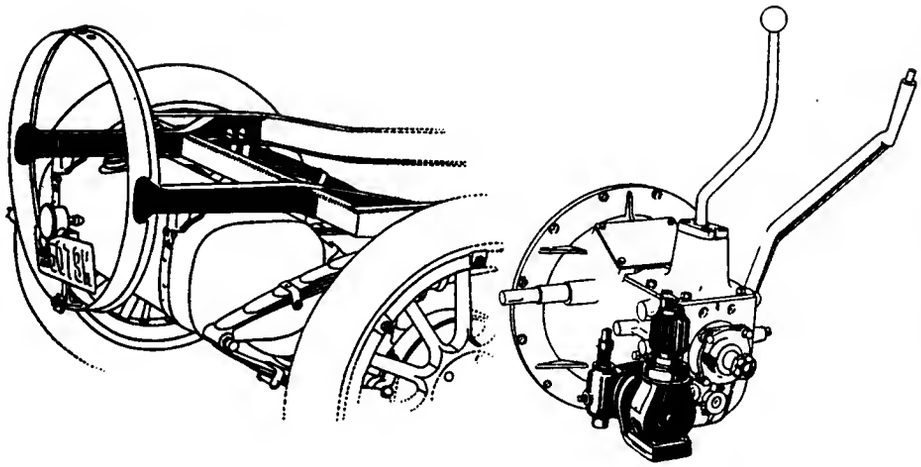
New Tire and Tank Support

A new support for the spare rim and gasoline tank has been devised. It consists of two horizontal channel members overhanging the rear cross member. The tank is suspended from these and the rim carrier is bolted to their ends. They are solidly anchored in the frame, extending forward to form diagonal reinforcing or gusset members for the frame.

A new door-lock has been designed which is extremely easy to operate under all conditions and yet is simple in construc-



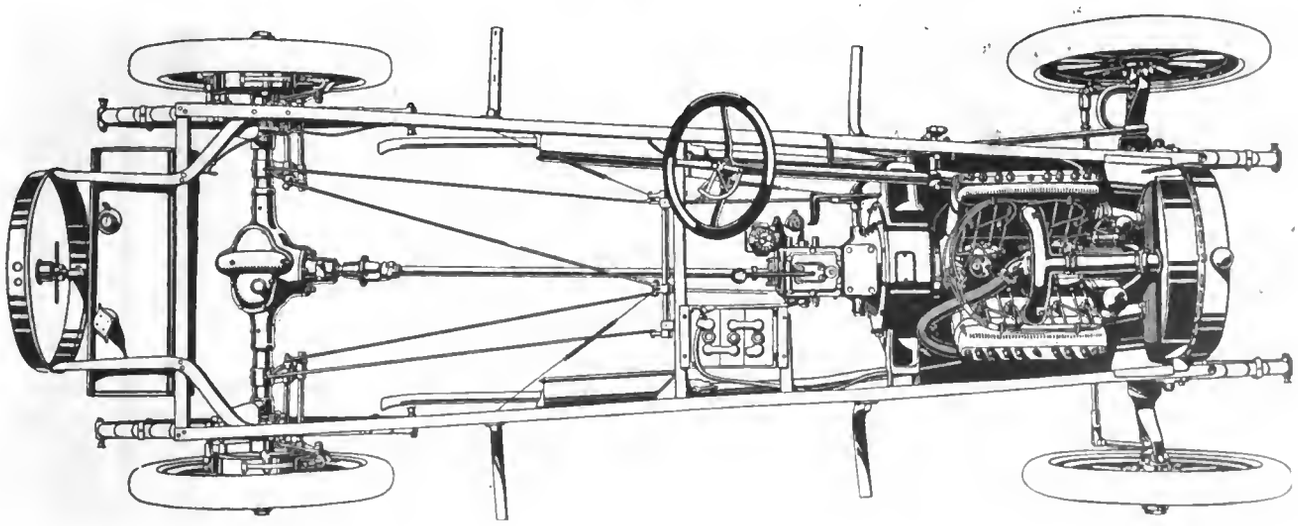
Details of the New Jackson Eight

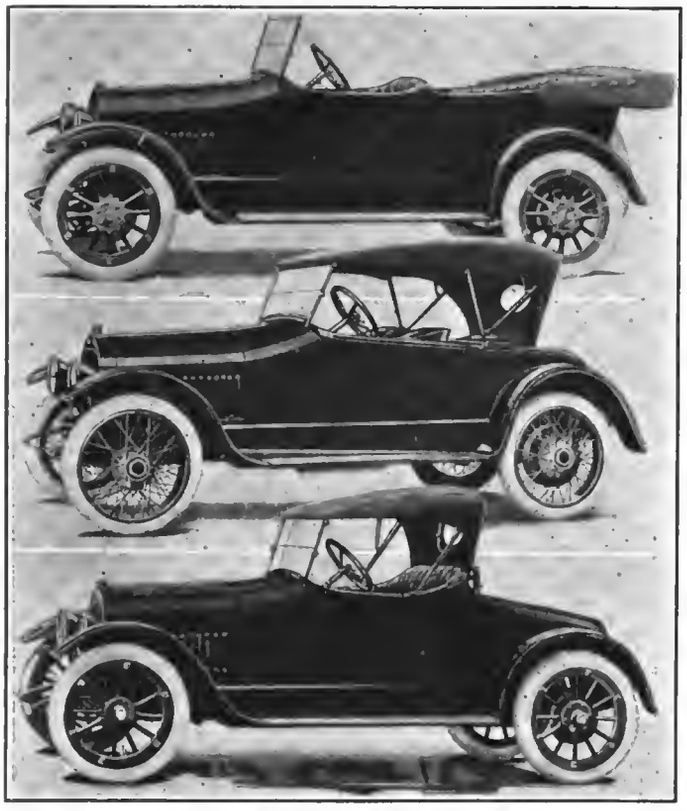


ABOVE at the left is the engine with the right block in section. Note the oil regulator with needle valve control mounted in front of the left block. This is illustrated in detail in the center. At the right the olean design of the power plant is brought out. The cylinder heads are detachable and the intake manifold and water outlet header are combined.

At the left are illustrated the substantial rear construction, tire carrier, fuel tank, etc., with the power tire pump mounting immediately to the right.

Below is the chassis in plan view, showing taper frame, compact power plant and mounting of storage battery.





Upper—Touring body on the new Jackson eight chassis selling at $1,295. Middle—The four-passenger cloverleaf at $1,395. Lower—Two-passenger roadster at $1,295. All have tilted windshields and rolled-in body rim. Wire wheels are fitted as standard equipment on the four-passenger

tion. It is operated by a button which is flush with the upholstery and consequently cannot catch the clothing of passengers getting in or out. An advantage is that pushing the button and opening the door is one movement, and it takes very little pressure to operate the button. The catch on the lock rotates instead of sliding, as is usually the case. It is pinned to a short rod and the position of these two members is such that they are just over dead center and the catch cannot be moved. When the button is pressed these two members are thrown off dead center and the catch opens.

The four-cylinder car known as model 34A is made as a five-passenger touring or two-passenger roadster. It has a unit power plant consisting of a 3½ by 5-in. L-head block engine, cone clutch and three-speed gearbox.

Schebler carbureter and Stewart vacuum system are used; ignition is supplied by a Connecticut distributer and starting and lighting are Auto-Lite units. A centrifugal pump is used for circulating the cooling water. The wheelbase is 112 in. and tires are 32 by 4, with non-skids in the rear.

The smallest eight is also made with a two or five-passenger body and the largest eight with a seven-passenger body. The former has a 2⅞ by 4½-in. engine and the latter 3½ x 4½-in. The specifications are the same as for the four except that the largest eight has 124-in. wheelbase and 34 by 4½ tires.

The stock color for the four is Brewster green with black-enameled hood and fenders. The smallest eight is dark green and the largest eight dark blue, both with black enameled hood and fenders.

The equipment is complete, consisting of one-man top, Collins curtains, with curtain openers on the doors, rain-vision windshield, Stewart speedometer driven from the transmission shaft, etc. All three eights are equipped with a tire-pump and the four is designed so that a pump may readily be attached.

Red Cross Truck for New York Militia

CAPABLE of traveling 72 hr. in a desert without replenishing its supply of gasoline, oil or water the special 2-ton Jeffery Quad shown in the illustration was recently presented to the New York National Guard by Mrs. Cornelius Vanderbilt of the American Red Cross Society. The vehicle has been shipped to the Mexican border by express, together with six Trailmobiles, each of which is fitted with stretchers to accommodate four wounded men. The vehicle will be manned by two drivers, six nurses and two doctors. The cruising radius of the outfit will be more than 400 miles, the additional gasoline necessary being taken along in steel barrels slung from the body platform on both sides of the truck, as illustrated. In all, 134 gal. of gasoline, 20 gal. of lubricating oil and 300 gal. of fresh water are carried.

Eynon Heavy-Fuel Carbureter Uses Electric Heat

No More Parts Than in the Conventional Gasoline Type of Instrument—Complete Gasification Claimed Even with Alcohol or Heavy Distillates

ALTHOUGH gasoline prices are lower now than they have been in some time, there is no lull in the activities of inventors all over the country who are working on a feasible scheme for burning the heavier grades of fuel in automobile engines. In all of the carbureters intended for this purpose, now coming through, there are two tendencies which are distinctly observable. These are the positive preheating of fuel and air, and a well-defined means of breaking up the fuel into globules.

Electric Heating a Feature

One of the latest of these, the Eynon carbureter, to be made hy the Kerosene Carbureter Co., Cleveland, Ohio., exhibits both these tendencies to a remarkable degree. The heating feature is particularly interesting because it is electric. This is not the first time that electricity has heen applied to the vaporizing medium, but it is one of the first attempts to make the electrical feature a unit part of the carbureter itself and to be a factor in producing the explosive mixture. The use of electric heating is, of course, due to the fact that it is independent of the engine. Where the engine is started on gasoline and then operated on kerosene, the exhaust heat is naturally available.

In starting on the heavier fuel, as is intended to be done with this instrument, electric heat is immediately available. It is simple, and since the passages to be heated are small, only an unimportant amount of current need be consumed. The total number of parts in the Eynon carbureter number about fifty, or about the same as in the ordinary gasoline instrument.

The electrical device consists of an ordinary spark splug inserted in the upper part of the mixing chamber and attached to the battery which operates the spark plugs in the engine. The spark plug heats an electrical resistance wire which is wrapped around an asbestos wicking saturated with kerosene. The vapor from the kerosene in the wick is ignited immediately when the current is passed through the spark plug, thus providing for the instant starting of the car.

When the engine is effectively started this electrical heating element is discontinued, combustion in the mixing chamber continuing because of the air and finely divided kerosene passed in. By a system of choke plates similar in operation to the gauze of a miner's lamp the flame in the mixing chamber is prevented from extending beyond the carbureter into the engine. Only about 4 per cent of the vapor is consumed in the mixing chamber, it is claimed, due to a limited supply of oxygen and the speed with which the vapor passes through the carbureter, the rest passing the baffle plates in the form of a hot gas. The gasified oil is then mixed with air drawn through an auxiliary valve with a constant opening, and is then passed into the cylinders. Combustion is said to be clean with practically no carbon formation.

Breaking Up the Kerosene

The method of breaking up the kerosene is interesting. The kerosene passes through the ordinary type of float mechanism, flow being regulated by the suction of the cylinders at atmospheric pressure, and spreads out in a thin film between horizontal plates, around which air passes. These plates are pierced by numerous small holes, the upper plate having holes of a larger diameter than the lower one, which gives a pulverizing effect to the fuel. The inventor says:

"This method of carburetion secures complete gasification not only of the lighter distillates of petroleum but also of the heavy distillates, such as all grades of alcohol, kerosene and crude oil. The true gas I obtain from the heavier distillates is secured at atmospheric pressure and is a gas of a different character than is produced by any process with which I have heretofore been acquainted in that for a long period it will not condense at the ordinary atmospheric temperature.

"This gas when further mixed with air is highly explosive and leaves little or no carbon deposit in the cylinders. By use of the heating step in connection with the preliminary mixing it is not necessary to use the light distillates for starting the engine to raise the temperature of the working parts. Gasoline and other light distillates may be gasified without the use of the heating step."

U.S. Trucks in Mexico

A White truck train with the troops in Mexico, traveling in characteristic single file along a road paralleling the railroad

Above—Riker tank truck adopted by the War Department for carrying water and gasoline

Below—Mexican assisting U. S. officers who are stuck in a mudhole

By J. Edward Schipper

MEXICO is doing the automobile industry a good turn. Even the activities of the pernicious and elusive Villa have boomeranged to the benefit of a business which has seized some odd stepping stones in its upward climb. It remains for Mexico, however, to put the finishing touch by showing us very clearly what the limitations of our trucks are, and just what they can do with the odds all against them.

Every once in a while a story leaks through which shows that things are not as rosy for our motor transport on the Southern frontier as some of the more interested parties would like all hands to believe. Stories of broken wheels, broken springs, discarded engines and destroyed chassis are mingled as a piquant sauce with other stories of remarkable accomplishment, showing that smiles are being well mixed with tears along the Rio Grande.

The Governor Problem

To give an idea of the problems which confront those in charge of a truck company, nearly every one along the line is wishing for an invention which would govern a truck on a smooth road and take the governor off when it came to rough going through mud holes, etc. In the early days along the line, the main idea which possessed those in charge of the trucks was to conserve the vehicles as much as possible. Naturally some very strict regulations were made regarding governors and it meant a man's job if he were caught removing or tampering with the device.

Speeding on Good Roads

It is not difficult to picture the chagrin of a man who is stuck in a mud hole a great many miles from camp, unable to get through simply because he could not pull the pin out of his governor. They are being removed now, and the result is that human nature, or at least human nature as always shown by a driver, especially in khaki, is asserting itself along the better highways. The cars are being driven too rapidly in a great many instances.

How to employ momentum scientifically and with

Note the alkali dust thrown up by the wheels of the truck. This is a White truck train

Field generator and tractor with searchlight used by the U. S. Marine Corps

skill is the first lesson that is learned by all the rookie drivers. If a car stops in a difficult position, the difficulties are infinitely more than if the car kept going. The result of this is a great tendency for the driver to enter a bad stretch with a rush and dash, to carry the car through.

In some parts of the country where trucks have been used the stresses have been extraordinarily severe. This has been shown in frame distortion which has had its reflection throughout the entire car. Trucks which stand up on the roads in ordinary commercial practice, soon suffer from the extraordinary duties imposed in a country where the roads are roads in name only. The distortion of the frames has resulted in loose bodies and very often it occurs that the engines have become loose in the frame. Yet with all this difficulty and terrific stress, the trucks have done the work which they were sent down there to do. The point is that here is where each weak point is found out. It cannot be discovered, and the border work has become the greatest school of truck design that could ever be invented. What racing is to passenger car design, border work is to truck design.

There are a great many holes as well as a great many trucks, and the hole and truck combine to form a situation, at frequent intervals. It does not do a truck any good to race the engine up to a very high speed and then to let the clutch in suddenly, to get out of a mud hole. It is better to have a very low gear ratio to pull the truck out of the hole and this method is successfully employed on some of the later shipments of trucks. In other words, it is necessary to have high available torque at low speeds in order to overcome the road conditions.

Alkali Dust Causes Wear

If some device could be applied to the trucks for washing the air before it enters the engine it would be of advantage. As it is now, the alkali dust enters the cylinders and not only acts as an abrasive, but it seems to have an actual chemical action on the lubricating oil. Its action on the lubricant, whether chemical or mechanical, is certainly enough to cause rapid disintegration of the engine parts.

Springs naturally show the reflection of road conditions very quickly and there has been the normal amount of spring breakage, as would be expected. The cars that have been shipped down to the border have been in general equipped with the standard springs. As has been commonly observed in spring breakage, the fracture generally occurs on the rebound. It is quite possible that a large number of the spring breaks could be prevented by simply keeping a closer watch on the spring clips. These are bound to work loose and the spring is then deprived of a large part of its unit strength.

Racking Is Severe

It must be remembered that all the cars on the border, whether they are passenger cars or trucks, are submitted to a continual pounding and racking. Drivers say that the first few days in the seat of a car on the border is worse by far than learning to ride horseback. One reports that after riding several miles in an officer's touring car, he was unable to walk without stooping for 3 days. There have been many cases where a man sitting in the back of a touring car with the top up have been bounced so that their heads nearly went through the top material. It is necessary to hold fast to the top irons generally and a speed of more than 25 m.p.h. is rarely attained.

Every weak spot in a car is soon found out, and the manufacturers who have trucks on the border are making a mistake if some one from the engineering department is not watching developments.

Great Kerosene Activity in England

Government Reduction of Gasoline Supply Compels Development of Heavy Fuel Carbureters—One New Device Utilizes Jet of Exhaust Gas to Spray Fuel

By A. Ludlow Clayden

THE British government has recently introduced a system of supplying gasoline which has compelled every user to state the quantity he will require per month. When all the returns were in, the government issued tickets authorizing individuals to purchase a maximum quantity of gasoline (usually about 30 per cent of the amount applied for). These tickets remain in force for a period of 3 months entitling the purchaser to so much per month, *if he is able to buy it.* This means that every time a purchase of gasoline is made the quantity is to be checked off by the vendor and as soon as the recipient's card has been exhausted he can obtain no more until the end of the period.

A natural result has been the creation of tremendous interest in means for burning kerosene, the sale of which so far has been in no way restricted. To give an idea of the situation it may be mentioned that many owners of 30-hp. cars have been allowed 12 gal. or less of gasoline for the whole period of 3 months.

Gasoline in normal times has sold in England for approximately 30 cents a gallon and this price has not been high enough really to stimulate kerosene investigation. Now, however, that the alternative is kerosene or no motoring, the situation has been changed very greatly.

It is, of course, easy for users of automobiles in this country to be philosophic over the troubles of people on the other side of the Atlantic, but it seems probable that mankind in general will benefit very greatly from the restrictions imposed by the British government. The rising price of gasoline in America has stimulated investigation of the possibilities of kerosene but the encouragement now offered indirectly by the British government is a hundred times as strong.

Two Interesting Systems

The British automobile journals for the past few weeks have been filled with descriptions of kerosene carbureters and similar devices. It is noticeable that very many of these have originated in America and are already fairly well known on this side of the water. There have, however, recently been described by the *Commercial Motor* (London) two instruments which differ considerably from the majority of kerosene-burning carbureters. The first of these is the Halliday carbureter, which uses a water supply designed to moisten the air and to produce steam in the cylinders.

In describing the operation, the *Commercial Motor* says:

"Among the troubles encountered in burning kerosene in engines designed for gasoline are: excessive use of lubricating oil, owing in part to the higher temperature necessary when kerosene is being used; failure of lubricant because the kerosene has not been properly vaporized, or because it has again condensed in the cylinders and liquid kerosene has run down past the pistons into the crankcase, eventually thinning the lubricant to such an extent that it fails to act; excessive carbon deposit, and a tendency to knock on very little provocation.

"The outstanding feature of the Halliday carbureter, whereby it is claimed that these troubles are effectively eliminated, is the utilization of a jet of steam to accompany the ingoing charge of air and vaporized kerosene. It is very ingeniously designed, as a reference to the illustration will help to confirm. Briefly, the device consists of two float chambers, one containing gasoline, for starting purposes, and the other kerosene, both connected to the same jet, with a cock adapted to divert either fuel to the orifice as may be required. This jet is situated within a narrow venturi-shaped choke tube, of such a size that at slow speeds a fairly rich mixture is provided; at high speeds, the spring-controlled extra air valve dilutes the charge.

"So far as will be seen, the device differs but little from several other two-fuel fittings which we have hitherto described. The novelty consists of an additional jet to which water is supplied. This jet is situated in another choke tube controlled by a small throttle valve. The connections to the carbureter are so arranged that when gasoline is being used the small extra throttle valve is shut, but on the kerosene's being supplied, then this throttle valve is open, according to the strength of mixture required. From the water jet, an additional pipe runs to the main engine induction manifold, so that a percentage of moist air is carried into the cylinders with each charge. To this feature must be credited the efficiency of this carbureter. The effect of the inclusion of moist air in the charge is to cool it somewhat and thus allow a greater volumetric efficiency on the induction stroke. On explosion, the moisture in the air is converted into steam, the extra pressure thus obtained providing additional power, and cushioning the explosive effect.

"A new company has just been formed to proceed with the manufacture of this carbureter on a large scale. The name of the company is the Halliday Carburetter Co., Ltd., with temporary offices at Broad Sanctuary Chambers, Westminister, London, S. W."

Uses Exhaust for Spraying

The second instrument is called the Cairns Hevfuel Gasifier, which seems to operate on an entirely novel principle, the following being the *Commercial Motor's* description of the action:

"The Cairns Hevfuel Gasifier incorporates the feature, not hitherto described, of an exhaust gas injector, some of the spent gases being mixed with the fuel. On theoretical grounds one would be justified in casting doubts on the efficacy of such a proceeding. We have, however, already investigated privately the merits of one carbureter in which this is accomplished, and in the Cairns device, although exhaust gas is re-admitted, the quantity is very small.

"We have not been able to make a test of this carbureter, and can only repeat, therefore, the claims of the inventor as to its capabilities. He particularly emphasizes the fact that the heavy fuel is thoroughly vaporized and does not recondense; furthermore, that maximum heat and velocity with a minimum quantity of exhaust gas is utilized. Its fitment necessitates, as is now generally understood, the addi-

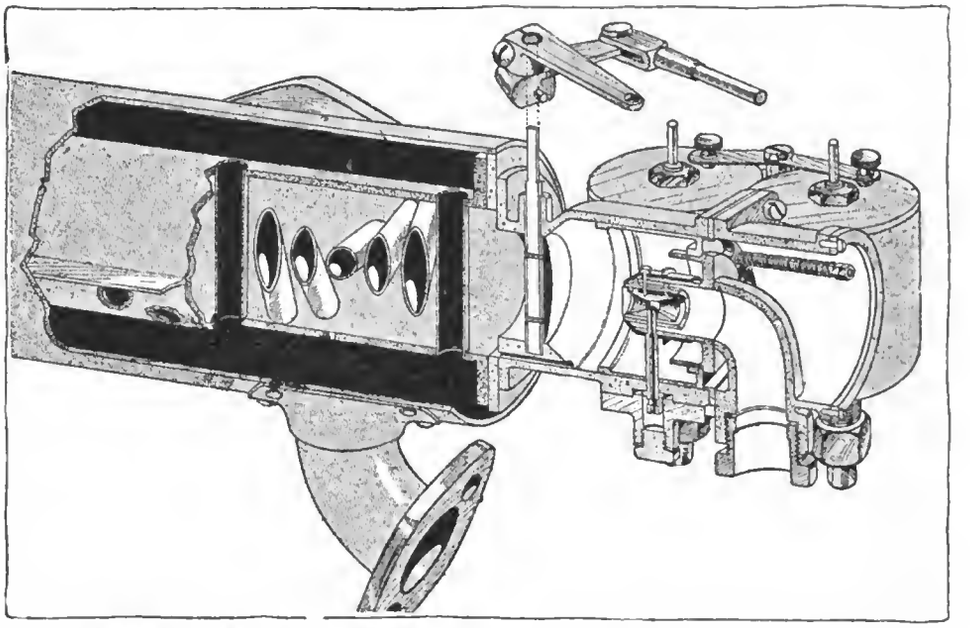
tion of a small supplementary tank for gasoline, utilizing the main reservoir for kerosene.

"The device consists of a kerosene float chamber and jet, a muff round the exhaust pipe, and centrally disposed inside this muff a tube inserted into the exhaust pipe, which serves to collect a small quantity of the spent gas, and directs it across the jet. Reference to our illustration will enable the reader to grasp the general arrangement of the fitting. It will be noted that it is entirely additional to, and separate from, the standard gasoline carbureter, interference with which is avoided, except that the connection from the kerosene carbureter is made to the main air inlet of the gasoline carbureter.

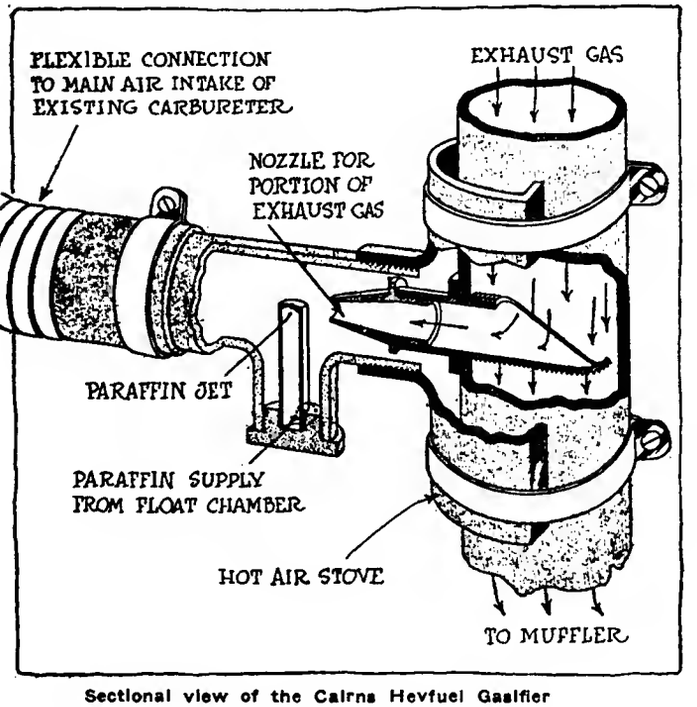
"In action the device provides that the blast of hot gas at high velocity is driven across the top of the fuel jet, atomizing and vaporizing the kerosene. A small amount of air for preliminary dilution purposes is drawn in by the injector action of the nozzle, not sufficient, however, to give a combustible mixture, but providing a gas rich in fuel. This rich mixture is taken through a flexible pipe, which is covered with non-conducting material, to the main air inlet of the gasoline carbureter, where provision is made for further dilution by means of an extra air control. The ordinary gasoline carbureter throttle-valve is utilized to regulate the supply of gas to the engine. It is claimed that the user can change over to heavy fuel after a minute's running of the engine on gasoline. We understand that the inventor, Thomas Walker Cairns, of 2 North Road, Birkenhead, England, will consider an arrangement to manufacture commercially in quantities."

This seems to be a particularly interesting device but it is not obvious what will be the effect of speed or load upon the operation. In a kerosene vaporizer more heat in proportion to the amount of kerosene used is required when running at low throttle than when running at full power. There seems, however, no reason why the Cairns carbureter should not be so designed that it will conform very closely to the ideal conditions. The principle appears to be an advance upon those of several other inventors who have actually ignited and burned a small portion of the kerosene, using the heat so evolved to vaporize the remaining portion.

With nearly all kerosene carbureters it is necessary to start the engine on kerosene and change over the heavier fuel when the engine is running. This necessitates carrying two fuels and it is therefore somewhat of a nuisance.



Halliday carbureter and vaporizer in detail. This device has a water supply as well as one for kerosene. The two bowls are for kerosene and gasoline



Sectional view of the Cairns Hevfuel Gasifier

Starting on Kerosene

The two British papers, the *Light Car* and *The Autocar*, have recently been discussing methods for starting up on kerosene direct, and one ingenious idea suggested is to warm up the intake manifold, or the vaporizer, by heat obtained from two or three small gas jets which can be coupled up to the ordinary household supply before starting out in the morning. Once the vaporizer and intake manifold are warmed the car can run all day on kerosene without trouble, provided the engine is not allowed to stop altogether for more than a few minutes at a time.

Another suggestion is to place a small boiler on the fire, taking the steam created into the radiator by means of a flexible pipe. This steam bubbling through the water will soon bring it to near the boiling point and this, it is stated, is hot enough to allow a start to be made on kerosene. The writer has found in warm weather that it is often quite possible to start on kerosene by first injecting a very small quantity of ether into the intake manifold or cylinders.

Having regard to the electrical equipment of most modern automobiles it appears that far the best way to get a start on kerosene would be to spray the fuel onto a coil which could easily be raised to a red heat by the battery current. A throttle placed in the exhaust pipe could be almost closed to make the manifold heat up quickly, so as to allow the current to be switched off swiftly.

Those vitally interested in the kerosene carbureter problem should pay close attention to British contemporary literature during the next 6 months, for undoubtedly it will contain practically everything that is known regarding the application of moderately heavy oil to automobile usage.

Heat Deteriorates Cast Iron

Cylinders and Piston Heads in Large Oil Engines Slowly Oxidized by Temperature of Explosion —Nature of Grain of Iron Affects the Action

THE issue of *Engineering* (England) for Aug. 4 contains an interesting article by J. E. Hurst entitled, "The Growth of Internal Combustion Engine Cylinders," dealing with the phenomenon of "growth" in the cylinders of large oil engines, particularly Diesel engines. The author first mentions cases where gray iron structures have failed when subjected to frequent and violent changes of temperature, such as the appearance of cracks in cast iron fittings of superheated steam mains. In the original investigation of the problem the conclusion reached was that the hot gases of a furnace can penetrate the iron by way of the graphite plates which are a constituent of cast iron. Long action results in the oxidation of the graphite contained and also, to some extent, of the iron itself.

Regarding the effects observed in the cylinders of internal combustion engines, the author says:

"Experience with internal-combustion engine liners shows a phenomenon which would appear to be very much allied to this 'growth.' When a new liner is put to work it is invariably necessary to make some slight adjustment to the piston. Apart from such considerations as slight inaccuracies in machining, etc., this adjustment is often necessary owing to the slight changes in volume of the cast iron of which the liner and piston are constituted. This is further borne out by the fact that looking back over a series of examples the character of the iron would seem to influence the extent of adjustment to be made. If the iron should be in any degree open grained, or rather contain more large graphite plates, the degree of adjustment necessary is greater than in the opposite case. In so far as can be judged by observation over a long period, the grain size, and more particularly the size of the graphite, is the controlling factor. The difficulty of obtaining any definite information as to the cause of this phenomenon will no doubt be obvious. The miscroscope gives little information.

Expansion in Grains

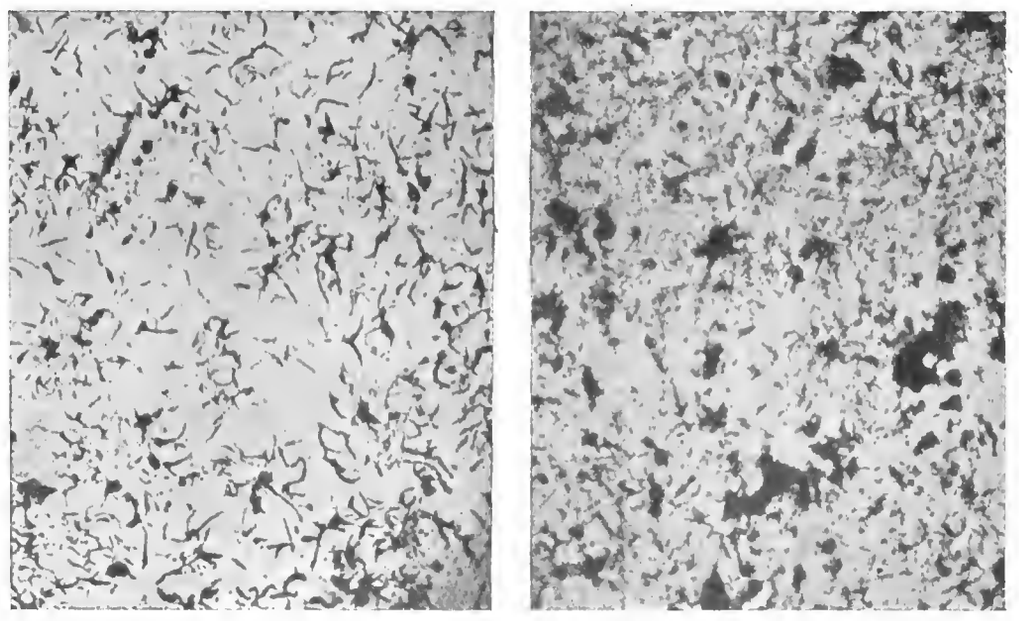
However, in the author's opinion this change in volume would seem to be due to an expansion among the grains composing the liner and piston surfaces, brought about by the rapid succession of changes of pressure within the cylinder. This results in the entrance of gases and lubricant into the interstices of the grains by way of the graphite plates, an action which is no doubt facilitated by heat; hence the slight changes of volume.

"Experience with micro-sections from such surfaces frequently shows the presence of lubricant, which is ofttimes troublesome during the preparation of such specimens, even after the specimens have to all intents and purposes been thoroughly cleaned.

"Undoubtedly this phenomenon results in a falling off of the mechanical strength figure; but it is considered that the change in volume is confined to a comparatively thin layer of the surface only, and it is obvious that the extent will be controlled largely by the grain size and the internal pressure.

"*A loosening of the surface grains is an invariable consequence of this change in volume, a factor which is of great importance in determining the wear of liners and pistons.*

"In the internal-combustion engine, and more particularly in engines of the Diesel type, the piston head is heated to an excessive temperature, quite distinctly red. This heating is local and extends over an area in the center of the piston head, on which the flame produced by the combustion of the charge impinges. The effect of this heat on the material composing the piston is to eat away a layer of the metal, and if the material be certain kinds of cast iron radiating cracks are produced extending from the center of the heated area across the piston head. Such cracks are commonly put down to the growth of the metal under the influence of the alternate heating and cooling. However, an examination of specimens of this type of occurrence would lead one to the conclusion that this is not growth in the strict sense of the term. The chemical analysis of such specimens does not undergo any appreciable change in total composition, nor is there any trace of oxidation in the actual metal; and further, in direct opposition to Carpenter and Rugan's conclusions respecting growth, a reduction of the phosphorus content of



Left—Fig. 1—Normal iron, showing graphite plates. Unetched. Right—Fig. 2—Heat-treated iron, showing swelled graphite. Unetched. Both are magnified seventy-eight diameters

the iron entirely eliminates all these troublesome cracks.

"Undoubtedly these cracks are the product of a series of events occurring internally in the cast iron under the special circumstances. On heating common foundry iron up to a temperature of from 750 to 900 deg. C., a range of temperatures which includes that of the Diesel engine piston top, it is observed that some of the graphite is absorbed, forming the austenite (hardenite) solid solution. The extent of the graphite absorption at any particular temperature depends largely upon the time of heating and the volume of the material. This absorption is accompanied by a formation of numerous cavities larger in cross-sectional area than the original graphite plates, Figs. 1 and 2. On cooling down slowly the free carbon is redeposited, but this time it is not necessarily in the graphitic form, but in a condition more of the nature of temper carbon. The phosphorus assists this absorption of carbon considerably, though exactly the manner in which it does so is as yet somewhat obscure. It is observed that the absorption of carbon takes place with increased rapidity in the high phosphorus irons, while in low phosphorus irons the action is brought about with some difficulty. It is further noted that at the higher temperature, 900 deg. C., the phosphorus tends to liquate and aggregate into larger rounded areas. In the red-hot piston top of the Diesel engine some of the free carbon is absorbed in a like manner as above described. The extent of carbon absorbed, limited, of course by the saturation point at the particular temperature, depends largely on the length of time and the bulk of the metal heated, and in addition on influence of the phosphorus content. On cooling down this absorbed carbon is deposited in the temper carbon form, a fact which will account for the distinctive grayness of these overheated pistons when fractured. This absorption and re-precipitation of the carbon alone, apart from the expansion of the graphite plates shown in Fig. 2, the reason for which is not quite clear, will set up a series of repeated expansions and contractions, the effect of which will be obvious. In addition, it will be appreciated that at the temperature of this particular portion of the piston the phosphide eutectic is perilously near to its melting point, and it is in all probability a fact that liquation does occur, a phenomenon which will further assist in the production of cracks.

"The high and constantly changing gas pressure in Diesel engine cylinders will also largely assist in the production of cracks by the gas forcing its way into the cavities and cracks produced by the absorption of the graphite, and the liquation of the phosphide eutectic, and there assisting in the rending apart of the component grains. This action is not confined to a thin layer of the exterior surface only, but extends right into the interior of the metal. In this respect it is unlike the former case mentioned.

"In the case of low phosphorus irons, in which the chances of liquation of phosphide eutectic are reduced to a minimum, all trouble from cracked piston heads is practically absent."

Naturally automobile engines are not subject to quite the same severe conditions as the bigger engines of Diesel type, but the phenomenon of cast iron deterioration in exhaust pipes and muffler parts is well known. Also, it seems possible that cylinder wear might be reduced by choosing the cast iron best suited to the high temperature conditions; that is, the low phosphorus iron. In the large cylinders or tractor engines the nature of the iron might reasonably be expected to have an effect upon the wear.

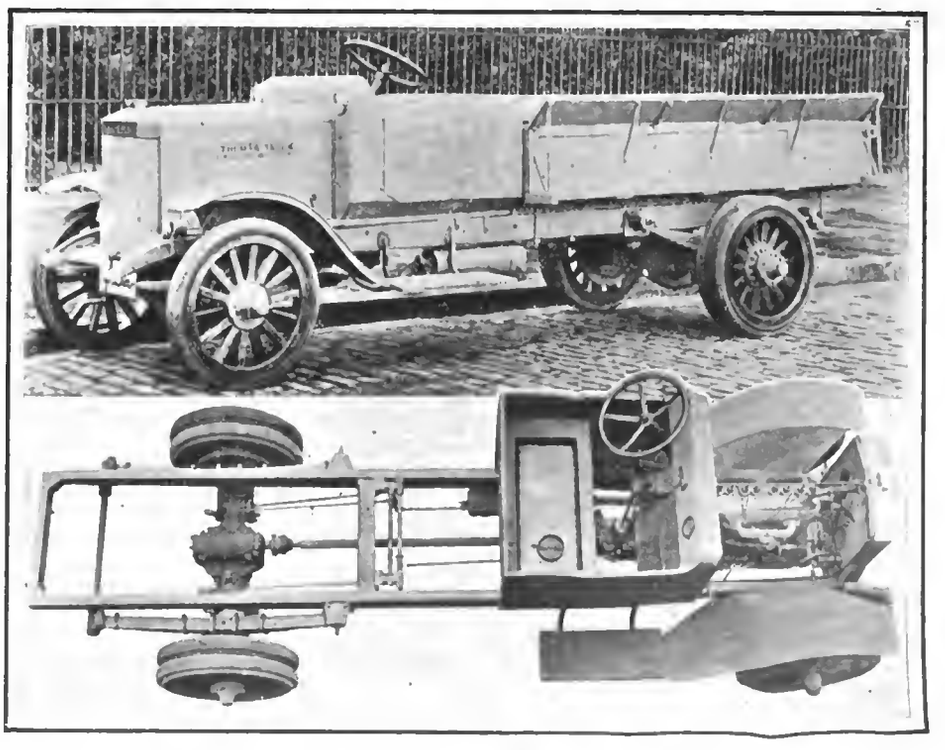
Harder Iron Shows Less Friction

Mr. Hurst's article recalls to the present writer a puzzling case where two different sorts of iron were used for two cylinder blocks otherwise precisely similar, and a horsepower test with all other parts of the engine unchanged, showed the harder iron to have less friction. Speaking from memory, the soft iron cylinders gave a maximum b.h.p. of 42 and the hard iron 45 at the same crankshaft speed. The sizes of the combustion spaces and the accuracy of the bores was checked carefully and there was no difference, so that the only explanation possible was that the hard iron was the better to lubricate. Both cylinders were ground on a Heald grinder.

There is more to be known about cylinder irons, and the subject is one that has been very much neglected.

Thomas Cab Protects Driver

THE Thomas Auto Truck Co., 639 West 51st Street, New York City, was organized early this year to make a ¾-ton, a 1-ton, a 1½-ton and a 2-ton truck. The 2-ton is shown in the accompanying illustrations. The engine is a Buda, 4⅛ by 5½ in. with Bosch fixed spark magneto. There is a dry disk clutch and a unit gearbox with three speeds, the rear axle being a Timken worm drive design. The wheelbase is variable to order, the standard length being 150 in. and the alternative 166 in. Special attention is drawn to the protection afforded to the driver by the high side doors to the cab and the passenger car type of cowl. Bosch lighting and generator and battery is provided and the equipment includes a windshield and a bumper in addition to all the usual accessories. Tires are 34 by 4 in., dual on the rear.



The Rostrum

Six-Cylinder Firing Order

EDITOR THE AUTOMOBILE:—I notice in the Rostrum of THE AUTOMOBILE for Aug. 10 that B. Bros. ask: "Will a six-cylinder motor firing 1, 2, 3, 6, 5, 4 develop as much power at 1500 r.p.m. as one firing in the conventional order?" If a plain crankshaft is used I agree with your answer, but please express your opinion when a seven-bearing crankshaft is used, having twelve balance weights of proper size and shape fixed to it.

2—Is it not easier on crankshaft and bearings to balance each individual cylinder with two balance weights, one on each side, so that each cylinder will have its own balance more nearly in its own plane?

3—I do not see why this construction firing 1, 2, 3, 6, 5, 4 should not be freer from vibration on account of less tendency to rock the ends of the engine.

Tampa, Fla. L. C. H.

—With the firing you suggest the bearings would be stressed to a considerably more severe degree than with the conventional firing, since all the stresses would be at one end of the shaft. It must be remembered that in a six-cylinder engine the explosions are 120 deg. apart and with the firing you mention the shaft would be first stressed on one end and then on the other so that the explosion strokes would not tend to offset one another as they do with conventional firing, but would merely multiply the intensity through overlapping.

2—In balancing a six-cylinder crankshaft it is necessary to take into consideration the longitudinal rocking action as well as the horizontal components of each individual cylinder, therefore, even though each cylinder is balanced independently in certain respects the other cylinders must be considered.

3—With the firing you mention the tendency to rock the ends of the motor would be greater than with the conventional firing, that is, the vertical moment of the shaft about its center would be greater.

Chevrolet 490 Now Being Made

Editor THE AUTOMOBILE:—Are the manufacturers of the Chevrolet automobile building or putting on the market for 1917, the car which has been called the 490 Chevrolet, or has this model been discontinued?

Eden Center, N. Y. G. H. B.

—The 490 Chevrolet is being actively manufactured, the 1917 models being equipped with electric starting and lighting, which equipment was not standard on previous models.

Broke Two Crankshafts in Few Months

Editor THE AUTOMOBILE:—I have a 1914 model Ford in which I have broken two crankshafts in the past few months —in both instances was driving the car on smooth road at about 20 m.p.h. Both shafts broke in the same place, just forward of the rear main bearing, and after taking the motor down I failed to find anything out of true either time. The bearings were fairly tight and no lost motion to amount to anything anywhere. I drive with the spark advanced all it will bear without causing the engine to knock. I was wondering if it could be possible that by giving the motor the gas too suddenly with the spark advanced all the way down while driving at a speed of 20 m.p.h. would have anything to do with the crankshafts breaking.

I have been serving as automobile mechanic for the past 4 years, but I admit that I am at a loss to understand the cause of this trouble.

Carbon Hill, Ala. L. S.

—Without seeing the crankshaft it is quite difficult to pass upon the causes of trouble. It is hardly possible that the trouble results from defective material, as it is unlikely that you would receive two shafts which are not up to standard in so short a period. Neither does it seem possible that the trouble could result from manipulation of the spark and throttle in the way you suggest.

Investigation will probably show that the trouble results from crystallization following operation in a motor in which insufficient oil has been used at some time. It may also be due to loose or improperly adjusted bearings or to some part of the motor being out of line. This condition could come from a continuous misfiring of the engine.

Howling in Axle of 1916 Car

Editor THE AUTOMOBILE:—Can you advise me of any remedy for a howling in the rear axle of a new 1916 model? I understand there is some means of tapping the torsion tube which will stop this howling.

Madison, Wis. R. W. D.

—It is not advisable to tap the torsion tube, although this would cut down the resonance. In all probability as soon as the gears have worn in a while this howling will stop.

Connecting-Rod Bearings Not Right

Editor THE AUTOMOBILE:—I am having trouble with a 1912 Ford. I overhauled it last spring and took up the main bearings. The owner took it out and the second time he drove it he ran out of oil and burnt the bearings. We were able to scrape the burned part out, but now the engine runs very hot so that the exhaust pipe is red all the time and the water boils after a short run and the bearings keep loosening up. Before the car runs 100 miles a knock commences and grows worse gradually until we take up the bearings again.

2—We have moved the timing gears one cog both ways from the marking but it makes no difference with the heating. Can you tell me what makes it run so hot and why the bearings do not stay after being taken up?

3—What kind of babbitt is used in a Ford?

4—What is the exact valve timing of a Ford?

Bloomingdale, N. Y. R. C. A.

—It is very probable that the trouble in this case results from the fact that proper repairs were not made after the engine was operated without oil. Apparently all that was done was to scrape out the bearings and draw the caps up tighter. If the parts were burnt the connecting-rod bearings should have been replaced and the motor block rebabbitted and new crankshaft bearing caps fitted. Probably it would be better where the damage is as extensive as this to have the car brought to a large service station where the equipment will be found to carry out the work.

2—The model T timing gears are properly set when the motor leaves the factory and the adjustments should not be changed, that is, the engagement of the gears should not be altered, as it is likely to cause trouble.

3—A nickel babbitt is used in Ford cars. It must be remembered that the rebabbitting of a cylinder block is a difficult operation. It requires more than a skilled mechanic as special equipment is necessary.

4—In timing the valves the teeth of the crankshaft and timing gears should be brought together so that the tooth on the small gear which carries the zero mark will mesh between the two teeth of the large timing gear at the zero mark on the large gear.

Why Tires Are Marked on Outside

Editor THE AUTOMOBILE:—Kindly advise me whether or not it is for the purpose of advertising or otherwise that tire companies mark their tires "Apply this side first."

Rainbow Lake, N. Y. J. H. W.

—Tires that are marked on the outside only carry this sign on the inside. Most of the manufacturers do not mark their tires in this way. It may be that some of the tire manufacturers mark their cars in this way on account of the flaps which are, in many cases, cemented in. Other manufacturers do not cement their flaps and hence would not need this marking. In all probability, however, where the lettering you state is used it is merely to bring the other markings outside.

Scripps-Booth 1917 Cars Now Out

Editor THE AUTOMOBILE:—Are the Scripps-Booth cars which are at present coming through production the 1917 models, especially the four-cylinder roadster?

2—Is it the policy of the Scripps-Booth company to announce yearly models?

3—What improvement will the 1917 model roadsters have over the same models this year?

Auburn, N. Y. B. H. F.

—The Scripps-Booth cars which are now coming through production are the 1917 models.

2—It is not the policy of the Scripps-Booth company to announce yearly models.

3—The 1917 model now on sale is fitted with the inclosed valve mechanism and a two-unit starting and lighting system instead of a one-unit system used in last year's model. It is also equipped with a bevel gear rear axle.

Miller Car Not Built at Present

Editor THE AUTOMOBILE:—I note in THE AUTOMOBILE for Aug. 10, on page 242, an inquiry in reference to the builder of a Miller car. You will find a reference to this car in *Motor World* for Feb. 29, 1912.

Glenbrook, Conn. C. L. C.

—The Miller car is no longer built. It was manufactured by the Miller Car Co., of Detroit, Mich., had a 30-hp. L-head motor with a bore and stroke of 3¼ by 5 in. Leather-faced clutch, three-speed gearbox and 34 by 3½ front with 34 by 4 rear tires were among the specifications.

Wants Stationary Power Plant Engine

Editor THE AUTOMOBILE:—Will you kindly give your views on the following questions:

1—Are the present-day kerosene and crude oil engines giving satisfactory service? That is, do they require an expert to attend them? We are intending to install a small power plant in the Isle of Pines, Cuba, and on account of the price of fuel are naturally anxious to cut expenses of same to the minimum figure.

2—Are the Diesel types of engine satisfactory?

3—Please give names of leading manufacturers of heavy fuel engines. Also the engine that is considered the leader, if possible.

Manchester, Vt. R. P. M. Co.

—At the present day developments in large unit or stationary heavy fuel engines are such that they are reliable and do not require anyone but a fair mechanic to attend them.

2—Diesel engines are very satisfactory.

3—If you will write THE AUTOMOBILE, mentioning the size of engine you require and what its purpose will be, the desired information will be supplied.

Wiring Diagram of Entz-Chalmers

Editor THE AUTOMOBILE:—Kindly publish a wiring diagram of the Dyneto-Entz motor generator as used on Chalmers cars.

New Brunswick, N. J. A. K. F.

—The motor generator as used on Chalmers cars was manufactured by the Chalmers company under the Entz patent. The wiring diagram of the Entz-Chalmers is shown in Fig. 1.

Use Dull Paint Under Varnish

Editor THE AUTOMOBILE:—I have a Ford roadster and want to repaint it. I want the running gear a bright red, the fenders black and the body blue. In painting it would it be advisable to use a paint with a glossy finish over old paint or to use a dull finish paint and varnish it afterward?

Bellerose, N. Y. D. M. L.

—It would be better to use a dull-colored paint rubbed down and finished with varnish. You can obtain the materials required at any paint store.

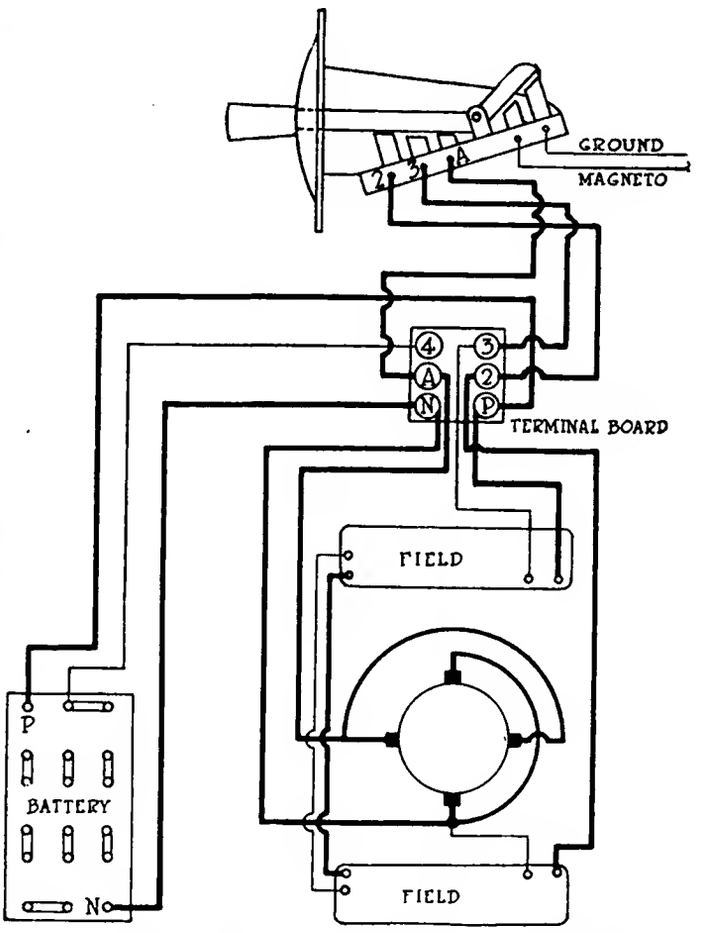


Fig. 1—Wiring diagram of Chalmers-Entz motor-generator

Doble Steam Car Is Up-to-Date

Limited Number of High-Class Chassis To Be Built and Fitted with Custom Bodies — Power Plant Embodies Refinements—Starting Is Instantaneous

ABNER DOBLE, who for a number of years has been experimenting with steam automobiles, has appeared in Detroit with a newer design of vehicle that adheres to the same general principles as the first steam car he brought out about 2 years ago, but embodies a number of later ideas that bring it strictly up to date.

A company has been organized here to be known as the General Engineering Co., with Doble as one of the officers, and this organization is to build a limited number of the steam vehicles, with bodies designed by Holbrook. These cars will be in the high-priced class and excellently appointed and constructed in every particular, it is stated. In addition, the concern plans to license manufacturers to use the Doble system of steam propulsion, which, by the way, can be constructed of a size to meet the requirements of any chassis.

Briefly, the Doble steam car employs a vertical-tube steam generator placed under the hood, where the engine would be in a gasoline car, and under this is placed a combustion chamber lined with a refractory material. Kerosene is introduced here, and ignited by a point, electrically heated to sufficient temperature to ignite the kerosene. The steam is then passed back to a two-cylinder engine mounted in unit with the rear axle. A condenser is utilized, so that the steam is re-converted into water and used over again. The kerosene tank is mounted at the rear of the chassis, just as a gasoline reservoir would be carried.

Aside from the advantage of not requiring a new supply of water at frequent intervals, the Doble car starts practically instantaneously, although steam is not already up. All that is necessary to start and run the car is to turn the switch to the running position. This heats the igniter point and ignites the fuel. Then the throttle is opened and the machine starts immediately. In case the car has been inactive for several days, so that everything is cold, it takes about 1½ min. to start, but after a wait of a few hours, such as over night, the machine can be started at once. In case the electric switch is left in the running position, the steam pressure remains at the normal point continuously.

No clutch nor gearset is used. Power is transmitted to the rear axle by spur gears, a forty-seven-toothed gear on the engine crankshaft and a forty-nine-toothed gear on the differential. That reduction gears are not required was demonstrated by the fact that the engine had more power than was needed to spin the wheels from rest on a dry pavement.

Water Tube Generator

The water tube generator consists primarily of a number of identical sections placed in an insulated casing. These sections consist of two horizontal headers connected by sixteen vertical tubes. The headers and tubes are made from cold drawn seamless steel tubing, and the tubes are welded to the headers by the autogenous acetylene process, making the section of one piece of steel. The tube is swaged down to about ⅝ in. at the weld, thus reducing the amount of welding required and also making the weld stronger than if it were the full diameter of the tube.

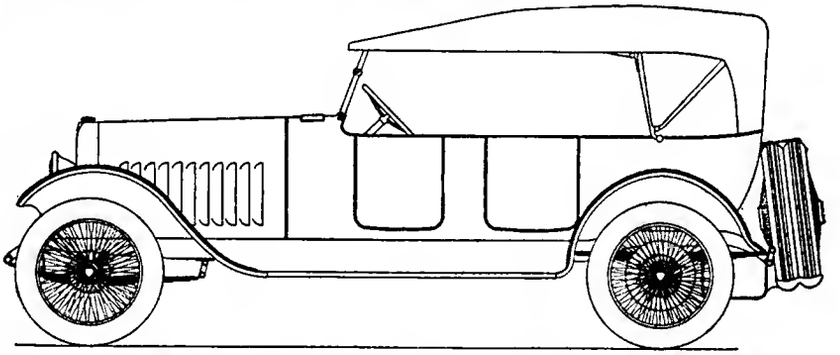
About one-third of the sections are used as the economizer, and the remaining sections form the evaporating part of the generator. The water enters the generator through the lower headers of the economizer and rises through the tubes to the top headers, becoming heated on its way by the gases that have passed through the evaporator portion of the generator. From the top headers of the economizer the water is fed through a pipe to the bottom headers of the evaporator sections. The water level is maintained automatically about half way up the generator. The steam rises through the upper part of the tubes, becoming superheated on the way, and goes out through the upper headers into the steam pipe, where it is led to the engine. The amount of steam passing is regulated by a throttle valve.

The combustion takes place in a combustion chamber of efficient design, made of a special refractory material, which attains a very high temperature, and insures efficient combustion, by heating the gases before they burn, and by catalytic action. The gases rise past the tubes of the evaporator portion, and are then passed over a bridge wall and down past the tubes of the economizer portion, where the remaining heat units are abstracted by the relatively cool water entering the generator by way of the economizer.

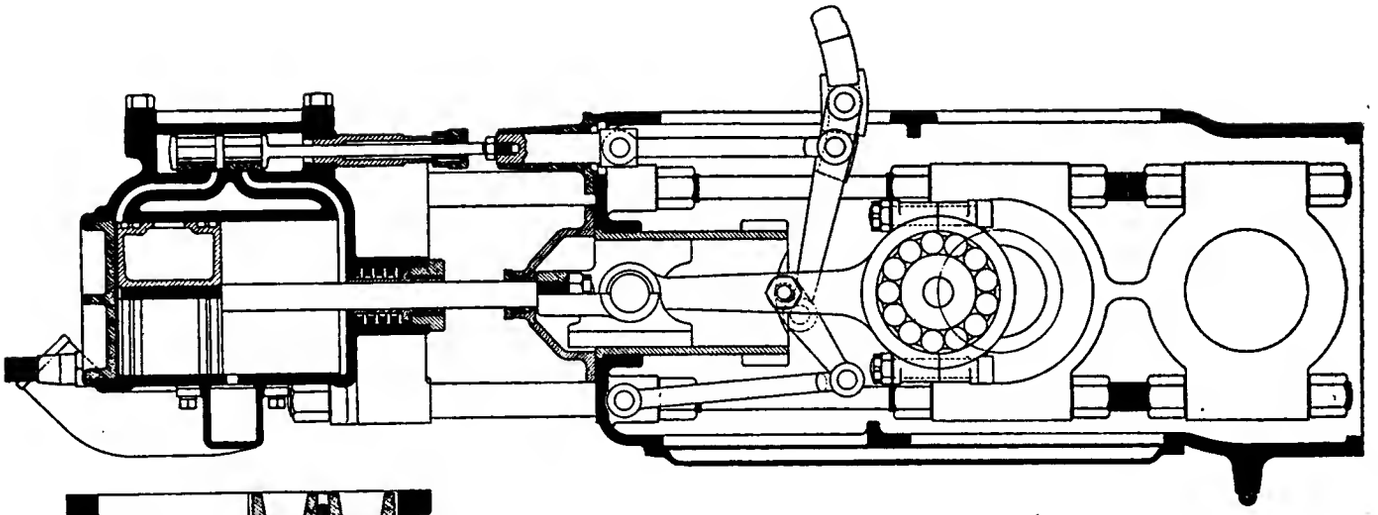
Two-Cylinder, Double-Acting Engine

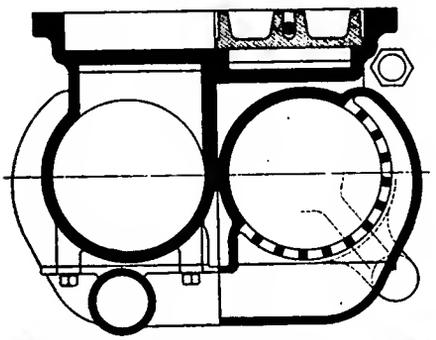
Thus, the fuel is burned by means of a system that eliminates any attention or labor on the part of the driver, and reduces the time necessary to start the car from cold by the amount formerly necessary to properly pre-heat the vaporizer. This has been accomplished by taking a few pointers from internal combustion motor design, broadly following the same idea whereby air is made to pass through a device which mixes into it a correct amount of fuel, then this mixture is led into the combustion chamber described above in connection with the generator, where it is ignited by means of electricity. In order to cause the air to flow, a small blower is used, and is driven by an electric motor, such as is used in vacuum cleaners. This blower forces air through the carbureter into the combustion chamber.

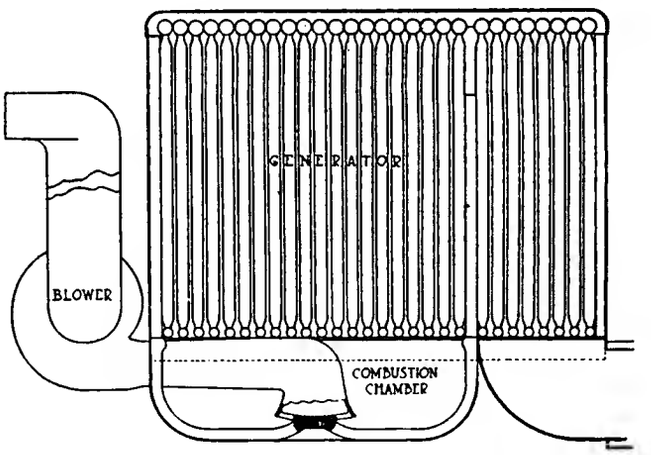
The steam is used in a simple, uni-flow, double-acting, two cylinder, locomotive type, steam engine, with a bore of 5 in.



Illustrating the lines of the Doble steam car to be manufactured in Detroit. Note the similarity to a gasoline car of the modern streamline type







Above—Plan section of the two-cylinder, double-acting locomotive type steam engine to be used in the Doble steam car. It has a bore of 5 in. and a stroke of 4 in. The steam travels through it in only one direction
Right—Water tube type steam generator consisting of two vertical headers connected by sixteen vertical tubes. One-third of the sections are used as the economizer and the rest form the evaporating part of the generator

and a stroke of 4 in. This type of steam engine is one in which the steam travels through it in one direction only; that is, it goes from the cylinder head to the center exhaust port. The slide valves are on top of the cylinders, and are actuated by a Joy valve-gear. This gear dispenses with the need for eccentrics, thus making a one-piece crankshaft possible, and gives a superior steam distribution. The gear also reverses the engine without the need of extra devices. The cut-off can be set at any desired point, three being the usual number of cut-offs provided. In operation three-quarters cut-off is used for starting or heavy going, three-eighths for ordinary running and accelerating and one-eighth for high speed and high economy work.

After the steam has done its work in the engine, it is led to the top of the radiator, and in passing down through the tubes, gives its heat up to the air passing through the radiator and condenses into water. The water of condensation returns to the water-tank, where it enters near the bottom, so that at nearly all times the opening is below the surface of the water.

Piston-rods pass through special solid cast-iron glands, which are made such good fit on the piston-rod that no steam can blow by. Due to the long bearing surface there is practically no wear, and never any need for repacking, it is said.

The crankcase is a well-proportioned aluminum casting, and contains the entire moving parts of the engine except the pistons and valves. The differential is also contained in the crankcase, and the taper-tubes of the axle bolt directly to it. Thus the engine and rear axle are one unit.

The main bearings, and the big end connecting-rod bearings are annular roller, and are of such proportions that no wear should occur during the natural life of the car. All of the other bearings such as the wristpins and valve gear bearings are hardened steel, running in hardened steel bushings.

The power is transmitted to the rear axle by means of two perfectly cut spur gears, a forty-seven tooth gear on the engine crankshaft and a forty-nine tooth gear on the differential. There are no change-speed gears and no clutch, and the engine has more power than is needed to spin the wheels from rest on a dry pavement, as was demonstrated.

The electric system, to take care of the lights, horn and combustion system, comprises a dynamo and a storage battery. The dynamo is driven from the main axle drive gear.

Truck and Tractor Engines—Part I

(*Continued from page* 390)

Curve *T.R.*, Fig. 3, represents the tractive resistance at various truck speeds and illustrates the surplus in power required in common practice for running on level roads with low tractive resistance.

Running under the conditions as indicated above, the load on the motor would be about 33 per cent. The best economy that would be expected would be from 0.9 to 1.0 per hp.-hr. and this would be seldom attained in service. By using a four-speed transmission the horsepower required to pull the load would remain the same, while the speed of the engine would drop; therefore, the speed at which the engine would have to operate without changing gears should be established by speed of maximum torque. The steps in transmissions are governed by this range of speed. Referring to diagram Fig. 3 it is easily seen that the engine would be between the one-half and three-quarter full torque, resulting in economy of 0.8 lb. per hp.-hr.

(*To be Continued*)

A-B-C starting and lighting system mounted on Ford engine

Accessibility Features A-B-C System

6-Volt Electric System for Fords Has Low Initial Draw on Battery

SEVERAL marked advantages are claimed for the two-unit, 6-volt starting and lighting system for Fords made by the A-B-C Starter Co., Detroit, Mich., and selling for $85 installed. It is the design of Alexander Churchward, well-known starting and lighting expert, who is vice-president and engineer. Special importance is attached to the fact that the system does not interfere with the accessibility of the engine and is itself accessible. It takes only a small amount of the engine power as the generator is only ⅛ hp. The supporting brackets are so designed that they do not put an undue strain on any of the engine parts. Another important feature is that no changes in the Ford construction are made.

The generator is mounted at the left front of the motor on a bracket which is supported from the crankcase, longer crankcase bolts being used. It is driven by a broad, flat belt from the regular crankshaft fan driving pulley. The fan pulley itself acts as an idler and the spring keeps the belt taut. A Ward Leonard current regulator is mounted on the top of the machine.

Starting motor is placed on the right, forward of the carbureter and is carried on a cradle bolted to the crankcase flange on one side and supported on the other side by a lip around the edge of the frame.

A double reduction is used, the first being through spur gears and thence through a roller chain which drives through a shaft connecting with the front of the crankshaft. This mechanism is carried in a rigid casting anchored to the front spring clips.

There are two innovations in the design of the starting apparatus: One is the use of a cushioning spring interposed between the ends of the armature shaft and the starter reducing gear, so that the actual inertia of the armature may be used to give the high initial pull required to overcoming the high starting friction. The result is that the initial draw on the battery is much less than if the armature were solidly connected; thus a 60-amp. hr. battery suffices. The second point of interest is the method of engaging and disengaging the starter clutch. The principle is somewhat similar to the Bendix drive. When the starter begins to rotate the driving member of this clutch slides forward and engages the crankshaft. This sliding motion is obtained by cutting a spiral thread on the outside of the sleeve and having meshed with it another sleeve or nut which is held from sliding by a loose-fitting collar. This sleeve is free to rotate, yet the collar produces sufficient friction so that when the starter begins to operate the inner sleeve is held back so that the outer one may be screwed forward into engagement.

The device is disengaged automatically, the motor running away from the starter and thus drawing it out of engagement.

The lighting switch is placed on a panel at the left on the dash and the starting motor is operated through a small pedal in the floorboard.

Equipment includes ammeter, starting switch, lighting switch with dimmer attachment, etc.

Bits of Ball-Bearing Experience

Prominent Engineers Contribute Information Regarding Care and Installation of Annular Bearings—Chemically Neutral Lubricant Must Be Used

In carrying out some research work on ball bearings, the S. K. F. Ball Bearing Co. has obtained the opinions of a numher of automobile engineers on points pertinent to annular installations and their care. Taking as a basis the statistics compiled for the annual show numher of THE AUTOMOBILE, it has been found that the manufacturers of 1916 passenger cars use ball bearings to the extent of 67.2 per cent in the gearhox, 56 per cent in the front wheels, and with varying percentages in other parts of the chassis. This is hased on the number of models and not on car production.

A symposium was conducted among the engineers of the country using ball hearing installations to secure from them what thoughts came up in their mind in connection with this type of bearing installation, and as a result a number of interesting though unclassified facts were gathered in. Probahly of most interest to the consumer were the points mentioned on lubrication. In commenting on this phase of hall bearing practice, the engineers who responded were almost unanimous in stating that the luhricant used must be chemically neutral, that is, neither acid nor alkaline.

Both Grease and Oil

The actual lubricant used varied according to the general opinions with the duty which the bearing performs. There is a slight difference of opinion, however, regarding the weight of the grease or oil to be used in different places. F. A. Whitten, of the General Motors Truck Co., states that a very light neutral grease or non-fluid oil should be used in almost all of the hall bearings, although in a few places a heavy oil can he advantageously employed. A. L. Riker, of the Locomobile company, finds that ball hearings ·hould be luhricated with a grease containing no acid. For detailed usage W. P. Chrystler, of the Buick company, recommends steam cylinder oil for the gearset and rear axle and also steering gear and a soft cup grease for the front and rear wheels and the clutch.

W. G. Wall, of the National company, mentions a fact which should be given heed, and that is that there should he a considerahle source of lubricant for ball bearings in places exposed to heat, as around the engine. Regarding the clutch C. Biedermann, of the O. Armleder company, says that manufacturers of drive plate clutches cannot afford to ignore the lubrication of the clutch. If the clutch runs without oil then the system of hearing luhrication must he complete in every detail. The clutch pilot bearing will not run without oil and the clutch throwout bearing cannot endure more than a few days without oil. Transmission oil must be guaranteed to be free from acids, alkalis, water or any gumming mixtures used to ohtain quiet gears.

In regard to the mounting of hall bearings and the selection of the bearing size, several interesting comments were made. C. W. McKinley, of the Willys-Overland company, in mentioning installations, states that he secures the hest results when the shaft mounting is so arranged that the inner race of the hall bearing is a tight fit on the revolving shaft, or if not, the hearing should be retained between the thrust shoulders by a locking means so as to prevent the inner race from moving on the shaft.

Fit of Bearing Races

The outer race should he mounted with a sucking fit so that it can move in its retainer and thus present various points on the surface to action of the load. Also, the outer race should be mounted in some hard metal, such as malleahle iron or steel, especially if the case of the gearset is aluminum. When the bearings are mounted to take any considerahle end thrust, the surface which takes this thrust should be hardened as much as possible, and also of a fairly high carbon steel, or else case hardened. There is a slight creeping action of the races and also a hending action when the bearings are used in differentials. This gives a tendency to wear down the thrust collar against the hearing race—referring to the collar against the inner race.

Russell Huff, chief engineer of Dodge Bros., states that the best results are secured where one race is allowed to float in its setting with the other held tightly against the shoulder. Fred Bizzants, of the Gramm-Bernstein company, says that all the hearings for his concern are pressed on to the shaft of the same size as the hore of the bearings. They are then secured with nuts castellated, and cotter pin fastened.

W. P. Chrystler agrees that the inner race should be a tight fit on the shaft; in fact, a light press fit, with the exception of the rear wheel bearing. The inner races of the latter are a hard push fit. All inner races, except the race of the primary shaft driving pinion bearing, are tightly clamped between suitable shoulders and nuts to prevent their creeping. The one exception is made a drive fit on the hub of the pinion. Regarding the fit of the outer races, he believes in a hard push fit. The races of the hub bearing and those of the forward hearing of the propeller shaft are clamped tightly. The others are free.

Lessons of Experience

Some lessons learned from actual practice are given by Mr. Biedermann. The hearing must be so arranged as to meet conditions of load, speeds and lubricant as recommended by the hearing manufacturer. All bearing manufacturers should issue very stringent instructions and data covering the entire route of the hearing.

It is necessary to guard against distortion of the races in the opinion of T. P. Chase, of the King Motor Car Co. Packing with sufficient luhricant will aid in this, according to his views.

J. W. Whitbeck of the Chandler Motor Car Co., states that he believes it important that either one of the races he allowed to float laterally to a small amount.

Some of the reasons assigned by manufacturers for the use of hall hearings in specific parts are as follows: Minimizing friction, small space of installation, freedom from attention, accuracy secured, easy assemhly, radial and thrust components, small amount of luhricant, uniformity of wear and adaptability for use in places where adjustahle bearings are impossible.

ACCESSORIES

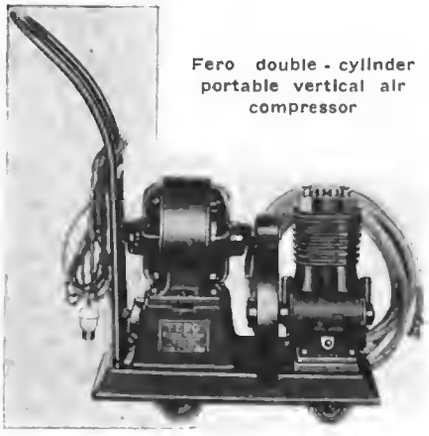
Fero Electric Air Compressors

THE Fero line of air compressors is designed to meet the needs of private and public garages and service stations, being made in portable and stationary form and in several sizes. The single-cylinder, horizontal stationary compressors driven by a ¼ hp. electric motor is suitable for garages housing not more than twenty cars. It may be advantageously used in connection with a 20-gal. air tank, together with an automatic switch or controller.

A double-cylinder, portable, vertical model for the direct inflation of tires, also operated by a ¼-hp. motor, displaces 1.8 cu. ft. of air at 500 r.p.m. with a pressure of 125 lb. per square inch.

A double-cylinder, portable or stationary vertical compressor with a 1/3-hp. or a ½-hp. motor is made for the direct inflation of tires in connection with an air tank.

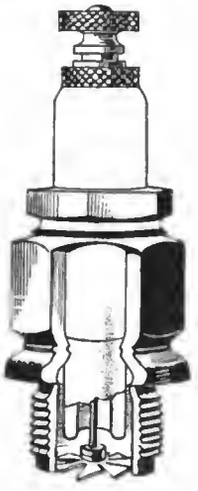
To the heavy-duty, double-cylinder vertical compressor is fitted a ¾-hp. motor of the repulsion type, which will start the pump against a tank pressure of 125 lb. and compress to 175 or 200 lb. tank pressure. Westinghouse alternating and direct current motors are used and electric controllers are furnished when desired for the stationary compressors used in connection with an air tank and not for the direct inflation of tires.—B. M. Fero, 509 Penwood Avenue, Wilkinsburg, Pa.



Fero double-cylinder portable vertical air compressor

Fan-Fire Spark Plugs

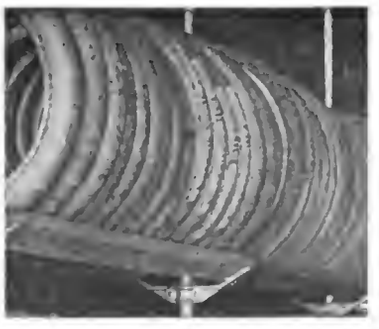
The feature of this plug is the use of a small fan-shaped member carried at the lower end of the central electrode. This fan is designed to rotate, due to the movement of the gases in the combustion chamber and thereby to prevent fouling of the spark gap. The spark jumps from the tips of the fan blades to the plug shell, the constant rotation presenting new surfaces opposite each other. The balance of the plug is of standard construction. Price, $1.—Fan Fire Spark Plug Co., Yonkers, N. Y.



Fan-fire spark plug. Note the revolving fan at the end of the central electrode

Effecto Finishes

Effecto is an enamel designed especially for automobile bodies. Only one coat is required and the composition is such that it will dry evenly and smoothly, no matter how carelessly it is applied. It dries quickly so that dust does not have much chance to settle. It is said to be durable, will not crack, chip off nor become dull to weather or through repeated washing. Effecto finishing varnish restores the original luster of the car and is of use when the original finish is shabby but not badly chipped or marred. Effecto top and seat dressing is designed to restore mohair and leather automobile tops, seats, side curtains, leather work, etc. It is a rich black. The dressing dries in about an hour. There is no danger that clothes will stick to the seats because it does not soften or become sticky, according to the manufacturer.—Pratt & Lambert, Inc., New York City, Buffalo and Chicago.



Elgin tire rack brackets enable the dealer to construct his own tire racks

Elgin Tire Rack Brackets

These brackets enable tire dealers to build their own tire racks. Upright standards of 1½-in. pipe are erected at about 6 ft. intervals, and the brackets are clamped onto the pipes. Planks are then screwed onto the brackets, making the racks continuous. In a 480 tire installation, 110 ft. of 1½-in. pipe and 33 brackets were used. The complete fixture cost less than $35. One dozen brackets are sufficient for a 150 casing rack. Price, $9 per dozen.—Elgin Motor Power Mfg. Co., Cedar Rapids, Iowa.

Major's Spring Lubricator

A combination dust boot and spring lubricator. It is a waterproof casing, lined with felt and laced over the leaves of the spring. The felt is saturated with oil, and the motion of the spring draws the oil between the leaves. All grit and water is excluded, it is said, and the constant supply of oil promotes easy riding and reduces spring breakage. Prices, per set of four, Ford, $12; runabout or five-passenger car, $20; seven-passenger car, $25.—Major Mfg. Co., 461 Pearl Street, New York City.

Superlustre Polishes

Superlustre polish is designed to clean the surfaces of automobile bodies thoroughly without injuring them in any way, leaving a glass-like finish on which dirt and dust cannot accumulate. By the use of this polish the manufacturer states that the car can be washed or used in rainy weather without ill effects.

The scratch and stain remover is intended to remove tar or grease stains and surface scratches on highly-finished bodies. It is claimed to restore the original finish when impaired by exposure or indiscreet methods in washing.—James J. Fero, Inc., 792 Seventh Avenue, New York City.

Showing the method of lacing Major's spring lubricator to the spring. The outside covering is a waterproof material and lined with oil saturated felt. The lubricator is said to keep all grit, water, etc., from between the leaves and furnish a constant supply of oil to the springs

Widening the Industry

THAT the manufacture of gas tractors is going to be a part of the automobile industry is just as certain as it is that the manufacture of trucks will remain one.

All self-propelling vehicles for use on surfaces other than steel rails can be classified together, and all such machines have difficulties to overcome which are identical throughout the whole range from the speedway racing car to the caterpillar type of gun hauling tractor.

It is easy to trace how the design of the motor truck has been based upon that of the passenger car, and it is beginning to be clear that the tractor is being based upon the truck. Really a tractor is nothing more than a special sort of a truck, working under rather harder conditions.

This being the case, it is rather remarkable that none of the big automobile manufacturing concerns have yet seen fit to enter the tractor field. Probably it is simply because they have been so busy with their other products that it was impossible to consider an extension, but the day when cars, trucks and tractors all come bearing the same brand is not far distant. There is room for almost as many sorts of tractors as there is for passenger cars. There is need for cheap machines and for the super-excellent also. A select few parts makers have seen the opportunity, but far fewer than seems reasonable; one misses from the tents at a tractor meet many names which could be there to their own advantage.

Engines, carbureters, magnetos, oils, greases, spark plugs and many other details are all wanted by tractor makers and tractor users. The manufacturers of these things have, so far, apparently been blind to the really huge business the birth of which is now in progress.

Kerosene Nearly Arrived

THE stimulus given to the use of kerosene in internal combustion engines on both sides of the Atlantic simultaneously cannot fail to have a great effect on the automobile industry. The rising price of gasoline in America has made it almost impossible to operate a tractor on the lighter fuel; many trucks are now running on kerosene, and devices are appearing which will function well in passenger car service.

In England government control of gasoline has almost shut off supply from passenger car users and has restricted the commercial vehicle supply greatly, so that a man must burn kerosene in his engine or allow his machine to lie idle. The inventive genius of two great engineering nations is thus concentrated on the one problem.

It is not an easy problem in many ways, but it is no harder than many others that have been solved, and there is reason to feel confident that the days of gasoline are numbered; at least for gasoline as the commonest automobile fuel. So many inventors are so near the kerosene carbureter that will do *everything* that can be done with gasoline that complete perfection cannot be far off. A little merging of patent interests, a little give and take between the inventors and a little really sympathetic interest on the part of motor car manufacturers are needed. Given these three things and the problem is solved. If the matter is not tackled promptly and squarely the European industry will steal another march on the American trade.

Temperature Control

ALTHOUGH the use of the thermostat for controlling the temperature of the cooling water in the cylinder jackets of automobile engines has now been applied to a good many thousand cars, there has been very little discussion concerning its merits. In a broad and general way these have been mentioned, but they have never been analyzed carefully.

Next Thursday the Detroit section of the S.A.E. will have a paper on the subject and will discuss the matter fully. It is an important matter, and is made all the more important by increasingly heavy fuel which is more susceptible to temperature changes. The author of the paper is an entirely disinterested individual who is well qualified to examine any scientific subject, so the meeting ought to get further forward with the subject than is the rule when an avowed protagonist of some system puts up his ideas to be criticised.

To Revive Giant's Despair Climb

Wilkes-Barre Club Applies for A. A. A. Sanction to Hold Event October 7

WILKES-BARRE, PA., Sept. 6—The Automobile Club of Wilkes-Barre, Pa., has requested the American Automobile Assn. Contest Board for a sanction for a hill-climb up Giant's Despair mountain just outside of Wilkes-Barre for October 7. According to present tentative plans there will be ten events, seven for stock cars and three for non-stock machines. This possibility of reviving this hill climb is a good indication of the increased interest in hill-climbs. With Pike's Peak in the Rocky Mountain district and Giant's Despair in the East the nucleus is formed for a series of hill-climbs which should greatly assist the speedways in maintaining interest in motor car events.

19 Indianapolis Race Entries

INDIANAPOLIS, IND., Sept. 4—Nineteen cars and drivers have been entered in the Harvest Racing Classic, which will be held on the Indianapolis Motor Speedway Sept. 9 as follows:

Car	Driver	Bore and Stroke	P.D.
Peugeot	Aitken	3.6x6.7	274
Peugeot	Merz	3.6x6.7	274
Osteweg	Osteweg	4.11/32x5	296.4
Sunbeam	Christiaens.	3.21x6.14	294.5
Premier	Lewis	3.6x6.7	275
Premier	Wilcox	3.6x6.7	274
Maxwell	Rickenbacher.	3.74x6.75	298.2
Duesenberg	Buzane	3.63/64x6	300
Sunbeam	Galvin	3.21x6.14	294.5
Maxwell	Henderson.	3.75x6.75	298.2
Duesenberg	Devlin	3.63/64x6	300
Duesenberg	D'Alene	3.63/64x6	300
Burman	Gable	3.⅝x7½	298
Kleinart	Klein	3.⅝x7½	298
Unnamed	De Palma	.....	....
Dans L'Argent	Muller	.....	....
Hoskins	Unnamed	.....	....
Rawlings	Unnamed	.....	....
Omar	Toft	.....	....

There are three events on the program: The 100-mile championship is the longest of the day. The other two events are the 50-mile and 20-mile dashes from a standing start.

Howard Marmon of the Nordyke & Marmon Co., Indianapolis, has been selected by the Indianapolis Motor Speedway officials to act as referee.

Ohio Speed-Trap Industry Hit

CLEVELAND, OHIO, Sept. 2—The automobile speed trap law in Ohio was dealt a heavy blow in an opinion which rules that township justices of the peace have no right to collect fines in speed cases. This opinion holds that peace justices do not have final jurisdiction in speed cases.

Owen Magnetic 4-Day Tour

NEW YORK CITY, Sept. 2.—The second annual Owen Magnetic tour will start from this city Sept. 9 and will embrace a four-day trip through the Berkshires and the White Mountains. A dozen or fifteen cars provided by the company will carry over fifty invited guests. The route will include Pittsfield, over the Mohawk Trail to Greenfield, first night; thence along the Connecticut Valley to Hanover, N. H., for lunch and to the Profile House, White Mountains, for the night. The third day will be to Boston and the fourth back to New York.

$100,000 Speedway Planned for Denver

DENVER, COL., Sept. 2 — A $100,000 speedway for automobile races is being planned by the Colorado Springs Athletic Club, which expects to push the project through by next summer. Among the promoters of this new enterprise for the Rocky Mountain region are Spencer Penrose. Charles MacNeil and other millionaire sportsmen who financed the building of the $250,000 highway to the summit of Pike's Peak and conducted the recent hillclimb over that highest road.

Milwaukee Dealers' Tour Ends

MILWAUKEE, WIS., Sept. 2.—The Milwaukee dealers to-day concluded their second annual State-fair-boosting tour of Wisconsin. Between Monday morning and this afternoon they traveled 555 miles, visited forty-four cities, villages and hamlets, and took the message to a territory of 1,000,000 people.

Weston Leaves U. S. Tire to Join Mitchell Motors

NEW YORK CITY, Sept. 2.—J. C. Weston, general sales manager of the United States Tire Company since 1914 and connected with that company since its inception, has resigned to become vice-president in charge of the sales of the Mitchell Motor Company, Racine, Wis. He thus takes up the duties of O. C. Friend, former sales manager of the Mitchell-Lewis Company, who resigned last July to become vice-president and general manager of the United Motors Company.

Mr. Weston has been in the tire business since 1896, when he became a salesman for Morgan & Wright. In 1906 he became secretary of the company and stayed with it when it became a member of the United States Tire Company. At that time Mr. Weston's duties were confined to the Pacific Coast district, which he organized. From there he took charge of the central district in Chicago and in 1913 came to New York as head of the contracting department, handling all of the automobile makers' business. The next year saw him in the position he has just vacated.

Though no successor has as yet been named by the tire company, his former duties will be redistributed at the present time by President J. N. Gunn.

Armored Mack in Fast Run

Covers 325 Miles from N. Y. to Plattsburg at Average of 10.3 M.P.H.

PLATTSBURG, N. Y., Aug. 31.—L. Grinnel, wealthy rookie at the training camp here, in his Mack 2-ton armored car arrived at 10 o'clock last night, having made the 325-mile trip from New York City in 22 hr. 13 min. actual running time, after being on the road 31 hr. 24 min. Average road speed was 10.3 m.p.h., after subtracting 4 hr. 29 min. of minor road stops. Not including the night or meal stops actual running speed was 14.6 m.p.h. This performance was made in spite of four detours of some length and one run of 20 miles on the roughest sort of mountain road between Elizabethtown and Keesville. At this point the speed was only 9.4 miles per hour. Between Troy and Saratoga Springs the 30.1-mile run was made in 1 hr. 40 min., at a speed of 19 miles. The time of the entire trip, including night stop at Troy, was 41 hr. 31 min., in which time 325 miles were covered. There were nineteen stops other than for meals and sleep, but no serious mechanical trouble. The engine missed some and one of the Kelly sectional blocks on the right rear wheel was lost when the truck came near going off the road on a particularly bad detour between Rhinebeck and Hudson. The driver failed to get the low gear meshed in time on a bad hill, so the truck backed within a few inches of a deep ditch.

32 M.P.H. on Good Roads

Besides detours and bad stretches above Elizabethtown the roads on an average were excellent, but the many turns slowed the vehicle down due to the impossibility of seeing ahead and danger of meeting other cars on the narrow roads. Paced by a motorcycle, however, it made 31 and 32 m.p.h. frequently on good straight roads. The machine was built for Grinnel by the International Motor Company for use in a volunteer machine gun company he is organizing in New Bedford, Mass. Being a rookie at Plattsburg, he determined, on being notified that the car was completed, to run it up here and put it through maneuvers with the Englewood battery on the hike of the August camp now in progress. Lieutenant R. A. Osmun of the Coast Artillery Corps at Governor's Island, escorted the car on an Indian motorcycle. In the machine were Grinnel, H. F. Welch, engineering department International Motor Co., M. C. Horine, editor of *The Commercial Vehicle*, observer and S. A. E. representative, and W. J. Wright, driver. Fuel consumption was over 7¼ m.p.g.

$59,994,118 Profits for Ford

49,870 Employes on Payroll—$52,550,711 Cash on Hand and in Banks

(*Continued from page* 381)

payroll contains 49,870 names, this including the parent plant and all branches. Of this number, 27,002 are employed at Detroit and getting $5 a day or more, 14,335 at the eighty-four branches and assembly plants, and 34,485 is the total at the home plant. The home office force numbers 1,028.

The marvelous growth of the Ford cash balance in 5 years is indicated by the following table:

1912, cash on hand and in banks....$6,400,100
1913, cash on hand and in banks....13,225,710
1914, cash on hand and in banks....27,441,468
1915, cash on hand and in banks....43,788,151
1916, cash on hand and in banks....52,550,771

In the same period of years, the value of the materials and supplies on hand has jumped from $6,629,533 to $31,895,434, and the investment in plants from $2,596,115 to $17,293,293.

The balance sheet for the past fiscal year tells the story. It appears herewith in connection with similar statements for the past 5 years.

Coincident with the making public of its financial statement, the Ford company, through Henry Ford, made it known that work is to commence at once on the much-talked-of steel plant and blast furnaces at River Rouge, a suburb on the west side of Detroit along the river. For some time past the Ford company has been acquiring a large tract in this district, but this is the first positive assurance that has been given that work is to be commenced soon. Julian Kennedy, recognized expert on the design and construction of blast furnaces, has been retained by the Ford company to design and superintend the construction of two furnaces on the River Rouge property. It will take 134 acres of land to accomodate the down-river works, the location of which will make it advantageous for the big ore freighters to bring the ore down from the northern part of the state and from Duluth. Blast furnaces, docks, coke ovens, and other buildings of the plant will entail an initial expenditure of $3,500,000. Most of the work will be done by machinery in this modern steel and iron plant, and only about 500 men will be employed at first, according to Henry Ford.

Profit-sharing Pays

Mr. Ford made a very significant statement on the issuance of the financial report. He said, "If you expect a man to give you his time and energy, you must fix his wages so he will have no financial worries. It pays. Our profits this year, after giving our employees a big share in them, show that to pay good wages is the most profitable way to do business." This is one of the big secrets of Ford success.

"My ambition," says Mr. Ford, "is to employ still more men; to spread the benefits of this industrial system to the greatest possible number, to help them build up their lives and their homes. To do this we are putting the greatest share of our profits back into the business."

In the report no mention is paid of the contemplated output of cars for the coming year, but elsewhere it has been stated that the output of cars will be 750,000, and 250,000 of the new Ford 1-ton truck that is to come out about the first of the year.

Ford Motor Company's Balance Sheet for 1916, 1915, 1914, 1913 and 1912

	1916	1915	1914	1913	1912
ASSETS					
Cash on hand and in banks...	$52,550,771.92	$43,788,151.23	$27,441,468.79	$13,225,710.82	$6,400,100.66

*The 1915 statement represents the business for only 10 months because last year it was decided to change the end of the fiscal year from September 30 to July 31.

FORD STATISTICS

Total output 13 years, 1,406,997 cars.
Employed 311 men first year.
Total of employees at home plant now, 34,489.
Total of employees, all plants, 49,870.
Total of employees getting $5 a day or more, 36,626.
Largest one-day output, 2,430 cars, Feb. 29, 1916.
Sales value of 1916 output, $206,867,347.47.
Sales value of 1903-1904 output, less than $2,500,000.

PRODUCTION FIGURES

Year	Cars Made and sold	Increase or Decrease	Daily Average
1916	533,921	plus 225,708	1816
1915	308,213	plus 59,906	1027
1914	248,307	plus 83,855	827
1913	164,452	plus 95,908	545
1912	68,544	plus 30,078	228

532 Maxwells Built in 1 Day

Average Production 400 Cars Daily—120,000 Cars for 1916-1917 Year

DETROIT, Sept. 5—A record was made by the Maxwell Motor Co. on Aug. 26 when 532 cars were turned out by the big plants here. The previous record was made only the day previous, when 501 cars were turned out. The average production of the big Oakland Avenue assembly plant is now about 400 cars per day, as compared with a maximum daily output 1 year ago of about 200 machines.

All Maxwells are assembled here, while most of the parts are manufactured in the concern's factories at Dayton, and Newcastle, Ind. These units are now making for the Detroit factory some 400 units daily, to keep pace with production.

It is stated that the 1916-1917 year will see 120,000 Maxwells built, as compared with 60,000 for the year just ended.

Morgan Appointed Abbott President

CLEVELAND, OHIO, Sept. 2.—G. W. Morgan, of the Mitchell Motor Car Co., Racine, Wis., has been appointed president and general manager of the Abbott Corp., this city. He succeeds C. L. Lewis, who recently retired as president.

Toft's Omar, Vail'a Hudson and Merz's Peugeot in a brush before the grandstand in the 300-mile Labor Day race on the new Cincinnati speedway

Aitken Wins at Cincinnati

Peugeot Makes 300 Miles at 97.06 M.P.H.—D'Alene Finishes Second

Car	Driver	Time	M.P.H.
Peugeot	Aitken	3:05:27.22	97.06
Duesenberg	D'Alene	3:09:56.00	95.05
Sunbeam	Galvin	3:18:35.58	90.06

CINCINNATI, OHIO, Sept. 4.—Driving at more than 97 m.p.h., J. D. Aitken won the 300-mile Labor day race on the new $750,000 Cincinnati Speedway before 27,000 spectators. D'Alene was second and Galvin third. Gil Anderson, in a Stutz, drove too close to the inner wall, crashed into it, and both he and his mechanician were badly hurt, Anderson sustaining injuries to his spine and a broken leg and arm.

It was confidently expected that Resta would win the race, in view of his previous victories on speedways all over the country, but he was forced out.

At the end of the first hundred miles Resta was averaging 100.55 m.p.h., and he did not stop until the end of the 168th mile, when he had a lead of 1:22 over Aitken, who was second.

George Buzane, in a Duesenberg, was fourth in 3:23:19; Art Klein, in a Crawford, was fifth, time 3:34:15; Devlin finished sixth in a Duesenberg in 3:46:06. Haibe's Kleinart was flagged at 270 miles and given seventh money, being the only car running at that time, although there were ten prizes to compete for.

Resta Takes the Lead

Resta took the lead in the first lap, closely followed by De Palma, and while the Mercedes lasted these two rivals fought for position. Resta was headed by De Palma at the end of 8 miles and held his position two laps, then gave way to Resta for one lap, taking the lead again for three laps, Resta taking the lead at 10 miles and De Palma going out with a broken connecting rod at the end of 22 miles, Aitken moving up to second place. Mulford's Peugeot was third and Wilcox's Premier fourth at the end of the 28th mile.

Flying start of the 300-mile race on Cincinnati speedway. There were 27,000 spectators

Resta and Aitken ran one-two until 165 miles were reached; then Aitken took the lead and held it until the finish, although there were times when his margin was very narrow. By the time 200 miles were covered Resta had taken third place, D'Alene holding second. There was a constant fight between Resta and D'Alene for second place, reversing once or twice every 20 miles until Resta went out at 288 miles with an overheated motor due to a balky radiator. Resta made four stops, but only changed one tire, which shows how his car was going.

With a field of twenty-eight cars it is surprising that so few finished. The speed during the early part of the race was around 105 miles per hour, but the terrific pace told on engines and tires. One by one cars dropped out, the majority of them with broken rods or burned bearings, which seems to indicate that the track is faster than the cars could stand. Nine cars had not made any stops until they went out.

As to tires, the track seemed fairly easy, only thirty casings having been changed, or an average of a little over one to each car starting.

Buzane a Surprise

Buzane, who took fourth money, was a surprise. He was a last-minute qualifier. His car was wrecked at Kalamazoo a week ago, and it was only by night and day work that he got it rebuilt. He reached the track at noon Sunday, fitted a new block on his motor and qualified late in the afternoon, just before the final limit given.

It is felt that Anderson's accident might not have happened had he had sufficient rest. He burned out a center crankshaft bearing in practice Saturday and had to go to Indianapolis to get another. He practically tore his car down last night and worked on it nearly all

*Six cylinders; all others four cylinders.

Infield at the new $750,000 speedway at Cincinnati during the 300-mile race which marked its inauguration on Labor Day. Note the parking of the cars in which a good share of the 27,000 spectators came to the track

night. D'Alene asked for and was given No. 13, and it seemed to have a charm, his winnings for to-day being $6,000.

Aitken won $12,000 and an extra $1,000 for leading at 200 and 250 miles. Resta got the Gibson trophy given by the Hotel Gibson for being first at 50 miles and $500 for being first at 100 miles. Galvin won $3,000, Buzane $1,500, Klein $1,300, Devlin $1,200, and Haibe $1,100. Haibe was overcome by the heat and Art Klein relieved him after having finished in a Crawford, thus winning two prizes in one race finished by two cars.

Planked Speedway

The 2-mile speedway is built on a tract of land 1 mile long and 1½ miles wide near Sharon, Ohio. Two-by-four planks are used and are laid lengthwise. This construction continues up at an angle of 90 deg. on the turns, thus making a safety rail with no breaks. The course is similar to New York's so far as the curves being part of a parabola.

35,000-Car Gain in Wisconsin

110,350 Cars and Trucks Registered Up to Sept. 1—353 More Dealers

MILWAUKEE, WIS., Sept. 4.—On the morning of Sept. 1 the report of private owners' registrations showed that 110,350 cars in the hands of private owners have been registered and licensed since Jan. 1. On the same day a year ago, the total was 75,600, showing a gain of nearly 35,000 cars for 1916. At this point last year the gain was 25,500 over the corresponding period of 1914.

20,559 More Than in 1915

On Sept. 1, Wisconsin registered 20,559 more cars than the total for the entire year 1915, which was 79,791. The gain represents more cars than were registered in Wisconsin during the entire year of 1912, when 24,578 cars were licensed. Likewise, it comes close to the total registration of 1913, which was 34,646.

The decided increase in the number of dealers is a feature of the situation in Wisconsin. In 1915, the state licensed 1,583 dealers. This year, up to Sept. 1, the number was 1,936, a gain of 353. Inasmuch as the practice of using dealers' licenses on privately-owned cars has been almost wholly discouraged, the license figures would indicate that Wisconsin has nearly 2,000 automobile dealers at this time, or just twice as many as it had in 1912.

Comparative figures on Wisconsin registration follow:

	1912	1913	1914	1915	To Sept. 1, 1916
Cars....	24,578	34,646	53,160	79,791	110,350
Dealers..	1,052	1,393	1,202	1,583	1,936

Over 16,000 Registrations in N. H.

CONCORD, N. H., Sept. 1.—Automobile owners will pay into the State treasury this year upwards of $325,000. Up to date the fees have run above $300,000, while last year they reached $257,000. More than 16,000 cars have been registered this year and about 1600 of them, or 10 per cent, are those of non-residents. Last year visiting motorists paid more than $15,000 into the State treasury. As September and October are good touring months many more visitors are expected here, and as the limit is but 10 days for them the fund is bound to swell.

Maine Registrations Increase 5534

AUGUSTA, ME., Sept. 1.—Maine is going to get a large revenue from the motorists this year. A few days ago the receipts had totaled $341,367.75. For the entire year of 1915 the state received $271,987, so the present total is $69,380.75. If the cars continue to increase the state will get at least $100,000 more than a year ago. The following table shows the increase up to Aug. 1:

	Jan. 1, to Aug. 1, 1915	Jan. 1, to Aug. 1, 1916	Increase
Automobiles	21,374	26,172	4,798
Trucks	1,098	1,834	736
Operators licensed	26,658	32,106	5,448
Dealers	324	305	*19

*Decrease.

180,000 Cars in Mo.

ST. LOUIS, MO., Sept. 4.—At the end of August, 180,000 automobile licenses had been issued by the state, more than 25,000 in excess of the total of last year. Of these, 19,453 were in St. Louis, 11,954 were in Kansas City.

U. S. L. Directors Elected

BUFFALO, N. Y., Sept. 1.—At the recent annual meeting of the stockholders of the U. S. Light & Heat Corp., the following board of directors were elected: E. H. Gold, J. A. Smith, R. C. Caples, H. W. Farnum, A. H. Ackerman, C. L. Lane, K. H. Addington, J. A. Roberts, Conrad Hubert, G. G. Shepard and E. K. Gordon.

The corporation recently obtained nearly $3,000,000 of new automobile storage battery business and has greatly increased its floor space and facilities to care for this increased volume of business.

New York Gasoline Drops 1 Cent

Metropolitan District, Covering Long Island and Conn. Affected By Reduction

NEW YORK CITY, Sept. 5.—Gasoline prices in this city, Long Island, and Connecticut, have been lowered 1 cent a gallon wholesale to 22 cents by the Standard Oil Co. Texas gasoline sells at 23 cents wholesale. Quotations from the rest of the country are as yet unchanged, though prices are expected to drop on account of the large expansion in gasoline manufacturing capacity and the improvement in refining methods enabling a larger gasoline yield with a corresponding increase in the production of crude oil.

Market Prices Steady

NEW YORK CITY, Sept. 5.—Quotations on the automobile materials last week in this city were steady and strong with a brisk demand. Changes for the most part were unimportant. Aluminum has again risen to 60 cents a lb., and is still in large demand by the automobile makers. The steel market was steady with prices unchanged. Many of the manufacturers are now putting in their contracts for future delivery on steel. Tin has gone down to $38.75 per 100 lb., a loss of 75 cents. Copper prices are holding at the high rate of 28 cents a lb., with few buyers at that price.

Gasoline goes down 1 cent a gal. tomorrow in this city and the surrounding territory. The wholesale price will be 22 cents per gal., and consumers will pay 25 cents.

Tenth Market Report Issued

CHICAGO, Sept. 2.—The tenth edition of the National Used Car Market Report has been issued by the Chicago Automobile Trade Assn. The book is much the same as the ninth edition; zone 11, centering in Dallas, is still missing, the co-operation of dealers in that section not having yet been arranged.

The H-A-L and Liberty are new names. The Marion-Handley supplants the Marion. The Crow has been dropped but the Crow-Elkhart remains. There are 139 gasoline cars and fourteen electrics listed.

The Liberty, Madison and Saxon factories are now co-operating in the distribution of the report to dealers, making twenty-one car manufacturers.

The pocket edition accompanies the larger edition, containing in abbreviated form the data in the larger book. The form in both has been found satisfactory and has not been changed.

G. M. C. Features Securities

Rises 25 Points on Report of Financial Readjustment on Sept. 7

NEW YORK CITY, Sept. 5—The automobile and accessory securities were on the whole lower last week, though in good demand. General Motors featured with a net gain of 25 points for the week, its quotation on Saturday being 550. The directors of this company have considered a readjustment of the capitalization of the company and will take definite action on Sept. 7. Although details have not been completed, the plan which is now under consideration calls for the formation of a new corporation with a capitalization of $100,000,000. It is understood that five shares of new common stock for one of old will be given under the new financing plan. The preferred, according to the plan, would be exchanged either share for share, or possibly six shares of stock for five of the old issue. The new common shares would probably be of no stated par value.

Firestone a Cleveland Feature

Firestone Tire common on the Cleveland Exchange was also a feature last week, with a gain of 20 points, the stock rising to the record price of 1020. This company, it is stated, is about to declare a share dividend of 700 to 800 per cent. The capital is to be increased to $50,000,000. The rest of the tire issues were strong and steady, sharing the generally buoyant tone which pervaded the securities market at large.

Goodyear common was unchanged at 240. Miller common sold at 220. Kelly-Springfield in a turnover of 24,000 shares rose 7⅛ points. It is rumored on the street that negotiations are being arranged for the merger of several of the large tire companies.

Dividends Declared

Stutz Motor Car Company initial quarterly of $1.25 a share, payable Oct. 2.

Chandler 2 per Cent Extra Dividend

CLEVELAND, OHIO, Sept. 6—An extra dividend of 1 per cent has been declared by the Chandler Motor Co., which has also declared the regular quarterly payment of 2 per cent both to be made Oct. 2 to stock of record Sept. 18. The company inaugurated dividends at the rate of 6 per cent last April and in July put the issue regularly upon an 8 per cent basis.

Bowser Treasurer Resigns

FORT WAYNE, IND., Aug. 31—At a meeting of the board of directors of S. F. Bowser & Co., Fort Wayne, the resignation of C. A. Dunkelberg as treasurer, to become effective Sept. 1, was accepted and W. G. Zahrt was elected to succeed him. Mr. Dunkelberg has been connected with the company for 17 years and Mr. Zahrt for 12½ years.

Firestone Stock $50,000,000

May Declare 800% Stock Dividend—To Retire Preferred at 110

AKRON, OHIO, Sept. 4.—The Firestone Tire & Rubber Co. has called a meeting of shareholders for Sept. 30, to authorize an increase in capital from $4,000,000 to $50,000,000.

Of the new capital $10,000,000 will be 6 per cent preferred, of which $5,000,000 has been underwritten by banking interests. The other $5,000,000 will not be issued at present.

5 per Cent on Common

The present issue of $1,000,000 preferred will be retired at 110, and the present common stock issue of $3,000,000 will be increased to $40,000,000. Dividends on this new common will be at the rate of 5 per cent.

It is reported that a stock dividend of from 700 to 800 per cent will be declared. If this dividend is 700 per cent, the income return to the shareholder will be just double the 20 per cent now paid on the smaller issue.

Six years ago Firestone common was selling for $105 a share. By 1915 it reached $360 a share. During the panic period it dropped to $300 a share, but by July of last year had reached $510. Yesterday it sold for $1,050 a share, an increase of 900 per cent in six years.

King armored car undergoing tests for use with landing parties of marines. At the left, method of transporting by boat, and at the right, hoisting the car to the wharf

King Armored Car at Rock Island

After Tests at Fort Myer and at Sea Trials Are Continued

ROCK ISLAND, ILL., Sept. 5.—That government interest in military motors has not waned with the subsiding of the temporary excitement on the Mexican border is attested by the arrival at the government arsenal here to-day of the King armored car which was under test by the officers of the ordnance department at Fort Myer, near Washington, D. C., recently. With its arrival at Rock Island, the land battleship completed another of the series of strenuous trials through which it is being put.

A Reliability Test

The present test is for the purpose of determining the reliability in overland trips and began in New York, Aug. 29. It was under the supervision of F. E. Edwards, chairman technical committee of the American Automobile Assn., H. A. Tarantous, New York, and Darwin S. Hatch of *Motor Age*.

The armored car was accompanied also by Capt. W. A. Ross, who has been with the military cars of the Allies in Europe and now is connected with the Armored Motor Car Co., Detroit, Mich. The ordnance department had a representative on board.

The miniature scout cruiser for land fighting is almost completely covered with ¼-in. armor plate and carries a revolving turret in which is mounted a machine gun. In action, it carries three men, a driver, mechanic and gunner, the latter revolving with the turret. When not in action three additional men can be carried comfortably outside. It is arranged to be completely inclosed in action, doors even closing over the radiator, so that with the exception of the wheels, no vital parts are exposed to fire. Small slits in the armor plate give vision to driver and gunner. Three sources of gasoline supply are provided, all within the protective covering, thus assuring a supply of fuel, even though the main tank should become damaged. The main tank in the frame feeds by suction to the Carter tank, and two others holding 4 gal. each, feed by gravity. The body is the design of Captain Ross and was built by the Armored Motor Car Co., Detroit, Mich.

It is mounted on an eight-cylinder King chassis, which, except for the dual wire wheels and tires in the rear and the wire wheel in front, is standard King production. Equipped with the armored body the car weighs 4600 lb., a figure considerably less than the weight of the armored cars now in service of the United States government.

Some of the other features of the car and its equipment are of particular interest. The body is constructed in units so that it can be taken apart for handling very easily. Two bridges, each 12 in. wide and as long as the whole car are mounted, one on either side of the body so that they serve the purpose of mud guards as well as for crossing ravines or loading on freight cars, barges, etc. At present these bridges are wood with steel trusses.

Hupmobile Capital-to-Capital Car Climbs Fort George Hill

NEW YORK CITY, Sept. 1—The Hupmobile model N touring car which is traveling from State capital to State capital, paused here long enough yesterday to give a demonstration of hill-climbing ability on Fort George hill. The car, driven by C. E. Salisbury, climbed the hill on high gear under the sanction of the American Automobile Assn. The hill is about 400 yd. in length and has a gradient of between 11 and 12 per cent all the way up. It is surfaced with Belgian block giving a very difficult road for traction, and is locally well known for its steepness. The test was under the supervision of J. Edward Schipper as technical representative of the A.A.A. The car left here for Hartford, Conn., to-day, after which other New England State capitals will be visited.

Hupmobile capital-to-capital car climbing Fort George hill in New York City under the supervision of the A. A. A.

Factory Miscellany

Indianapolis Parts Co. Builds—The Metal Auto Parts Co., Indianapolis, Ind., will build a plant costing $60,000.

Schwarz Wheel to Enlarge—The Schwarz Wheel Co., Philadelphia, Pa., has purchased 6 acres at Holmesburg, near its present plant, for extensions.

Philadelphia Machine Co. Builds—The Tinius Olsen Testing Machine Co., Philadelphia, is having a four-story factory building erected at 1210-12-14 Nectarine Street.

Claus Cock Co. Builds—The Claus Automatic Gas Cock Co., 2601 Vliet Street, Milwaukee, is building a new plant, 81 by 149 ft., at Franklin and Booth Streets, to be ready Oct. 15 or Nov. 1.

Makes Special Paint for Automobile Parts—The Shepard Paint Co., Columbus, Ohio, is placing on the market specially prepared paint for the protection of automobile parts, in addition to its regular line of paints.

John Brown Co. Installs Electric Ovens—The John W. Brown Manufacturing Co., Columbus, Ohio, maker of automobile lamps and accessories, has installed a series of electric ovens, which will double the capacity of the plant.

Piston Ring Co. Builds—With its new four-story factory building practically completed, the Piston Ring Co., Muskegon Heights, Mich., has started the installation of machinery. A machine shop of the latest description will occupy the greater part of the new building.

Delay on Falls Motor Addition—Some delay is being encountered in the commencement of work on the new assembling shop and repair shop for the Falls Motors Corp., Sheboygan Falls, Wis. Bids received early this week for the work were rejected and a new call issued. Figures closed Sept. 1 under the new request.

Makes Spring-Tempering Furnace—The Railway Materials Co., Stevens Point, Wis., has opened a new department which will manufacture fuel oil furnaces for tempering vehicle springs and steel forgings. Equipment is now being installed and a large production is being arranged for to fill the big volume of orders already in hand.

Partridge Rubber Buys Guelph Plant—The Partridge Rubber Co. of Montreal, Que., has bought the business and plant of the Standard Tire & Rubber Co., Guelph, Ont. The purchase price was in the neighborhood of $150,000. The company expects to give employment to 150 hands at the outset, and the expectation is that this number will be increased. The new concern takes over all the contracts of the Standard people.

Briggs & Stratton Build—The Briggs & Stratton Co., 258 Milwaukee Street, Milwaukee, Wis., one of the largest manufacturers of ignition and automobile specialties in the Middle West, has started work on the erection of a new plant costing in excess of $100,000. A new location, Hopkins and Center Streets, has been chosen. The main building will be five stories high, 60 by 220 ft. in size, and of strictly fireproof construction.

Perfection Tire May Build at Niagara Falls—The Perfection Tire & Motor Co., Ltd., manufacturer of automobile tires and mechanical rubber goods, will erect a factory in Niagara Falls, Ont., providing the ratepayers ratify a by-law which will be presented to them in a few weeks. The by-law provides that the city furnish the company with power at $10 a horsepower for a period of 10 years, also give the company a fixed assessment for this time.

Cleveland Factory Items—The National Acme Manufacturing Co., Cleveland, Ohio, has purchased 15 acres of land at East 131st Street and the Belt Line, where an additional plant will be located, as no more land could be secured on Stanton Avenue adjoining the present factory. The deal involved about $100,000.

The Bondy Manufacturing Co., maker of automobile tops, has arranged to lease for a term of 20 years a building that will be erected on Carnegie Avenue, just west of the Packard-Cleveland Co.'s new building. The width of the ground is 50 ft.

The Big Four Tire & Rubber Co., with offices in the new Guardian Building, has purchased the old plant of the Ohio Rubber Co. at Berea, a few miles south of this city. It will be equipped and in operation within 60 days, if present plans are carried out.

The Week in the Industry

Hartford Trade News—F. G. Robins, Autocar distributer, Hartford, Conn., has removed from 522 Asylum Street to 45 Ann Street to the quarters recently vacated by the Chalmers Auto Agency.

Wells Wetherell, formerly of the firm of Kingsbury & Wetherell, has severed his connection and joined Frank G. Robins, Inc., taking with him the representation of the Saxon.

The Overland-Hartford Co. has removed the parts department from the towntown salesroom to the temporary service building on Lawrence Street, formerly the Billings & Spencer Co. machine shop.

D. A. Thrall, Ollie Thrall, E. H. Richardson and C. M. Colton have formed the Thrall-Colton Motor Car Co. and have taken quarters at 1283 Main Street. The firm will represent the Kissel Kar. C. M. Colton until recently was associated with the Colonial Auto Co. at 1270 Main Street.

St. Louis Items—R. W. Immasche, St. Louis, until recently distributor of the Stutz cars in this territory, has accepted the agency for the new Jordan car. He will open temporary showrooms at 4130 Olive Street.

The Dorris Motor Co. will open showrooms on Locust Street, for the first time taking a place on the Row. The former Chevrolet showrooms at the Locust-Lindell cutoff have been leased from the Chevrolet Co. of Missouri, Inc., which took over the distribution from the Triangle Motor Co.

C. B. Hollister has been promoted by the Efficiency Oil Co. and has charge of the company's plant at 2100 North Kings Highway. C. C. Thurston becomes sales manager at the branch at 3219 Locust.

Curtis Van Antwerp has been placed in charge of the service department of the Supreme Motor Co. Tom Herbert, formerly salesman for the Peerless distributor, has joined the force of the Supreme Motor So.

Packard Missouri Motor Co. has opened used-car showrooms in the recently leased building at Eighteenth and Pine Streets. E. Dillard, a newspaper man, is in charge.

Broadway Motor Co. has leased showrooms at Broadway and Cass Avenue for a Ford agency.

Tevis Motor Co. has leased 3118 Locust for a Ford agency.

Ohio News Items—L. C. Bailey, formerly manager of the Toledo-Mercer Co., Toledo, has been made sales manager of the George E. Wert Co., northwestern Ohio distributer for the Marion and Briscoe.

F. M. Bonner & Son is the name of a new concern at 21 East Walnut Street, Columbus, to handle and rebuild Fords.

The Commercial Motor Sales Co., 411 West Spring Street, Columbus, is the name of a new concern organized to handle Bessemer trucks in central Ohio territory.

The Broad & High Auto Supply Co. is the name of a new concern at 43 West Broad Street, Columbus, to handle supplies. It is operated by W. M. Borrow & Co.

The Blair Motor Truck Co., Newark, has opened an agency in Columbus under the name of the Blair Motor Truck Sales Co., located at 60 East Spring Street.

Oscar Lear Motor Car Co., Columbus, has solved the problem of disposing of used cars by holding an auction of second-hand machines. The offer was made that if the purchaser was not satisfied after trial the money would be refunded.

The Laurence Motor Co. is the name of a new concern organized at 165 North Fourth Street, Columbus, to handle Republic and Vim trucks in nine counties in central Ohio. Y. B. Jones is general manager. It is the intention to operate a service department in connection with the sales department.

In order to relieve the increasing congestion in the down-town business section of Columbus, C. L. McKee, a broker, plans the erection of a five-story fireproof garage at Fourth and Spring Streets to take care of cars during business hours. There is a strong agitation to prevent parking of automobiles on the downtown streets, and the plan is to provide a place for cars, which will be forced off the streets. In anticipation of the passage of an ordinance preventing parking of cars, many available sites are being optioned for the purpose of erecting garages.

Toronto Items—G. C. Pearsall, connected with the Russell Motor Car Co., Toronto, has been appointed Canadian distributer for the Scripps-Booth.

The Mutual Motors, 960 Gerrard Street, East Toronto, Ont., has been selected as Ontario representative for Marion-Handley cars.

Wis. Trade Happenings—J. C. Heitman, Sparta, has taken the agency for the Pathfinder in a large territory in western Wisconsin, including La Crosse, and has established headquarters in the M. Savage & Co. garage, 419 State Street, La Crosse.

E. A. Glab has retired from the Enger Motor Sales Co., Milwaukee, and will devote his entire attention to the Pathfinder Sales Co., 163 Eleventh Street, Milwaukee, of which he is president.

The Overland-Green Bay Co., Green Bay, northeastern Wisconsin distributer for the Overland-Wisconsin Co., Milwaukee, state agent, has awarded contracts for the erection of its branch house at Pearl and Walnut Streets, Green Bay. It will be 100 by 120 ft. in size, two-story and basement, and of fireproof construction. The Overland-Wausau Co., another subsidiary recently formed, is building a three-story branch house, 60 by 120 ft., at Wausau, to serve central Wisconsin.

The Milwaukee Auto Sales Co., Seventh Street and North Avenue, Milwaukee, is state distributer of the Briscoe and the Detroiter Six.

W. F. Schroeder, Platteville, has been appointed Mitchell dealer in southwestern Wisconsin territory.

Philadelphia Items—The Biddle Motor Car Co. of Philadelphia has opened an export office in Whitehall Street, New York, and is now shipping cars to foreign countries. The company has a number of models, but specializes on none. President Maris states that a change of policy is being considered and that next year the cars will be sold through dealers. More expensive bodies will be used.

The Smith Form-a-Truck Sales Co. of New York has opened a Philadelphia branch and service station at 2121 Vine Street. W. H. Durphy has been appointed district manager.

C. J. Rogers, of the Rogers-Sargent Motor Co., 202-204 North Broad Street, Philadelphia, was appointed by the manufacturers of the Lexington automobile Eastern representative, in charge of the sales in this State, New Jersey, Delaware and Maryland. Mr. Rogers will retain his office in the Lexington agency here.

The Philadelphia Gear Works, 1120 Vine Street, is erecting a tool house addition adjoining its plant.

The Chester County Motor Co., Coatesville, Pa., has leased a two-story building at 5740 Cherry Street, Philadelphia which will be used as a garage and service station.

The Belmont Garage, Forty-fourth Street and Parkside Avenue, has taken the agency for the Dixie automobile, made by the Dixie Motor Co., Louisville, Ky.

VOL. XXXV NEW YORK—THURSDAY, SEPTEMBER 14, 1916—CHICAGO NO. 11

Maxwell Earnings Gain 135%

Car Sales Increase 88% Over 1915—Can Make 100,000 Cars Per Year

NEW YORK CITY, Sept. 13—Maxwell earnings have increased 135 per cent over last year and 260 per cent in the last 2 years, according to the annual statement issued by Walter E. Flanders, president of the Maxwell Motor Co., Inc., to the stockholders. The surplus earned in the last year was equivalent to 30 per cent on the common stock after allowing 7 per cent on the first preferred and 6 per cent for the second preferred. The report states that the surplus earnings after a deduction of $500,000 for depreciation were $5,426,000.

Net Assets $11,176,783.26

The net working assets of the company and its subsidiaries at the close of its third fiscal year are $11,176,783.26, an increase as compared with the close of the second fiscal year, of over $3,500,000 and an increase as compared with the close of the first fiscal year, of over $5,000,000.

Cash on hand is $3,269,552.50 as compared with $2,652,628.60 at the close of the second fiscal year, and $1,175,992.68 at the close of the first fiscal year.

The inventories have been taken on most conservative lines, without any element of profit due to advanced prices for materials purchased under favor contracts.

The number of cars sold by the Max-

August a Record Month for Paige

DETROIT, Sept. 8—For the month of August just closed, the Paige-Detroit Motor Car Co. established a new record for volume of business done. Although August is not generally regarded as a big month with automobile manufacturers, nevertheless Paige transacted in the 31 days $2,020,000 worth of business, which is the greatest month's showing in the concern's history.

In making this announcement, Paige points out that the figures quoted do not tell the whole story, however. The demand for immediate shipment was much larger than the total volume of business would indicate. It was necessary to hold up orders for 1982 cars, and place the delivery of these in September. It is believed that the present month will even exceed the August record.

—

Willys-Overland Capacity for 1917 Is 300,000

TOLEDO, OHIO, Sept. 12—By the end of the present year the Willys-Overland Co. will be in position to manufacture 300,000 cars annually, according to a statement by John N. Willys, president of the company.

The total outlay for this construction and additional equipment will be less than $5,000,000 and will terminate, temporarily at least, the company's policy of expansion, which has made Overland the second largest car manufacturer in the world.

From this time on, Mr. Willys states, the energies of the organization will be devoted to reducing costs, increasing efficiency and improving production.

The recent sale of 600,000 shares of common stock has placed the company in such financial position that no further increase in preferred or common will be required for its expansion. The statement of assets and liabilities as applied to the balance sheet of June 30 last, shows that upon payment for the new stock, the company will have more than $20,000,000 cash on hand and more than $25,000,000 of other quick assets.

Mr. Willys owns a majority of the common and states that it is his intention to continue personally to control and direct the affairs of the company.

United Motors Corp. Buys Klaxon

Sixth Accessory and Parts Concern To Be Merged—McConnell President

NEW YORK, Sept. 12—The Klaxon horn business has been taken over by the United Motors Corp., which was formed several weeks ago as a merger of five parts companies. The Lovell-McConnell Mfg. Co. of Newark, N. J., which built the horn business, will become the Klaxon Co. and F. Hallett Lovell, Jr., president and principal owner, will retire from active connection with the company, although he will remain a director.

The Lovell-McConnell plant will be doubled at once to provide for increased production. Simultaneously with the consummation of this merger, comes a statement from the Willys-Overland Co. that it will discontinue the manufacture or horns and will close a contract with Klaxon for a term of years.

Contracts are also being executed for the use of the Klaxon horn on the Cadillac, Buick, Oldsmobile, Oakland, Scripps-Booth and Chevrolet. It is used on many other cars.

D. A. McConnell, who has been vice-president since the concern was organized, about 9 years ago, will become president; Otis C. Friend, who recently retired from the Mitchell to join the United Motors, will be the new vice-president, and Walter P. Coghlan, who has been secretary, will become secretary and treasurer. While Lovell will remain a director, his time will be chiefly devoted to other concerns.

The United Motors Corp. includes besides the Klaxon, the Perlman Rim Corp., Remy Electric Co., New Departure Mfg. Co., Hyatt Roller Bearing Co., and Dayton Engineering Laboratories Co., maker of Delco electric systems.

Ford Races Draw 10,000

Rebuilt Cars Average Well Over 60 M.P.H. on Chicago Speedway

CHICAGO SPEEDWAY, Sept. 10—Fords that looked like Fords and some that did not showed their speed proclivities today in the world's first Ford speedway race. If any of the 10,000 spectators came with any doubt as to rebuilt Fords doing a mile in a minute or less they went away with minds relieved of that feeling. They saw 20 miles run at an average of 62.83 miles per hour, 30 miles at 60.4, and 50 miles at 62.5 miles per hour, first honors in the former and latter going to Paul D. Harvey, Oak Park, Ill., whose car carried No. 1, and bore a striking resemblance to Dario Resta's blue Peugeot. Just to show that his car had some reserve speed, Harvey did a lap in the 50-mile event in 1 minute and 35 seconds, or at the rate of 72.5 miles per hour. This came immediately after he lost the lead at the end of 38 miles through a stop at the pits to change a spark plug.

Harvey's time for the 20 miles was 19 minutes and 6 seconds, and his average speed 62.83 miles per hour. Laznasky's time was 19 minutes 12.4 seconds; speed, 62.49. Jury finished in 19 minutes and 21.4 seconds, his average being 60.7 miles per hour. H. A. Wolf, Desplaines, Ill., was fourth in 20 minutes and 44.2 seconds; speed, 57.87 miles per hour. The others were flagged. Harvey won $125; Laznasky, $75, and Jury, $35.

The Illinois Championship

The second race of the afternoon was for the Illinois State championship, limited to Illinois entries only, and was for 30 miles. Eight cars started and stellar honors went to B. F. Davis, Paris, Ill., who turned the fifteen laps in 29 minutes 47.3 seconds. His average being 60.4 miles per hour. Only once did he give up the lead, Verne Abbott, Woodstock, Ill., heading him across the tape at the end of 26 miles. He regained his position, however, before the next lap was completed and finished 6.3 seconds ahead of Abbott, whose total time was 29 minutes 53.6 seconds, an average of 60.2 miles per hour. Third place went to P. F. Walter, Merrillville, Ind., in 32 minutes and 36 seconds, a speed of 55 miles per hour.

Harvey led throughout the 50-mile race except for the one lap as mentioned previously. Davis was a close contender up to 32 miles and it seemed to be a toss-up between them until a broken connecting rod put the Paris (Ill.) car out of the running. At 10 miles Harvey's time was 9:28:6; speed, 63.25; 20 miles, 18:39:6; speed, 64.25; 30 miles, 27:47; speed, 64.75, and his finish 48:10, speed, 62.5 miles per hour. Laznasky was second, in 48:08:6, and his speed was 61 miles per hour. Henry Mueller, Chicago, was third, his time being 52:35:4, and his speed 57 miles per hour. Peter F. Cordell, Oak Park, Ill., finished fourth, his time being 52:45:6.

The interstate championship, or 50-mile windup, carried a $500 first prize, $100 second and $50 third. Thus Harvey, by winning $125 in the first event and $500 in the final, won $625. He was the only entrant to win two prizes. How these cars were rebuilt is told on pages 465 and 466.

—

1917 Elcar at $795

NEW YORK CITY, Sept. 8—The 1917 Elcar, selling at $795, has been announced by the Elkhart Carriage and Motor Car Co., Elkhart, Ind. There are two body types, the Clover Leaf roadster, seating four passengers, and a five-passenger touring car.

The specifications include a long-stroke motor, 3½ by 5; unit power plant; three-point suspension; 114-in. wheelbase; full-floating rear axle; Delco ignition; full Turkish style upholstering.

—

Applications Now for Show Space

NEW YORK CITY, Sept. 13—Application blanks for floorspace and diagrams have been issued for the seventeenth annual automobile shows by the National Automobile Chamber of Commerce. They must be returned, filled out, by Sept. 30 in order that the applicants may participate in the drawing for the first allotment which takes place at the Chamber of Commerce headquarters on Thursday, Oct. 5. The New York show will be at the Grand Central Palace from Jan. 6 to 13. The Chicago show will be at the Coliseum and Armory from Jan. 27 to Feb. 3.

As usual, there will be two departments of the automobile section, which at New York will include the first and second floors of the Palace. There will also be wall space on the third and fourth floors. At the Coliseum and Armory the automobile section will include all of the main floors of both buildings. The remaining space will be devoted to accessories, parts, motorcycles, etc. The price per square foot is as follows: New York, $1.10 to $1.50; Chicago, 75 cents to $1.25.

—

White Co. to Erect Addition

CLEVELAND, OHIO, Sept. 11—The White Co. is to add a $200,000 building to its present manufacturing facilities. It will consist of a one-story concrete and steel structure 241 by 304 ft. This will be built at the northeast corner of the present plant.

Reo Truck and Car Combine

Directors Believe One Organization Better in Handling Increased Business

LANSING, MICH., Sept. 8—The Reo Motor Truck Co. and the Reo Motor Car Co. are to be formally consolidated by an exchange of the shares of the truck company for an equal number of shares of the car company.

According to an announcement sent out to-day to the stockholders of the two companies the directors of the Reo Motor Car Co., who are also directors of the truck company, after careful consideration, believe the interests of both corporations will be best served by such a move. The same executive, selling and office organizations have endeavored to handle the business of both, and up to this time the same motors and many parts manufactured by the Reo car company have been used by both companies. However, changes in design and further development of the business will make such an arrangement impractical, it is stated.

Increased business, it is pointed out, has correspondingly increased the difficulties in handling the affairs of the two corporations separately, and makes it impossible to secure the results that the directors are convinced can be obtained through one well-organized corporation and administration.

Administration Simplified

Accordingly, the Reo Motor Car Co. will purchase all Reo Truck stock delivered to the Capital National Bank, Lansing, or to Secretary D. E. Bates of the Reo Motor Car Co., on or before Sept. 20th, and pay for these shares with car stock.

The car stock has been selling on the Detroit Stock Exchange around $44 per share, and the truck stock some 5 points under it, but to-day the truck stock climbed to the same figure as the car.

Buys Three Blocks

A tract of land covering three city blocks located south of the Grank Trunk railroad tracks and extending to the Michigan Central tracks, have been purchased by the Reo Motor Car Co. Together with other land purchases made in that section of Lansing, the Reo company now has nearly half a mile of land along the Grand Trunk tracks. The purchases have been made to be prepared for further extensions of the plants of both the Reo car and the Reo truck companies, and it is not unlikely that the erection of new buildings will be started in the near future.

Motor Products Gets Lozier Plant

$1,000,000 Deal Gives Lozier Present Plant of Rands Mfg. Co.

DETROIT, MICH., Sept. 8—A deal said to involve a $1,000,000 consideration has been closed here between the Motor Products Corp. and the Lozier Motor Co., whereby the large modern plant of the Lozier company comes into the possession of the Motor Products Corp. The Lozier company does not go out of existence by this move, however, for it will take over the plant now used by the Rands Mfg. Co., one of the subsidiaries of the Motor Products combine.

The Lozier plant is a large group of up-to-date factory buildings located on Mack Avenue, on the west side of the city, and covering about 62 acres. There is an attractive administrative building in front of the factory structures, and a power plant for supplying ample power for all machinery. It was occupied by the old Lozier company prior to the reorganization, and has since been used for the manufacture of Lozier cars by the new Lozier concern.

Motor Products Corp. was organized in May of this year, with a capitalization of 100,000 shares of no par value, as a holding company for several large parts manufacturers located in Detroit and vicinity. The Rands Mfg. Co., maker of windshields, tops and steering wheels; the Vanguard Mfg. Co., specialist in windshield manufacture; the Diamond Mfg. Co., producer of automobile metal stampings; and the Universal Metal Co., maker of metal parts and possessing a large tube mill are all parts of the Motor Products Co. and located in Detroit. Besides these, the combine includes the Superior Mfg. Co., Ann Arbor, Mich., which is also a windshield and metal parts producer.

To Concentrate

The acquisition of the large Lozier works is the first step toward the concentration of the activities of the consolidation, and it is pointed out by one of the officials that the new plant will allow Motor Products to realize at once the fundamental purposes for which the company was formed. By means of this concentration in one plant, it will not only enable the concern to put in effect some great economies in manufacturing, but will enable the securing of managerial co-operation such as could not be attained while a number of plants were operating as separate units.

Motor Products is headed by well-known men in the industry. W. C. Rands is president; C. F. Jensen, vice-president; H. H. Seeley, vice-president; D. B. Lee, treasurer and general manager; M. L. Brown, secretary, and R. R. Seeley, director and production manager.

In addition to concentration in the new property it is the intention to make large additions to the tube mill to keep pace with a growing business, and to continue the Ann Arbor plant on special work, besides the expanding of the Walkerville, Ont., plant to care for an increasing Canadian business.

The plant that goes to Lozier, and up to this time has been occupied by the Rands subsidiary, was formerly the home of the Warren Motor Car Co., now out of business. Being constructed primarily for the making of automobiles, the Lozier people expect to effect economies in manufacture of their car. The buildings are of brick and occupy a site covering 6 acres. This property is said to be valued at $300,000. The cash received from the sale of the Lozier plant will be utilized as working capital by the Lozier concern, and plans for refinancing will bring new money into the business, according to Samuel Frank, secretary of the concern.

Watson Asst. to Haynes, Gen. Manager

KOKOMO, IND., Sept. 14—Don L. Watson, for the last year sales manager of the Haynes Auto Company, has been promoted to the office of assistant general manager, a newly created position. He will do a large part of the detail work in the general manager's office.

Davidson Resigns from Continental

DETROIT, MICH., Sept. 8—Wm. J. Davidson, of the engineering department of the Cadillac Motor Car Co., has resigned to take up other lines of activity in the industry.

Pike Heads Paige Efficiency Dept.

DETROIT, MICH., Sept. 8—The recently established efficiency and sales promotion department of the Paige-Detroit Motor Car Co. is to be managed by C. S. Pike, who comes from the sales department of the Burroughs Adding Machine Co., this city.

Batchelder Asst. Sales Mgr. of Dort Co.

FLINT, MICH., Sept. 8—C. F. Batchelder has been appointed assistant general sales manager for the Dort Motor Car Co., this city. He was for 10 years general sales manager of the John Deere Plow Co.

Bradley Is Paige Purchasing Agent

DETROIT, MICH., Sept. 8—Thomas Bradley, for 5½ years with the Paige-Detroit Motor Car Co., as assistant in the purchasing department, has been promoted to the position of purchasing agent, following the resignation of P. E. Stroup, former purchasing manager.

Harroun Cars by Show Time

To Make 25,000 Cars Next Year—Work on Design for 2 Years

NEW YORK CITY, Sept. 13—Papers will be filed to-morrow at Wilmington, Del., incorporating the Harroun Motor Corp. for $10,000,000, all common. Ray Harroun, well known as a racing engineer, and for his connection with the Maxwell racing team, has been working on this car for 2 years. The first car is now ready and there will be ten sample cars ready for the national shows in January. Production will start for dealers in March and by May 1 the organization is expected to be embarked on quantity production. It is planned that 25,000 cars will be made between May 1 of the first year and May 1 of the second.

Many Pressed Steel Parts

The car will be distinguished by a large number of pressed steel parts. It will sell for $595, and this low price will be met largely through the elimination of machine work by using the stampings. Such parts as the spring seats, brake, spiders, differential carrier, spring shackle, etc., will be manufactured in this way, thus cutting down labor to a minimum. While definite specifications of the car cannot be announced at the present time, it will have a four-cylinder high-efficiency motor with the valves probably in the head. The wheelbase is 107 in., and the first cars at least will have five-passenger bodies.

John Guy Monihan is president of the new organization. He was formerly with the Premier company and was later vice-president and general manager of the Marion. Ward Macy will be in charge of sales and Paul Bruske of advertising. The plant site will be located near Detroit.

DePalma Mfg. Co. Buys Plant

DETROIT, MICH., Sept. 8—The DePalma Mfg. Co., composed of Ralph DePalma and Frank Book, the latter a Detroit capitalist, have acquired a factory building on East Woodbridge Street for about $23,000, it is stated. The plant will be utilized for the manufacture of racing automobiles under the direction of the veteran driver, DePalma.

Kirkpatrick Is Hood Vice-President

DETROIT, MICH., Sept. 8.—W. H. Kirkpatrick, for 9 years head of the sales department of the Peerless Motor Car Co., Cleveland, has been elected vice-president of the Wallace C. Hood Service Bureau here.

ACCESSORIES In South America

No. IV

U. S. A. Tire Firms Should Become Strongly Established—Underinflation and Rim Cutting Main Troubles

By David Beecroft

ONE thing is certain, namely, that we should establish ourselves as strongly as possible to-day. Do not let us establish ourselves on shifting, uncertain sands, but on the bedrock of sound business. Sound business with South American houses is to give them our best prices, and is not to exact as high a price as we can get solely because competition is for the time cut out. It is expected that in a few months competition among U. S. A. tire firms may bring the price question to a legitimate adjustment.

Take a page from a day's conversation in tire repairs. One large supply dealer stocked up with a U. S. A. cement which cost him nearly 10 per cent more than the European cements he had previously handled. He could not get the European goods and had to take ours. He did not like paying a higher price for ours, but had to. As soon as he can get the European brands at the old prices he says he is going to. In the meantime is it not better business for our concerns to give lower prices where possible and cut the profits for the purpose of getting more firmly established? That is the way Germany got in so strongly. The Germans were willing to cut profits and get volume. We should to-day aim at the same objective.

Fancy Repair Cans

We need to put some of our tire repair goods up in more attractive cans. Europe can teach us lessons in how to put goods up in clean, business-looking tins. Several samples of our goods seen in two or three places had faded labels, and in others the labels were stained. From the buyer's viewpoint the goods looked old. Put yourself in the buyer's place. Walk into a supply house and see if clean-looking cans with clean labels are not attractive.

When goods come from a foreign country and from firms that we do not know much about our first impression of the goods is obtained from the way they are put up. If they are in clean, businesslike cans we are attracted. Our first impressions of those goods are favorable. We approach them with a fair feeling. If, on the other hand, the labels are stained or faded we approach them with mental uncertainty. We are not quite certain the goods are fresh. We think that some dumping act is being worked on us. Clean labels pay.

Some business questions will come up with regard to marketing tires in South America. Some of our concerns are already consigning stocks to certain large distributers. They find it necessary and they think it good business to do so and thus firmly establish themselves. In this way they are assured of always having a good stock on hand to distribute.

One or two other concerns that do not believe in consigning tires are giving their wholesale distributers very close prices and are giving 3 months' time and perhaps taking a few notes for longer periods. There is no reason why this cannot be done, because many of the large jobbers are just as reliable as any you can find in the U. S. A. With the National City Bank and its five branches and large credit departments in the five largest cities in Brazil, Argentina and Uruguay, there is not any difficulty with regard to credits. You can get any credit rating information you may desire. Dun's and Bradstreet's are also there. True, it takes a little longer time to get some of the credit ratings, but time is more of an element in all export business.

Tire Stocks

We told recently of how Michelin stocked heavily with his tires at several South American ports; of how he paid the import duties and of how he could make deliveries in a day or two to nearly any point in the different countries excepting those distant interior parts. We might also have told of the good business of the Michelin firm in having quantity contracts which when the dealer's sales reach a given volume within a year he gets an additional discount. This proved excellent business and is still proving excellent business with this enterprising firm.

The anti-skid rubber tire of our U. S. A. factories is more or less of a novelty to Buenos Aires and Brazil and to the citizens of many other cities. The European tire business consisted largely of the steel-studded tire that is used on one rear wheel and on the opposite front wheel. You see thousands of these in Buenos Aires and Rio, just as you do in London and Paris. A city ordinance in Buenos Aires required steel-studded equipment, so it was necessary for our tire dealers there to demonstrate before the traffic department of the city to prove the efficiency of the rubber-tread tire. This has been satisfactorily accomplished, and to-day there is no barrier to the sale of such tires.

Many Plain Treads

It is surprising how many plain tread tires are in use in many cities. In Sao Paulo, Brazil, you very rarely see a rubber non-skid. The taxi drivers all use plain treads and drive in the rain without chains. It is surprising how they get along and the speeds at which they travel. Already our tire people are putting on compaigns for their rubber treads.

and it is certain that good headway will be made. Undoubtedly when the European tire makers come back into the field they will have to come with rubber treads as well as steel treads.

U. S. A. tires generally got into the South American market in cart-before-horse fashion. We got in bad instead of good. We got a terrible reputation for rim cutting, for having cheap tires and tires that did not stand up. Fortunately we are getting over it, but not entirely.

Our Bead Trouble

Here is how it happened: Several of our tire builders, realizing that metric sizes were needed for South America, built metrics with beads to fit the standard English rim. When they got on the South American market they found the Michelin rim dominating the field. The Michelin rim differs from the standard English rim in that its hook to contain the bead is deeper radially. When our tires were put on these rims the bead did not fill the hook and the pressure came on the side of the tire, where it contacted with the edge of the rim. Rim cutting followed.

It was some time before explanations reached our factories and the correct tires reached South America. Then, too, some of our metric sizes were too small in tube diameter, really undersize tires. That got us in bad. Now, fortunately, one or two of our concerns are marketing metric sizes in South America that are of larger capacity than the European makes.

South America wants good tires. The car owners will pay for them, but they must have the mileage. It is not a question of our supplying the cheapest tire as much as it is supplying the best tire. We cannot afford to send anything but the best. One U. S. A. citizen who has lived in Buenos Aires for several years told of the errors of some of our undersized goods and of how escential it is to give good goods, particularly if we hope to hold the business. He further impressed on me the necessity of as low prices as possible. It is better for us if we are not ready with the right tire not to enter the field until we are. One of our large concerns followed this policy. It refused to sell in Argentina or Brazil until it had the correct bead and also the correct tire section. As a result, within the last few months it has been meeting with remarkable sales.

In one or two South American cities—namely, Sao Paulo and Montevideo—certain tire troubles may develop because of underinflation. This applies also to Santos, Brazil, where pavements are below the average. Rim-cutting complaints may come from these cities due to no fault of the tire. This underinflation regime will have to be counteracted. The United States Tire Co. in June started circulating in Portuguese a little tire booklet in Rio, Santos, Sao Paulo and other Brazilian cities showing the evils of underinflation. Good results were bound to follow and other concerns may have to actively take up this work.

(To be continued)

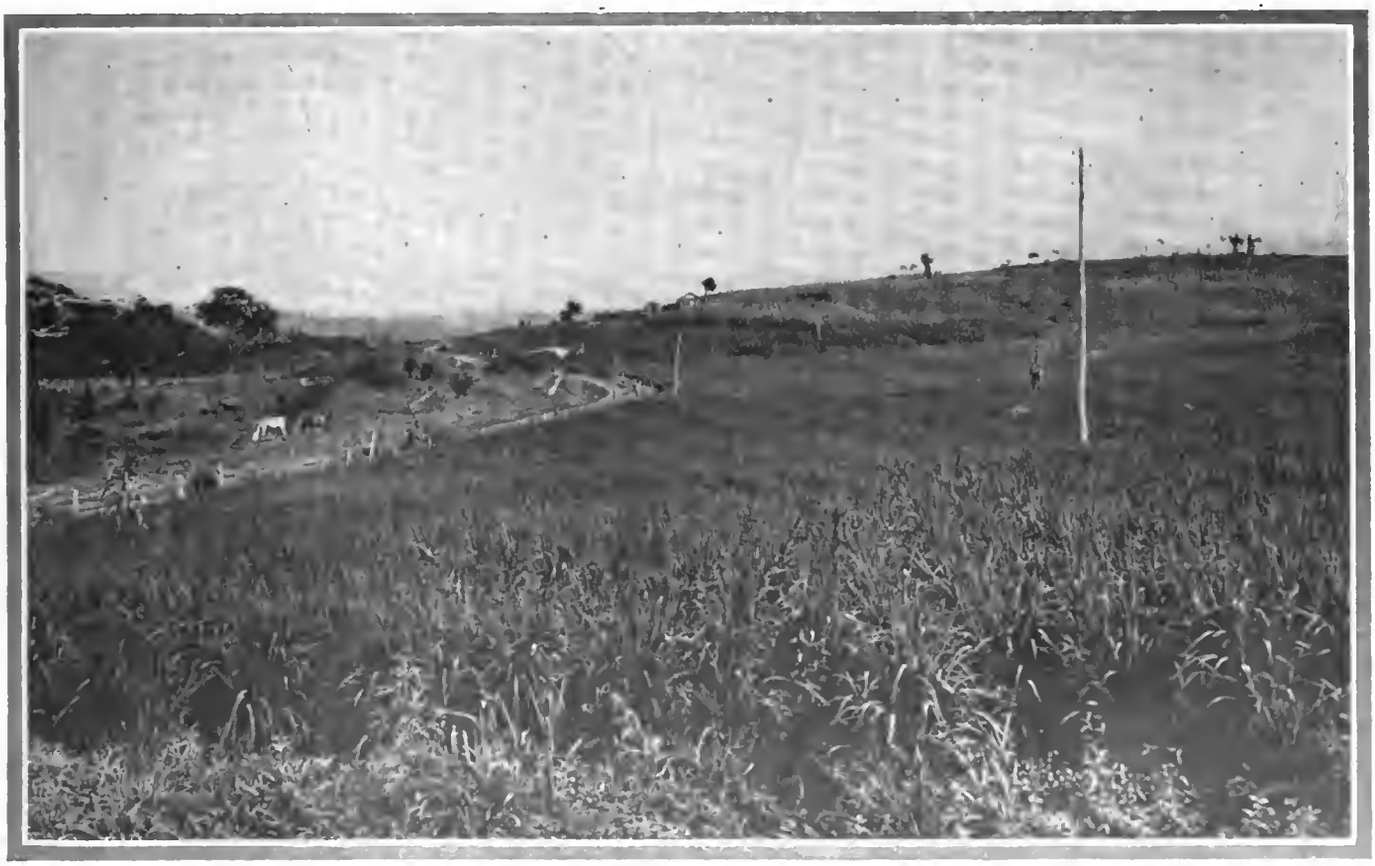
—

Venezuela Wants U. S. A. Cars

WASHINGTON, D. C., Sept. 2—The government of Venezuela, recognizing the supreme need for modern transportation facilities in that country, is active in encouraging the importation of motor cars and to that end has put them in the lowest or first customs class, the duty amounting to 68 cents per 100 lb. gross weight.

Gasoline is in the same customs class, but the expense attending the importation of the latter is such as to make the retail cost extremely high. The result is to limit the use of motor trucks, although it seems to have had little effect on the use of passenger cars.

Homer Brett, United States consul at La Guaira, is of the



General view of one of the great sugar cane sections of the State of Sao Paulo, Brazil. Although the coffee-raising industry of this State takes precedence among its commercial activities, Sao Paulo being the greatest coffee-growing region in the world, its large area, greater, in fact, than all New England, allows ample space for the cultivation of sugar-cane, etc.

view that there is a good future for automobiles in Venezuela. He says there are few countries where the modern motor car is so badly needed, due to the numerous towns and villages which have never heretofore been accessible except on muleback and which, because of the character of the country, never will be reached by railways. These isolated places, however, are the most healthful and the most prosperous in Venezuela, owing to their elevation and to the coffee crops produced near them.

The Venezuelan government, realizing the need for putting these out-of-the-way places in touch with the ports, is building wagon roads to all of these places. The result is that motor cars are penetrating to points heretofore not to be reached except by muleback, and they are making trips in two days which formerly required 2 weeks. In Ciudad Bolivar, on the Orinoco, there are numerous motor cars of North American make, and reports received from far beyond that point are to the effect every few days a motor car has reached some inland point in record time for that country as compared with the time made on muleback.

Reports received at La Guaira are that the invasion of Colombia by the North American-made machine has begun, and that it is being received with enthusiasm. Every steamer from New York these days carries a number of automobiles to different South American ports and the sales are steadily increasing each month.

The outlook in Peru just at present for the American-made car is only fair, but, as in other countries to the south, time is expected to work such changes as to open up a market worth cultivating. Cars of European make gained a foothold in Lima before the European war began, but the number in use there to-day is comparatively small. The streets of Lima are narrow and not well paved. Outside of Lima, the Peruvian roads are such that the successful use of motor cars upon them, until material improvements are made, is out of the question.

Electric cars are comparatively unknown in Lima. There probably are two or three such in use there. Later on, with electric power to be easily obtained in Lima, and at reasonable rates, the makers of electric machines might be able to build up a market there. Of the 300 or 400 cars in Lima, most of them are in the taxicab service, and of American make. It is the privately-owned car seen in Lima which is as a rule of European make.

Laminated Wood New Wheel Construction

Disk Design Is Strong and Light—Attractive in Appearance

THE latest idea in wheel building is to use laminated wood, the wheel appearing as a solid disk like a pressed steel wheel. This design has been produced by F. S. Merrill, Amesbury, Mass., Mr. Merrill being head of a firm that has been fifty-five years in the wheel building business. The principal claims for the new wheel are immense strength, moderate weight and handsome appearance.

Triangular Sections Combined

The wheel is built up in a very ingenious manner. Wood is cut into triangular pieces so that a number of triangles put together make up a circular sheet of wood. Several such circles are laid on top of one another, but the centers or places where the peaks of the triangles meet are not on a single center line. Suppose there are six layers of wood, then the center points of the six triangle assemblies will be spaced equally apart. Actually the points are arranged around a small circle, so that, if a nail was driven through each center the six nails would be six points on a circle. This is shown in diagram form in Fig. 1. Of course, when there are many layers the center points run in series. In the illustration the center points of the top series and of the bottom series are on the same line, but all the intermediate ones are staggered. The layers of wood are consolidated by heavy pressure. The inventor points out that this wheel, of which the strength is obvious, lends itself admirably to decorative painting. In natural wood it looks well, having none of that heavy appearance which often characterises a disk wheel of steel. The designs shown in Fig. 2 are suggestions for treatment in different colors and it is obvious that all sorts of patterns could be devised.

To Produce in Quantity

The wheels are at present obtainable by individual order at a cost of $175 per set of four, painted and finished in any style. It is expected that the factory will be open to consider the production of large quantities within a few months and the price would not be high when the necessary equipment is installed.

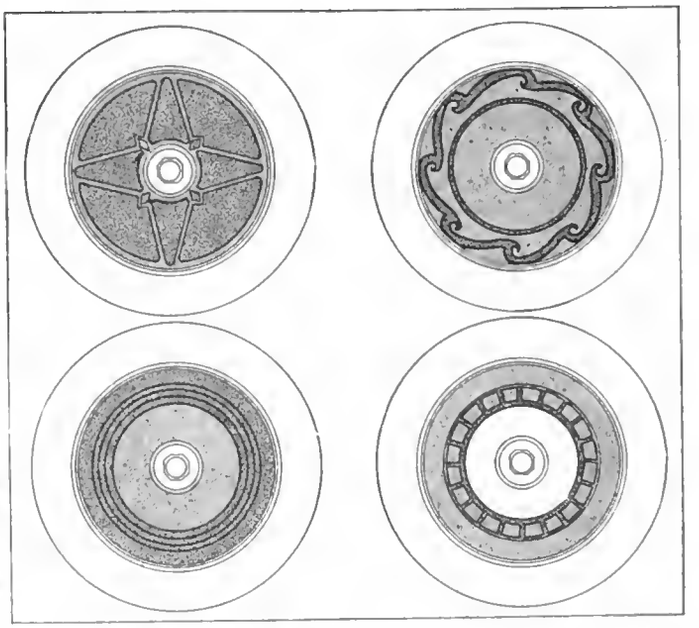


Fig. 2—Suggested schemes for painting laminated wood wheels in distinctive patterns

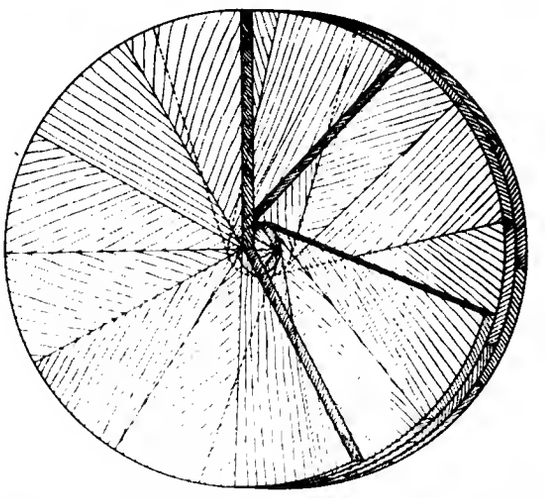

Fig. 1—Showing the construction of the laminated wood wheel in which each assembly of triangular pieces of wood has its center offset with respect to that of the next

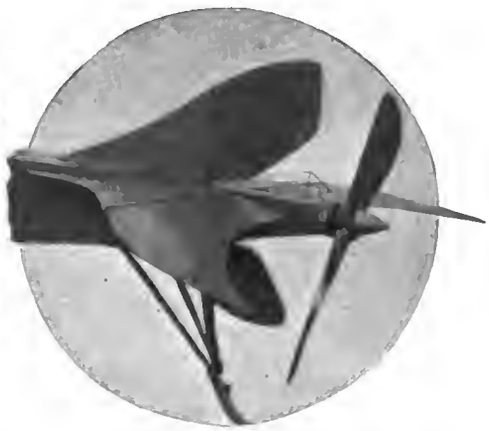
Effect of the War on Aeroplane Engine Design

By Granville Pollock

Three-quarter front view of the Ruby monoplane, and, below, peculiar construction of the tail, showing propeller mounting



¶ EDITOR'S NOTE: *For over a year Granville Pollock, of Buffalo, N. Y., was connected with an anti-aircraft corps on the western front in the present war. He had direct charge of the Pierce-Arrow trucks used to carry anti-aircraft guns, as well as other trucks needed for various uses in the corps. Mr. Pollock lived in an atmosphere surcharged with aviation matters and had a good opportunity to observe the practical working out of different types of aeroplanes.*

AFTER having observed that several automobile companies in this country have undertaken the construction of aeroplane engines, and others possibly considering the same, the writer is of the opinion that a word or two on what he has seen of this subject would not be amiss, and would possibly clear up one or two errors that seem to exist in regard to the actual motor situation abroad.

Before going further, the writer wishes to make clear the fact that this is not intended as a criticism on any work or previous discussion of this subject, but is merely offered as the result of 22 months' residence in England and Europe, fully half of the time having been spent on the actual front and always at least indirectly connected with aeronautics.

Under these circumstances, he could not help noticing the various machines, engines and the uses to which they were put, but also the service they were actually giving and the preference of one type of engine over the other for certain classes of work, all this under the most trying and exacting conditions, i. e., military service.

Engine housing and machine gun of a captured Fokker monoplane. The engine is a rotary Oberursel

No Revolutionary Tendencies

Contrary to the general belief, there has been nothing revolutionary in development, and while this may have seemed the case to the casual observer, engine limitations had long been known and acted upon by the best plane designers in France and England, and while a preference had been given to rotary and air-cooled engines, it was but the natural outcome of working with what one had, and not a preference for this type on the whole.

The development of the stationary water-cooled engine in these countries had been extremely slow, partly the fault of the individual engine manufacturer, but principally due to the lack of official and popular support. A similar state of affairs is practically existing in this country to-day or at least has been until quite recently, and it is but to be expected that without sufficient incentive to the contrary, manufacturers will always work along the line of least resistance and most profits. Further, the production of a really successful and efficient aeroplane engine is anything but an easy matter, and to that end might be cited the fact that one of the foremost designers of Italy, who has been continually engaged on experimental work along this line for the past 2 or 3 years, has not as yet produced an article that he would care to put on the market under his name.

Three Power Groups

And to add to the mechanical difficulties of the work, there are also the elements of cost and the interference with usual production, two items of no mean importance, which can be readily appreciated by those concerns who have undertaken this class of work; as well as the possibility of not finding a ready market for the product when it is completed.

But to return to the subject, the engine question has gen-

A fleet of Pierce armored trucks with anti-aircraft machine guns. Note the heavy dual rear tires and nonskid chains; also shovels and other tool equipment

erally divided itself into three groups, the first being that of machines requiring power up to 100-hp.; the second from 100 to 200-hp., and the third from 200-hp. up. The first and second groups are by far the more numerous in point of numbers, and while a great deal of experimental work is being carried on with a view of utilizing more power, as yet very little of it has passed beyond this stage, although the writer has seen and examined planes with four and five different units mounted, totalling up to and in excess of 500-hp. However, as stated before, these have not passed the experimental stage sufficiently to make their appearance in the field of conflict.

Aerophane designers who have produced a machine that belongs to the first group have almost entirely relied for power upon the air-cooled motor, the rotary dividing honors with the stationary. The best example of this is the Renault, this being the standard recommended by the Royal Aircraft Factory for its B.E. type, of which hundreds have been built, and these are giving satisfaction within their limits of operation. There is also the Farman, which uses the same engine as a pusher.

Three Leading Rotary Types

Of the rotary type, the three well-known makes, Gnome, La Rhone and Clerget, have all been used to advantage, although where large power of, say, 100-hp. is required, the Gnome has had the preference in the mono-soupape, which, in proper hands, gives excellent results.

All these engines have their faults and have been severely criticized, and the loss of several good French pilots has been attributed to their failure to stand up under hard usage; but this has almost invariably been the result of working these engines beyond their limits, either in length of flights, or in overloads for too long a time, such as a fast scout plane might be subjected to in a battle with several adversaries where frequent loss of altitude was followed by periods of hard climbing, conditions that quickly tend to heat an air-cooled engine, and especially one that is partially inclosed for streamline purposes. These cases were frequently met with when a number of crack pilots were operating on the same front, and rivalry was carried to the limit, and it was only to be expected that if an engine had any weaknesses at all, they would be brought out under these conditions.

The natural question is to ask why these engines were not replaced by water-cooled ones that would not overheat and sieze, or lose power when worked to their limits of endurance, but to those conversant with the weaknesses of this type of engine for this use, viz.—fast scout planes, an answer is unnecessary. One has but to visit Les Invalides in Paris, where some of the trophies of the war are on view, to see one or more types of German planes mounting a Mercedes engine of this type, that have been brought down as the result of a single shot through the radiator, and they will see this clearly enough, although it is but one side of the question.

A fact remembered by few people is that a rotary engine when in proper condition will give its full power almost from the first revolution and that no preliminary warming up is necessary even in the coldest weather, and this in itself is invaluable where a quick get-away is required, or where hangars are not available and weather conditions are adverse.

The Center of Support

Another fact, and one that is of moment where a designer has to produce the limit in flying efficiency, is that the center of support of the engine is always the center of power and thrust, and often is the common center of head resistance, and not infrequently this line intersects the center of gravity of the whole machine. The true significance of this fact is more readily appreciated by the constructor than by the engine manufacturer, and not infrequently is the cause of mystification on the part of observers where this type of engine has defeated a stationary of similar or slightly greater power on a duplicate plane.

The rotating effect of the engine also is a factor in reducing the effect of power impulses on propeller vibration, and in inducing a certain steadiness of flight which is much appreciated by experienced pilots; and this, with the fact of always being able to switch the power off and on, more than compensates for the lack of throttling range as compared with that possible in the stationary type.

As proof of these features, one has but to recall the recent exploits of the German Fokker machines, which use exclusively the rotary engine. Had it been possible to get the same results with the standard water-cooled engine as used in all other types of German planes, it is most probable that it would have been done, for they are certainly easier and cheaper to manufacture, and more efficient as regards fuel consumption, but the fact that they were not so utilized is significant.

So much for the virtues of the rotary when used with reasonable care and within its limits. While the life of this type is entirely dependent on the attention given by the mechanics at the base, they will last just as long as any other engine, and while slightly more expensive in the cost of replacements, it is not uncommon to see 3 and even 4-year-old engines still in service, while many are still at the front that flew over the Channel at the commencement of

Side view of Pierce anti-aircraft armored car with the crew. This also shows the machine gun mounting

the war. Proof of their long life is to be seen in any of the school machines in England and in France; and at Hendon, especially, more pilots have been trained behind old "50" and "80" Gnomes than in all the rest of England combined.

Rotaries for Scout Work

That this type of engine will always be popular for the fast scout and dispatch class of work, where flights are for comparatively short duration, is the opinion of some of the best constructors in Europe; but that for any other uses where fuel efficiency is to be considered, then, of course, the other engine is unquestionably the best, as might reasonably be expected.

This, however, brings us to the second group of machines, viz.—those that are primarily intended for bomb dropping, lengthy periods of observance for artillery fire, raids and armed reconnaissance work, where loads are carried with power requirements up to 200 to 250 hp. Of engines for this class of work, there are many well suited to their work, comprising both radial, vertical and V types, although the six-cylinder vertical is by far the most popular and the most efficient for single installations; or where one single large power unit is not practical, two smaller ones are usually mounted out on the wings.

Caudron twin engine biplane on exhibition in Paris after being riddled with shot in active service

Austro-Daimler of High Power

Under these conditions, it has not only proved more efficient as regards actual power output, but is far easier to streamline and consequently diminishes head resistance, an item not to be overlooked on a large machine. Of this type, the best known is the Mercedes, although it is not by any means the best, as under comparative tests, the six-cylinder Austro-Daimler has shown a much higher efficiency, giving a power outpt that on occasions has risen to 147 hp., at 1400 r.p.m., a very high figure indeed when it is remembered that the propeller is not geared up, and working perfectly with only 3½ gal. of water!

In a case of this kind, it will be readily seen that two of these engines will give a higher efficiency than a single installation of, say, 250 hp., while propellers are regularly turned out by a prominent French concern that has no trouble in holding their efficiency at this speed and even higher.

This type of engine has been generally confined to the well-known two-seater tractor class of work, to which it is well adapted, as in this case it is usual to mount the engine with the heads exposed to get the benefit of the propeller draught, and also facilitate inspection or adjustment.

For this type of work there is no particular limits as to width of the mounting, and an eight is just as practical, although at high speeds the difference in vibration is not noticeable, as the success of the Renault eight has proven. It is, therefore, quite clear that there is nothing to be gained in increasing the number of cylinders or parts, as the efficiency does not keep pace with the complications for engines of this power.

Fuselage Design Problems

Fuselage design always has been a point of difference in opinion among the various designers, the smallest as to width or depth having always been Deperdussin, while such firms as Hanriot and Nieuport have always been noted for their deep-chested and broad construction, both types giving equal satisfaction in the hands of their respective pilots. It would, therefore, seem to be a matter of personal opinion and the class of work for which the plane was in intended, as machines with fuselages of one and even one and a half meters width have been seen by the writer to give excellent results, while the question of streamline or head resistance presents no difficulties, as a perusal of Eiffel's work on this subject will readily show.

On the other hand, when a machine of a size is built that requires over 250 hp., the purpose for which the plane is intended is generally such as to preclude the use of the forward part of the fuselage as an engine bed, and up to the present the tendency has been to mount them out on the wings so as to get the benefit of this large space for other uses, often mounting guns on the rails, which gives an extremely wide radius of action as well as permitting the wireless operator to work in peace away from the noise and the influence of the engines.

That this item is worth considering has been proven by the fact that the sending radius for wireless on planes has been extended to 200 miles by actual and frequent tests, which the writer does not hesitate to vouch for.

Mounting on the Wings

So far as the mounting of engines on the wings is concerned, the best results seem to be with not more than two different units, for while more have been tried and may eventually be used, the difficulty has been to mount them in such a way as to keep the slip-stream of one propeller away from the others, and not get the weights so far out on the wings as to make the whole machine cumbersome and heavy, to which is added the almost impossible task of keeping the engine speeds uniform.

With this in mind, the construction of really large power plants is now the most important of aeroplane engine work now going on in Europe, and units of 300, 350 and even greater are to be expected along shortly and undoubtedly these will be of the 12-cylinder V type, with a fairly wide range of throttle control, and a high fuel efficiency, though in this case the question of gross weight will not be the item it has been in the past, for in all probability the difference of a few kilos on an engine of this size will make very little difference to the size of the machine it is intended to propel. At all events it will be more up to the designer of the plane

Automobile Practice in Tractor Design

Many Valuable Pointers in Detail, Though General Features Differ Widely—Truck Construction Also a Possible Influence—Ultimate Tractor Engine of Automobile Type

By A. Ludlow Clayden

IN a previous article it was stated that the tractor to-day is what the automobile was in 1903, in so far as its detail development is concerned. The reason behind tbis is simply that the average tractor seems to be about as far away from the ideal as did the automobile 13 years ago. Examining a collection of tractors shows instantly that the new industry bas much to learn from automobile experience in the way of obtaining reliability and durability. It probably has much to learn in detail design, but little if anything in general feature. Tbat is to say, tbe tractor needs to be vastly different from the motor truck in general by reason of tbe totally different requirements, but it can advantageously be far more like the truck in petty detail; the sort of detail that gives trouble and annoyance of a petty character.

For example, it is only in a very few instances that accessibility has been given any consideration whatever in tractor design. Control rods and bell crank connections are wrapped around each other and mixed up till it becomes quite a task to follow the linkage, carbureters are buried deep in a mass of moving parts, magnetos without covers and of non-waterproof type are employed, clutches which have less work to do than a motor truck clutch are made with expanding segments and a conglomeration of levers and cams that make adjustment vastly difficult; instead of grease cups there are exposed oil holes to collect grit and waste lubricant. It would be possible to continue the list indefinitely, but enough has been said to indicate the sort of way in which automobile experience can be brought helpfully to bear on tractor design.

Tbe automobile was first built up, feature being added to feature as the need became apparent. Then followed a period of unification and simplification. It is this last that the tractor needs more than anything else to make it a finished macbine instead of a half-finished one.

Develop Machine First

This criticism of things as they are is not intended to be destructive. It is necessary to develop a machine first and simplify it afterwards. At present the tractor has reached a stage wbere it is ready for the simplification process to begin, and in isolated instances it already is beginning. Let it not be forgotten that the more like an automobile in its detail the tractor becomes tbe easier will the farmer be able to care for it. The American farmer knows his automobile, knows how to use it and how to look after it. Therefore, whenever a *detail* of automobile practice can be turned to account it is wise to employ it.

Major Problems of Design

Sounding the otber note, it must also be remembered that automobile experience is practically of very little use in settling tbe *major* points of design. For the power plant the requirements of the motor boat or even the aeroplane come much closer to the tractor requirements tban do those for any sort of road vehicle; the tractor calls for full power all the time, full power for hours or even days on end. This means that in the engine a larger factor of safety is necessary throughout. We cannot safely use tbe same unit pressures that are correct for a motor truck, and we cannot, of course, look for the skilled attention that enables the aviation engine to keep its capacity for long runs. Likewise the boat motor does not supply an exact parallel, for there is little need to limit the weight or size of the water-borne engine.

Tbere is a school of tractor engineering which believes that none of these examples is anywhere near the proper tractor type, and this is the school which has taken the stationary gas engine as a basis for developing the tractor engine. The automobile engineer is instinctively prejudiced against very large cylinders and heavy, slow-moving parts, so an automobile engineer's criticism may be discounted a little, but is it not true that the prejudice against the stationary engine type is well founded?

Modern Engine Tendencies

Go back a little way in automobile history and we see the gas engine type strongly supported, we see Olds, Reo, Cadillac and many others pinning their faith to a huge single or twin cylinder; earlier yet, and Benz, Daimler and many others are found.

Now wbat was it that experience taught? It taugbt that the massive engine "built on conservative and well-tried lines" was *not* the most reliable or most satisfactory type. It was the superior qualities of the vertical multi-cylinder engine wbich caused the abandonment of tbe large cylinder idea for automobiles. Even in the stationary engine field there is a strong tendency toward more cylinders of smaller size. The most modern engines of tbe leading German Diesel makers have had many vertical cylinders, because they gave less trouble; in England the high speed gas engine has been developed in recent years and has taken mucb from automobile practice. The automobile engine, the engine of the motor truck, the tractor or the aeroplane, is working under far more strenuous conditions than any stationary engine. It was this fact that has led to the elimination of the old type for use on vehicles; it simply was not up to the demands of the service. Tbus it is perfectly reasonable to assume that the old type will be still less able to cope with the heavy demands of tractor service than it was with the demands of the passenger car and truck to which it proved unequal.

No doubt this view will be strongly combated in many places, but it is a view that is shared by many in the tractor business, where the impression is strong that those wbo are fighting against the so-called automobile type of tractor engine are digging a pit for themselves and will soon find it necessary to climb out and start afresh.

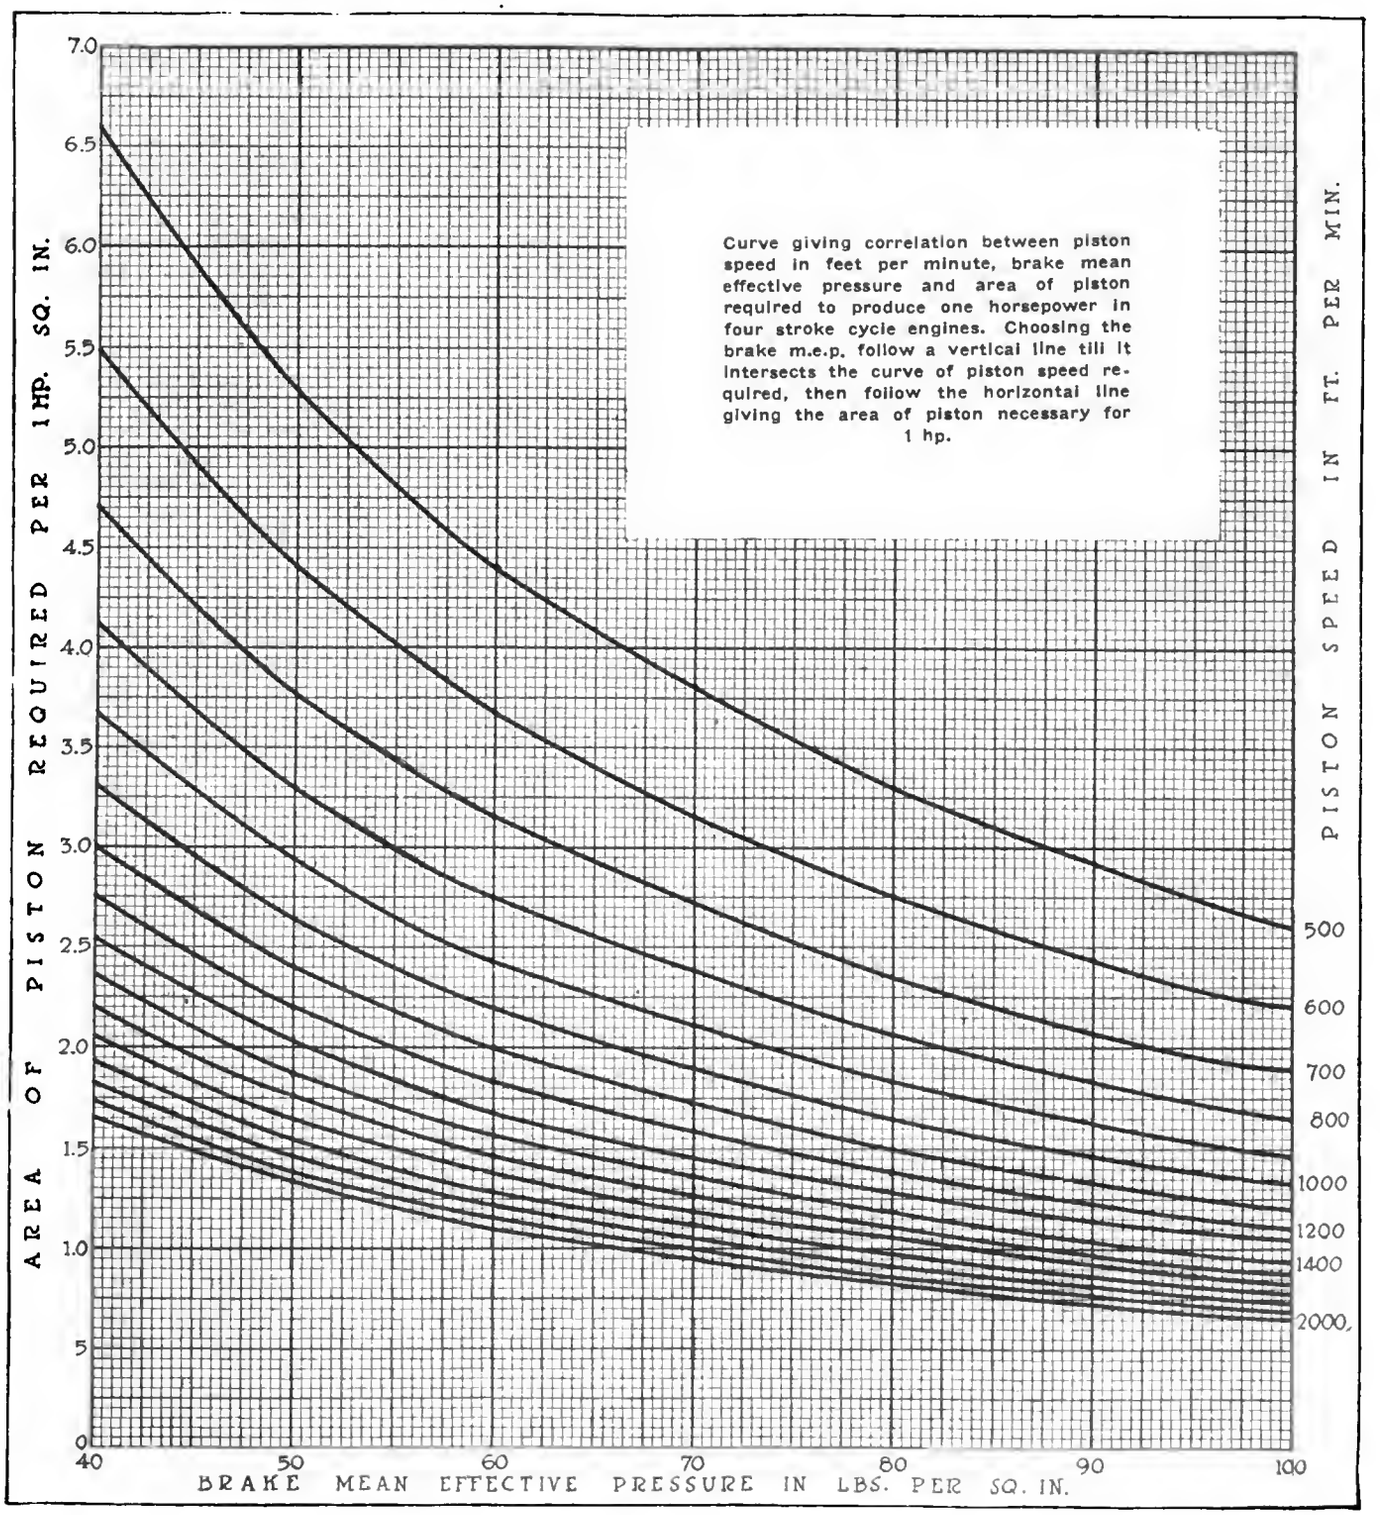
Determining Engine Size Necessary

To settle the proper size of engine for a tractor is very difficult. It is a matter of experience, and experience is not too plentiful. There is one way and only one way to figure it successfully and that is to start at tbe drawbar, taking tbe pull required and the speed of pulling as tbe fundamentals.

Then comes the efficiency of the machine and last the engine power necessary to give the required pull via the transmission. Having settled this there come the matters of piston speed and the best mean effective pressure, to be considered.

Now, there is no close agreement as to the proper drawbar pull or horsepower. It may be reckoned conveniently on the basis of plows to pull. For one plow the average pull required is not a safe basis for calculation unless that average is taken from a vast number of experiments. It varies greatly with the sort of soil and the condition of the soil and, of course, the depth of plowing. Now, there is not yet agreement as to the tractive effort that should be provided per plow, nor as to the best speed for plowing. A pull of 1000 lb. is apparently enough to take a plow through anything, and half or less than half this is sufficient under easy conditions. As to speed, 2 to 2½ m.p.h. is the rule, but the machines that exceed this speed certainly appear to have a more pulverizing action upon the soil. However, if we assume 2½ m.p.h. as the best speed, and take a mean value of 700 lb. as the tractive effort that should be available per plow at this speed, the results of calculations on these premises will not be far from the truth. Reducing the speed and traction to horsepower units, this means that the drawbar horsepower per plow allowed in the design should not be less than 4.7 or, say, 5 hp.

Now comes the efficiency of the transmission and the ma-



chine as a vehicle; gearing efficiency and power taken to propel the machine. Naturally this can vary greatly, hut several of the most prominent manufacturers are content to take the drawbar horsepower as equaling half the brake horsepower at the flywheel. Some estimate less than half and others a trifle more. Taking the exact 50 per cent as the loss between flywheel and drawbar this gives us as a necessary allowance 10 b.h.p. of engine per plow.

Supposing this serves as a hasic point from which to start the engine design we have next to decide the best piston speed and brake mean effective pressure. For motor truck engines the old formula $Hp = \frac{N\ D^2}{2.5}$ still holds fairly true. The formula assumes a piston speed of 1000 ft. per min. and a hrake mean effective pressure of approximately 67 lb. per sq. in. If we raise either speed or pressure the weight can be reduced and the cost can he cut, but there are corresponding drawbacks. Increased speed means still greater gear reduction and lower gear efficiency; increased pressure means more liability to ignition trouhle and more rapid carbonization. The reverse is, of course, true if speed or pressure be lowered, hut weight and cost increase.

Some Weight an Essential

Ohviously it is possible to guess at it and hope to strike the best mean, hut there are still some other factors that can he considered. First we must have a certain amount of weight, so there is no object in trimming the engine weight to the last ounce. Second, the higher the pressure the more "delicate" does the engine become, the more susceptihle is the power to small imperfections in the valves, ignition or carhuretion. Third, if the pressure or speed are above a certain amount pressure lubrication is essential.

These are three reasons against high pressures or high speed, now let us turn to the other side of the picture. Here we see that first, decreasing the pressure decreases the efficiency of combustion; a fairly high compression and consequent fairly high mean pressure give better fuel efficiency. Second, large slow speed engines may have smaller unit pressures, but must have larger total pressures which means that the force of each explosion becomes more of a hammer blow and so causes more shock to the engine parts and the transmission. Third, the large engine occupies a greater amount of space and when it is necessary to overhaul it, or scrape out carbon, which must be done periodically, the operation is a far more serious undertaking.

Altogether it is hardly surprising that tractor engineers have found it impossible to agree completely as to exactly where the happy mean lies.

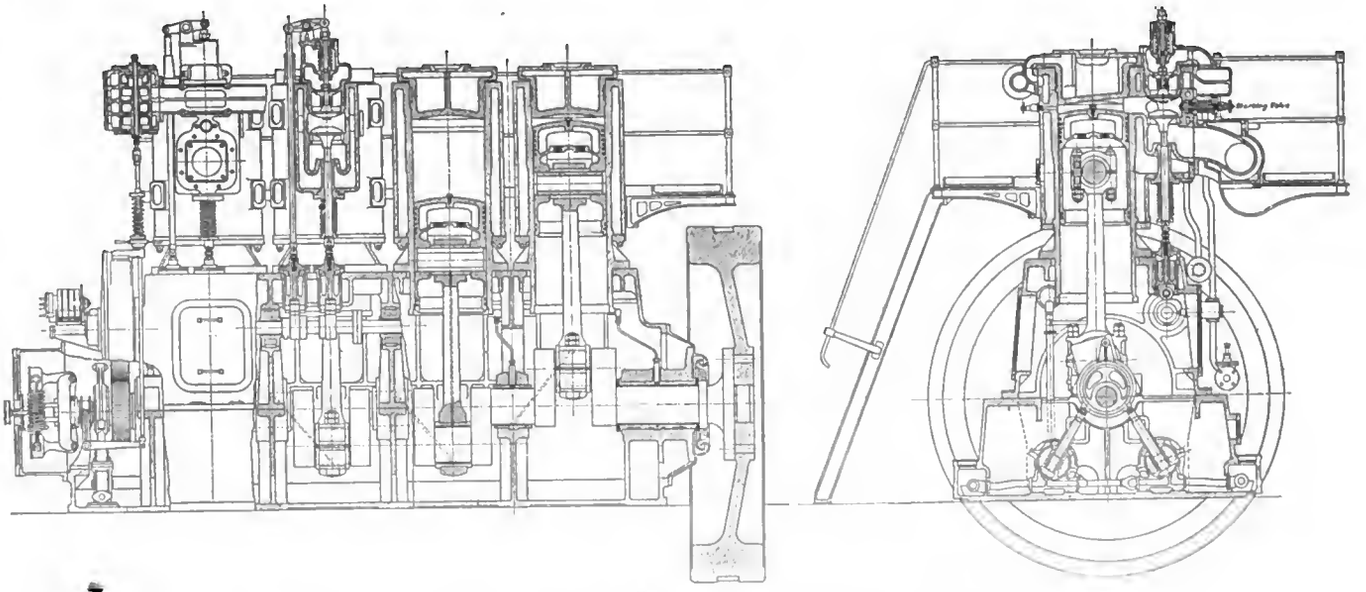
There is one thing that can be stated positively, however. It is based on motor vehicle experience admittedly, but that does not weaken the argument, and this is that engines with less than four cylinders ought not to be considered. Even if the stationary gas engine type of power plant is chosen it ought to have four cylinders as the low limit. This is because the vibration from any lesser number is destructive. With a stationary engine, on a massive bed set deep in concrete, vihration can be combated, and in driving by belt vibration in the engine is not transmitted to the machine driven, but on a vehicle engine vibration *must* pass through every portion of the machine before it can finally be ahsorbed hy the ground. It is possihle to ohserve tractors to-day in which the radiator top swings an inch from side to side with each explosion.

Further, as regards the punch applied to the gears in the transmission by large individual explosions, this is greater than might at first be imagined, greater than it would he on any other type of vehicle, because the tractor is positively driven hy the explosions. A tractor has not an eighth of an inch of "coast"; throw off the switch and it stops dead with a bump. Practically it is impossible to supply enough flywheel to do more than carry the crank from one explosion to the next.

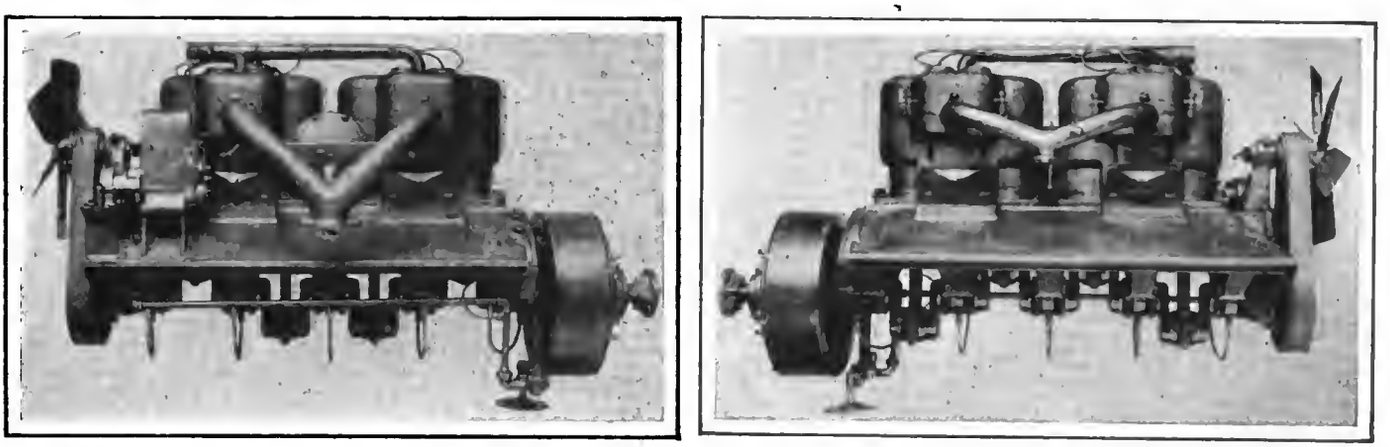
We have passed through the selfsame arguments and theories for and against the stationary type of gas engine with the development of motor trucks. Surely there is no need to go over all the ground once more with the tractor. It is often said that a son dislikes to profit from his father's experience, preferring to have a free hand to acquire his own, but life to-day is conducted at a speed which makes this hardly possible in the walks of industry.

Automobile Type the Ultimate

It is therefore safe to say that the automobile type of engine is going to be the ultimate type of tractors just as it has become the conventional type for trucks. If this be admitted, consideration of what a tractor engine ought to be can be narrowed down considerably. In brief it needs to be a large truck motor which will withstand usage a trifle rougher and more arduous than that given the average truck power plant. There are some truck engines which are perfectly suitahle for tractor work, hut others which are not, so



This is not a tractor engine but a new British gas engine of 900 hp. with 17 in. bore and 20 in. stroke. It shows in a striking way how automobile practice is being adopted for stationary engines of the larger sort



Engine of the J. I. Case Plow Co. tractor. This is a particularly rugged example of tractor motor based upon the automobile type

one might say that the very best of truck motors is what the average of tractor engines ought to be.

One thing cannot be stated too strongly, and this is the need for protection against dust, mud and water. The tractor engine operates under the worst possible conditions. Either the whole tractor is hidden in a fog of dust, or it is splashed with mud inches thick. It stands unprotected by covering, in rain and snow, it will be utterly neglected for a month and then called upon to do full work immediately. The tractor engine ought to be capable of being buried in slime at the bottom of a pond for a month and then dug up and put straight to work without any overhaul.

A side issue suggested by this consideration brings up a point where the tractor should not follow automobile practice. The engine should be under a hood, of course, but the radiator should *not* be the front end of the hood. The radiator should be separate, standing out somewhere in front so that it will be exposed to all the winds that blow, and the fan can be outside with the radiator. The engine should be boxed in so that the only communications it has with the outside are the carbureter air intake and the exhaust pipe. There might just as well be no hood at all as a hood with a fan to blow dust into it. This has always been an absurdity in passenger car and truck construction; it is far worse than absurd on a tractor.

As regards details, any engine that is running at full power 100 per cent of the time is placing a severe stress upon the valves and the ignition, particularly upon the spark plugs. Spark plug trouble is the main difficulty against which tractor engineers are contending at present, and it is intensified by the high temperatures produced by using kerosene as fuel. The answer seems to be to use the small plug now adopted for racing engines and likely to be standardized for aeroplane use. Several tractor engines are already fitted with the small plug and it is probable that more will follow.

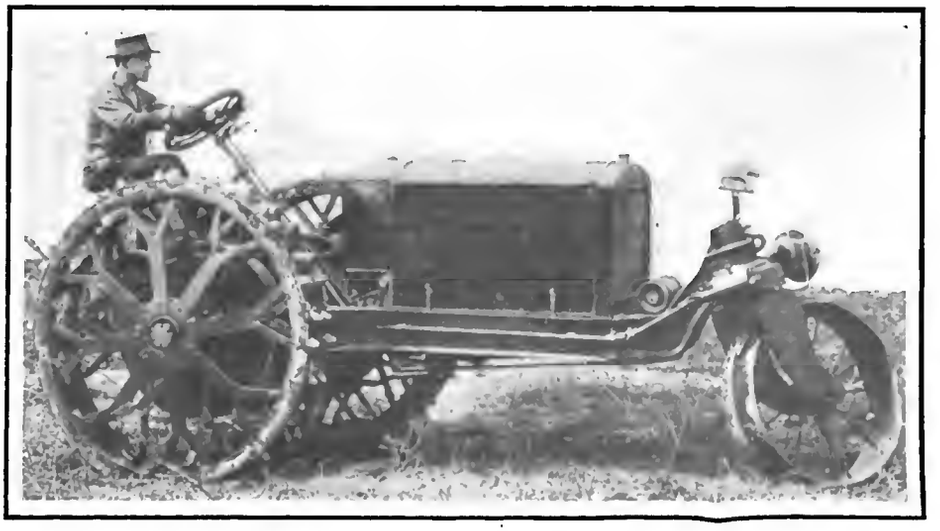
Valve areas have to be fairly large, though not very large in proportion to the cylinder size, since there is no need for high speed. Since valve trouble is always due directly or indirectly to valve temperature with an "all the time full power" engine, it is manifestly important to cool the valves as thoroughly as may be, and this suggests that it may be found advisable to use four valves per cylinder rather than two large ones. For the bigger sizes, where 60 hp. or more is wanted, a T-head cylinder with a pair of valves each side seems better engineering than any form of cylinder with two very big valves. This is just theory, it has not yet been tried out in practice, but it is worthy of note that Diesel engines, which have the severest temperature conditions of all to combat, most commonly employ multiple valves.

Since reliability, freedom from attention required and absence of parts affected by heat are three important requirements for a tractor engine there also seems some reason to think that the Knight motor would be eminently suitable. It has not been used much for trucks in America, but has been employed quite extensively in Europe and has proved extremely satisfactory for commercial vehicles. It possesses two outstanding advantages which are admitted freely by all poppet valve enthusiasts. One is there are no valves to grind or adjust, and the other advantage is that the Knight engine is far less affected by carbon deposit than any other type of gasoline engine. The writer has always been of the opinion that the admitted advantages of the Knight and other sleeve valve engines were far more important in the commercial field than in the passenger car. The chief drawback is cost, of course, but prime cost is not of prime importance when operating cost is large in proportion as it always must be.

Mastodon Tractor Ready

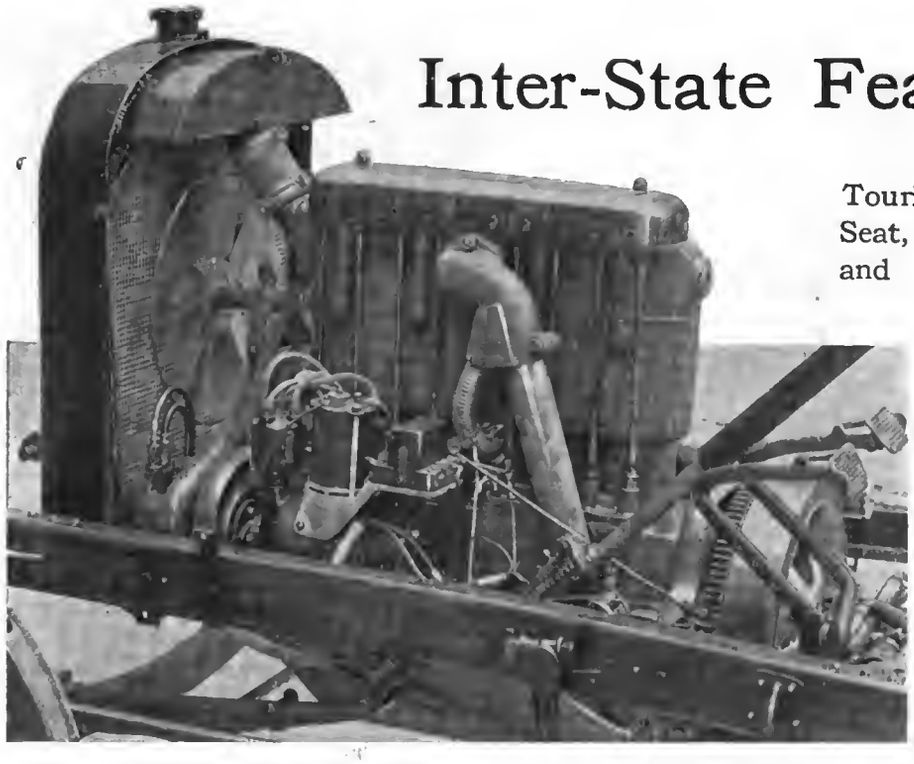
THE Mastodon tractor, made by W. E. Hosch of 2111 Olive Street, St. Louis, Mo., gets its name from the tractor wheel, which is patterned after the mastodon hoof, and it is claimed that it will travel readily over any soft or rough surface.

The machine is compactly built and every moving part is inclosed and runs in oil. Special attention is directed at the ease with which it is handled. Mr. Hosch expects to put the Mastodon tractor on the market this fall. He says that it is the result of 6 years' experimenting.



Inter-State Features Bodies

Touring Car with Divided Front Seat, Four-Passenger Roadster and De Luxe Delivery Car



Exhaust side of 3½ by 5-in. four-cylinder engine used in the 1917 Inter-State, showing mounting of lighting and ignition equipment. Overhead valves and the removable cylinder cover are features of this engine

NO mechanical changes have been made in the Inter-State for 1917, the only additions to the line being a divided front seat touring car and a four passenger roadster listed at $895. There is also a de luxe delivery car mounted on the same chassis, priced at $850.

Distinctive finish features the two new passenger bodies, the divided front seat touring car having for its standard colors a dark green body with cream wheels and the running gear finished in black. The four-passenger roadster is furnished in a gun metal gray body with battleship gray wheels and upholstered in brown Spanish leather. Both cars have the modern low, long lines and the Inter-State Motor Car Co., Muncie, Ind., has made a point of roominess and comfort in the seating arrangement.

In the five passenger divided seat job, the driver's seat can be moved backward or forward to suit the height of the driver, giving an arrangement which will be suitable for anyone to drive. As the adjustment is quickly and easily made, two people of different statures can drive the car with little inconvenience.

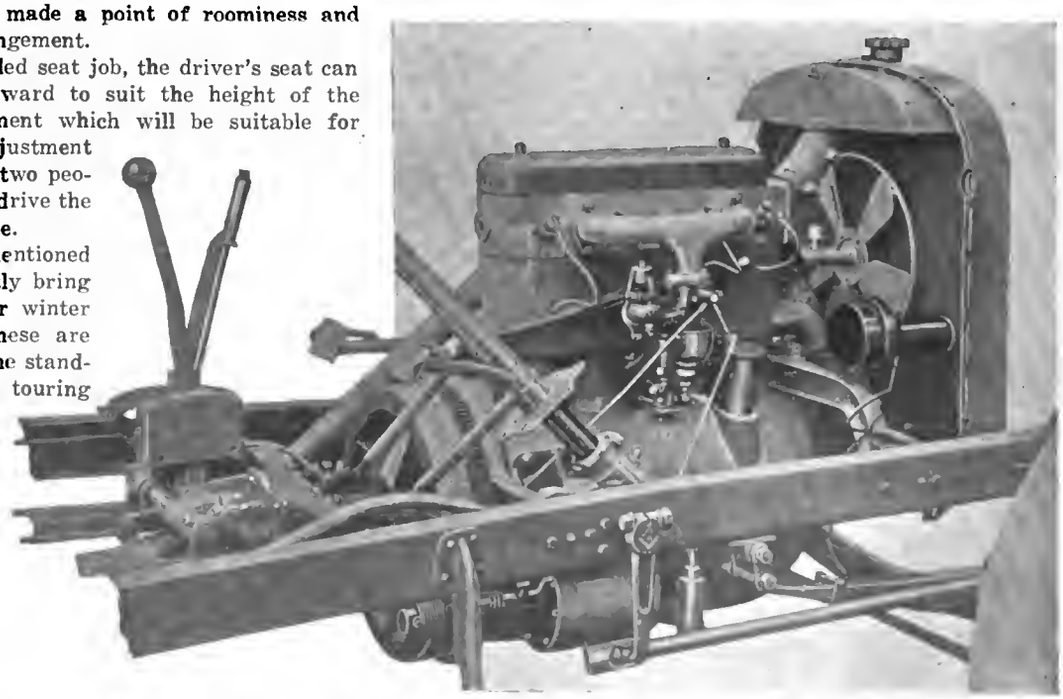
In addition to the cars mentioned the Muncie plant will shortly bring out some inclosed bodies for winter use, although details on these are not at present available. The standard series T five-passenger touring car, which is a conventional design with continuous front and rear seats, remains unchanged. It sells for $850, as does also the series TR roadster body, which is a continuation of the design of last season, except that a door has been added on top of the turtle back. This new feature permits of ready access to the large baggage compartment immediately behind the front seat and renders it possible for this space to be used without having to remove the tires. Both doors to this compartment can be securely locked and are thus rendered dust and waterproof.

Overhead-Valve Engine

The engine is a specially-built Rutenber job, having the four cylinders cast in a single block with the valves located overhead in a removable cylinder cover. The bore is 3½ in. and the stroke 5. Drop forged I-beam connecting-rods, having a length of 9¼ in. between bearing centers, are used. The rod bearings are 2 in. in length and 1¾ in. diameter. They are lined with babbitt, as are also the bearings for the 2-in. carbon steel drop-forged crankshaft. The dimensions of the main bearings are 2 in. in diameter and 2¾ in. in length for the front, 2 in. in diameter by 2 in. in length for the center and 2 in. by 3⅜ in. in length for the rear. The bearings are steel backed with the babbitt lining accurately scraped to a finish fit.

Lubrication is by circulating splash system operated through a gear-driven pump from the camshaft. The oil is contained in the bottom pan of the crankcase, being carried by the gear pump to the bearing leads from this reservoir.

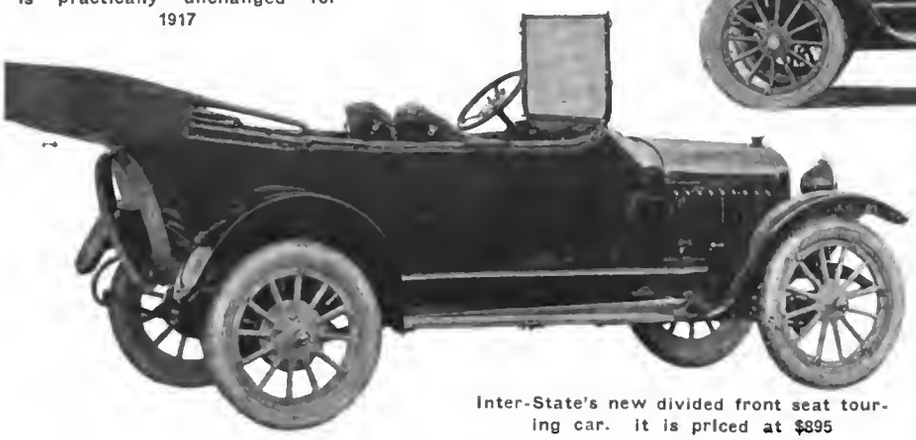
The gasoline system consists of a cowl tank and a Schebler



Intake side of the Inter-State engine, showing starting motor, horn and carbureter mounting

Above — Inter-State roadster, showing easy access to compartment under rear deck for tires, tools, etc. Mechanically the car is practically unchanged for 1917

Right—the new four-passenger cloverleaf roadster, showing the body contour and divided front seat



Inter-State's new divided front seat touring car. It is priced at $895

1-in. carbureter. The gasoline flow is by gravity, as sufficient hydraulic head is given by the cowl location of the tank, which is not only high, but is close to the carbureter and hence affected only to a minimum degree by variations in gradient. The gasoline gage which registers the depth of the fuel tank is mounted on the cowlboard in plain view of the operator.

Remy Electric System

Electrically the Inter-State car is Remy equipped, having this system for starting, lighting and ignition. The distributer is mounted on the left side of the motor block with the coil just behind. The ignition distributer drive is taken by bevel gears directly off the generator shaft which is connected by a flexible coupling to the same shaft which operates the oil pump. The starting motor is at the rear

New De Luxe delivery car on Inter-State chassis. It sells for $850

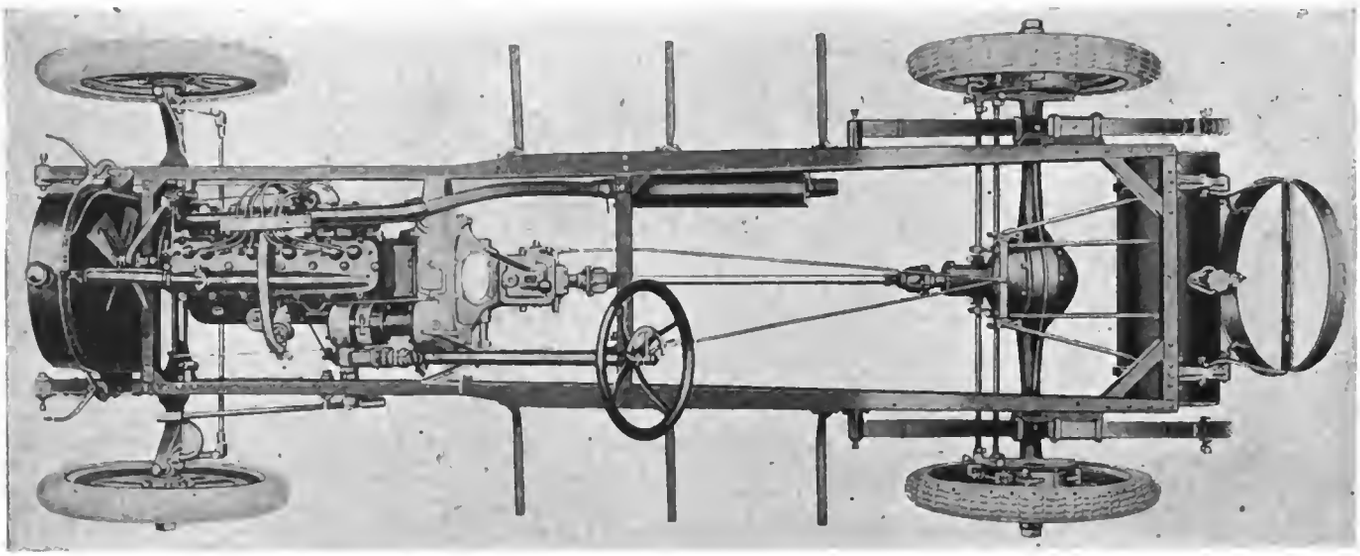
right and engages with the flywheel which is equipped with a ring gear on its forward face. The heavy wiring is inclosed in flexible metal conduits.

From the engine the drive is taken through a leather-faced cone clutch to a three-speed gearbox. There is a cross frame member just behind the clutch supporting the clutch shaft and the forward universal and torque yoke. The gearbox itself is mounted on the rear axle with the face of the box bolted directly against the rear axle housing. A direct ratio of 4 to 1 is secured through the bevel gear axle, which is supported on Hyatt roller bearings. The axle shafts are floating.

A pressed steel bottle-neck frame is used with the side channel members 3½ in. deep with a 5/32-in. section. The wheels are wood artillery type, having twelve spokes each 1⅜ in. in diameter. They are equipped with Firestone demountable rims carrying 33 by 4-in. tires and with non-skids fitted as standard equipment in the rear. Tires are Goodyear. Three-quarter elliptic rear springs are used, the length of these being 46 in. and the width 2 in. The front springs have a length of 36 in. and a width of 1¾ in.

Five Body Styles

With the additions mentioned there are at present five bodies mounted on this chassis. The standard five-passenger touring known as series T has undivided front and rear seats. The TR is the standard roadster with rear deck, having a two-passenger capacity. The TD is the divided front seat job with the adjustable driver's seat feature. Series TR four is the new four-passenger roadster and TC is the parcel delivery wagon of 800 lb. capacity. It is especially adapted for the use of florists, confectioners, clothiers and grocers. There are double doors in the rear and the loading dimensions give a width inside of the body at the top of 46 in. and at the bottom 42 in. The height is 51 in. and the length from the back of the seat to the doors is 65 in. In finishing these bodies all the fenders and dust skirts are black enameled and baked in the ovens of the Inter-State factory. Selected natural wood wheels will be furnished on any of these cars at $5 extra per set.



Paterson chassis for 1917 which is fitted with a Hess floating axle and uses the Hotchkiss type of drive

Two New Paterson Models for 1917

Four-Passenger Roadster and New Touring Design with Double Cowl—Floating Axle and Hotchkiss Drive

THE 1917 Paterson chassis, built by the W. A. Paterson Co., Flint, Mich., has a new rear system and will be fitted to a four-passenger roadster body in addition to a new design of touring car body with the popular double cowl effect. The offering of one of the so-called sociable types of roadster or close-coupled bodies is a new thing with Paterson, heretofore only the touring car body being offered. The price is $1,065 with the touring car body.

Mechanically, the only changes in the chassis, which is powered with a six-cylinder Continental engine, are the adoption of a Hess floating axle, and the use of the Hotchkiss type of drive, whereby the driveshaft back from the gearbox is open and fitted with two universal joints, and the drive and torque are taken through the rear springs, the main leaves of which are made strong enough to take on these added duties. Formerly an inclosed driveshaft with a single universal at the front end has been used, the newer construction being lighter and doubtlessly much more efficient as applied.

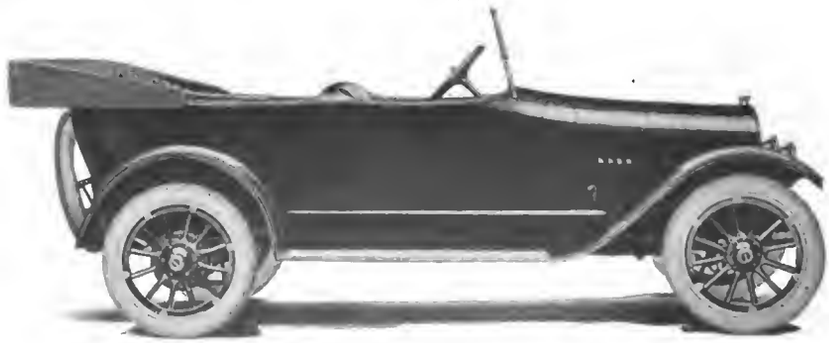
Bodies Are Larger

In the body, perhaps the most notable differences are the new lines and the wider and longer dimensions which add to the roominess of the vehicle. At the back of the front seat the double cowl idea has been meritoriously worked out in conformity with the general lines of the car, and the straightness of the lines has been accentuated by raising the radiator and hood 1½ to 2 in. As an added touch of modernity the windshield has been given a slight slant, the mistake of making the incline too great not being committed. To give more leg-room for the front seat passengers, the front seat has been moved back a few inches, and to further add to the car's comfort and good looks, the upholstery is of the type in which there are parallel plaits instead of the tufted form. Auxiliary seats to fit in the tonneau can be furnished if desired, thus giving ample room for seven should the purchaser wish to convert the car into a vehicle of larger capacity.

Standard Units Used

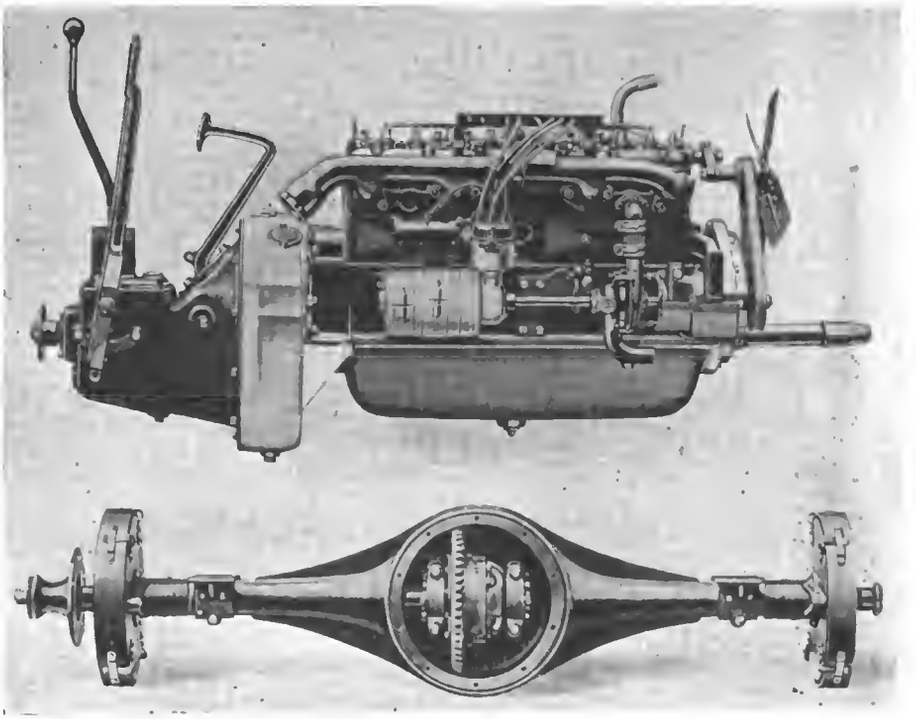
There is nothing of the radical about the Paterson car. It adheres to conventional design, utilizing standard units. A Warner gearset bolts directly to the motor to make a unit power plant, and a leather-faced cone clutch is also utilized, the action being so worked out that very little effort is necessary to press out the clutch pedal for gearshifting. The new axle is fully demountable, with a one-piece pressing, webbed outwardly, serving for the deffefential housing and the axle tubes as well. It is fitted with spiral-bevel driving gears, the advantage of which is now too well known to be needful of further discussion here. Springs are three-quarter elliptic in the rear, and attached to the rear member of the frame is a large gasoline tank that supplies its fuel to the carbureter through the Stewart vacuum feed system. Tires are 32 by 4 on demountable rims, with the rear pair provided with non-skid treads, and the wheelbase for either body model is 117 in.

Electrically, the car is Delco, employing separate starting and lighting units, with the ignition distributer mounted at the forward end of the generator. The new type of Stromberg carbureter is fitted.



New Paterson touring car with double cowl. It sells for $1,065

It is not necessary to go into a detailed description of the 3¼-in. by 4½-in. Continental engine. It might be said, however, that the cylinders and upper half of the crankshaft are cast in one piece, with the cylinder head detachable as a unit. Valves, exhaust manifold, water pump and electric unit are all on the right, which leaves the left side exceptionally clean. In fact, nothing is carried on this side with the exception of the carbureter, this bolting directly to the casting, well up in the center. Distribution of the incoming gases to the several intake ports is done within the casting itself, affording excellent heating of the incoming gases and eliminating the necessity for an elaborate jacket arrangement for the carbureter.



Six-cylinder Continental engine, which forms a unit power plant with the Warner gearbox, and the new Hess floating axle used in the 1917 Paterson

Solid Engine Support

Suspension of this engine in the frame is by means of arms extending out from the flywheel housing at the rear, and by hanging the front end of the crankcase from a forged crossmember which is bowed upward to allow the forward end of the motor casting to pass beneath it. Thus, while a three-point suspension in the accepted sense is not used, its advantages are obtained, and at the same time the engine is very solidly carried.

Three-Bearing Crankshaft

Three bearings carry the crankshaft, and three more are employed for the camshaft. On both sides of the front bearing of the mainshaft there are flanges which take any end thrust which may be imparted to the shaft by the clutch or other outside mechanism. This is a precaution against untrue running of the shaft and consequent noises. Bearings are of nickel-babbitt, being bronze-backed, and as this material is a good conductor of heat, it aids materially in keeping the bearings cool. A plunger pump feeds oil through copper tubes within the crankcase direct to the main bearings, and also to the helically-cut timing gears housed at the front.

Nothing unusual is presented in the pistons nor in the connecting-rods, both being sturdily built, and that set which goes into any particular motor is accurately weighed so that each piston and rod assembly is of the same weight as the rest, a big factor in reducing vibration and consequent smooth running.

The pump and generator shaft on the right is also utilized to drive the fan, through a flat belt connection. The fan is a four-bladed pressed-steel affair, supported by a rocking bracket which seats in a hole cast in the front end of the cylinder head plate. Moving this bracket up or down takes care of the belt tension as required. The centrifugal water pump is located ahead of the generator unit, and it delivers the water to a single opening into the cylinder block, which is directly above the pump, thereby reducing the length of the supply pipe to the minimum and making it a straight passage. The distribution of the water within the packets is arranged so that each cylinder gets amply cooled.

Tool compartment in the left front door of the new Paterson touring car. Each tool has a pocket and the flap protects the compartment from the weather. This arrangement makes it easy to keep track of the various tools and does away with groping under the seat for them

Chassis Is Lighter

Due to the use of the open type of driveshaft without torque members of any sort, the chassis is materially lightened, and is brought up to most modern of engineering ideas. Besides the driveshaft, the only rods running back from the forward part are the two brake rods controlling the two sets of brakes. The equilizers for these are placed on the rear axle housing, with brake control rods just ahead of the axle tubes.

A slight taper is given the frame from back to front so as to properly support the body throughout its length. Yet while this frame is very sturdy, being especially strengthened by wider flanges at its center, it is quite light, and indicates that much engineering skill has been put on its layout. There is a single cross member besides strengthening given by the engine at the front and the use of a strong member at the rear. This intermediate member is located at about the center of frame length, where it is obviously of most advantage. Attached to the rear member are brackets which serve the double purpose of supporting the gasoline tank and holding the spare tire and rim carrier.

Equipment Is Complete

The car is equipped with Stewart speedometer, extra rim, full tool set, one-man top, attractive universal-acting windshield, quick adjustable side curtains, and Willard storage battery. In connection with the tool equipment, special attention should be drawn to the handy arrangement of these necessities in a compartment in the left front door, close to the driver's hand. Here each tool has its own pocket, and the arrangement is an incentive to keep the tools where they belong.

Homer Laughlin Light Eight

Front Drive by Chains to Jackshaft, Friction Transmission and Double Cantilever Rear Springs Are Featured

AN eight-cylinder light roadster will be the 1917 offering of the Homer Laughlin Engineers Corp., Los Angeles, Cal., which is that city's only passenger car factory.

For more than 2 years the engineers of the corporation have been working on the car which has been placed on the market to sell at $1,050. The car is known as the Homer Laughlin eight. It is a front-drive creation equipped with a 25-hp. engine, designed and built at the Los Angeles factory of the company. The car has a friction transmission.

10,000 Miles in Tests

Three experimental models were put out by the new factory before the engineers were satisfied. After the third model had been driven approximately 10,000 miles in tests, all over the California and Arizona deserts and through the Sierra Nevada mountains, the car was pronounced finished and the factory began building cars for the market.

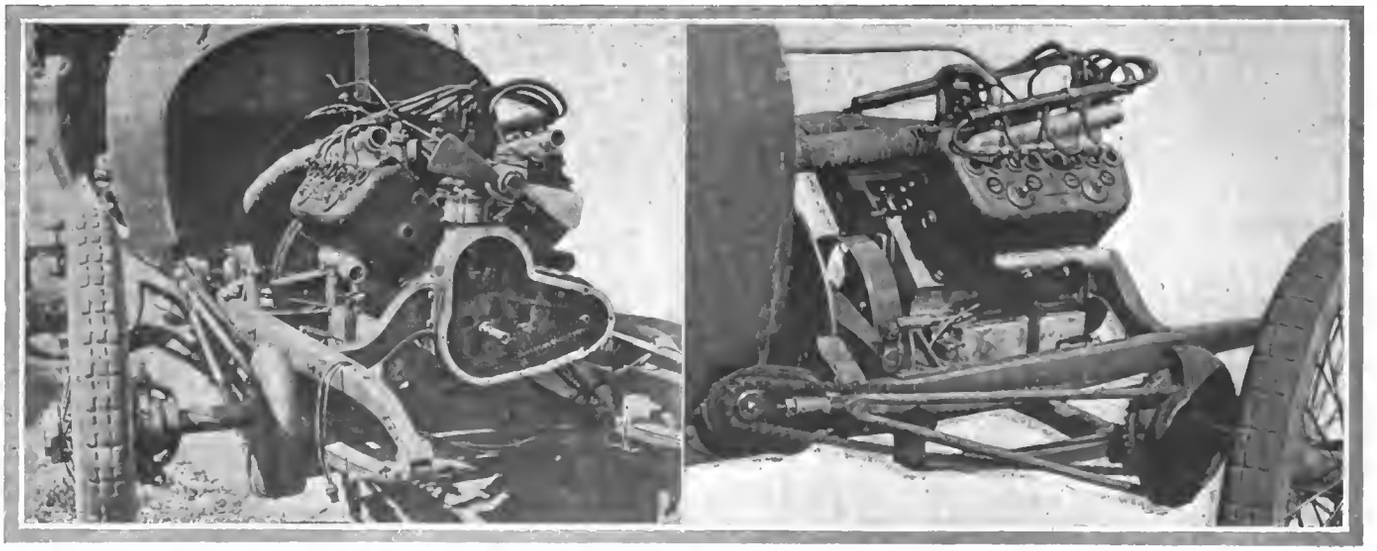
There are a number of sterling features incorporated in the construction of the Homer Laughlin eight. The body design is attractive, and on account of the dual spring arrangement, the car is one of the easiest riding machines to be found.

Front Drive by Chains

The front wheels are driven by means of chains rigged from sprockets on a jackshaft to sprockets on the front axle. The power is transmitted out to the wheels through patented universal joints which make the car extremely easy to steer, and it is impossible to lock the wheels. The drive chains are incased in a light metal housing and these are taken up or let out by means of set-screws which work on the jackshaft sprockets, leaving the front axles always in line.

Friction Transmission Features

The friction drive clutch is released by pushing down on the pedal and engaged by letting it in, like an ordinary gasoline car clutch. A powerful spring holds the drive against the disk and by releasing the spring, the clutch is released.



Front and side views of the eight-cylinder engine used in the Homer Laughlin roadster. These views also show the two-bladed fan, chain-driven timing gears and the front-drive assembly. Note the set screw arrangement from frame to axle sprocket. The patent universal joint used is visible in the illustration at the left

The friction disk is made of a composition which the engineers worked out with the intention of using it for friction disk purposes, and it is proving highly successful in the cars now in operation.

Factory Is Well Equipped

As soon as new machinery is installed the factory will have a capacity of 50 cars a month and the factory has many orders booked ahead so that the plant will be worked overtime to keep up with the demand which is not entirely local.

At the company's factory there is equipment for every kind of casting and all the machine work necessary on the cars. In the past no passenger cars have been built in Los Angeles except special models assembled in that city for racing purpoes; but the Homer Laughlin is to be built entirely in Los Angeles with the exception of the wire wheels, which are built to order by the Houck company.

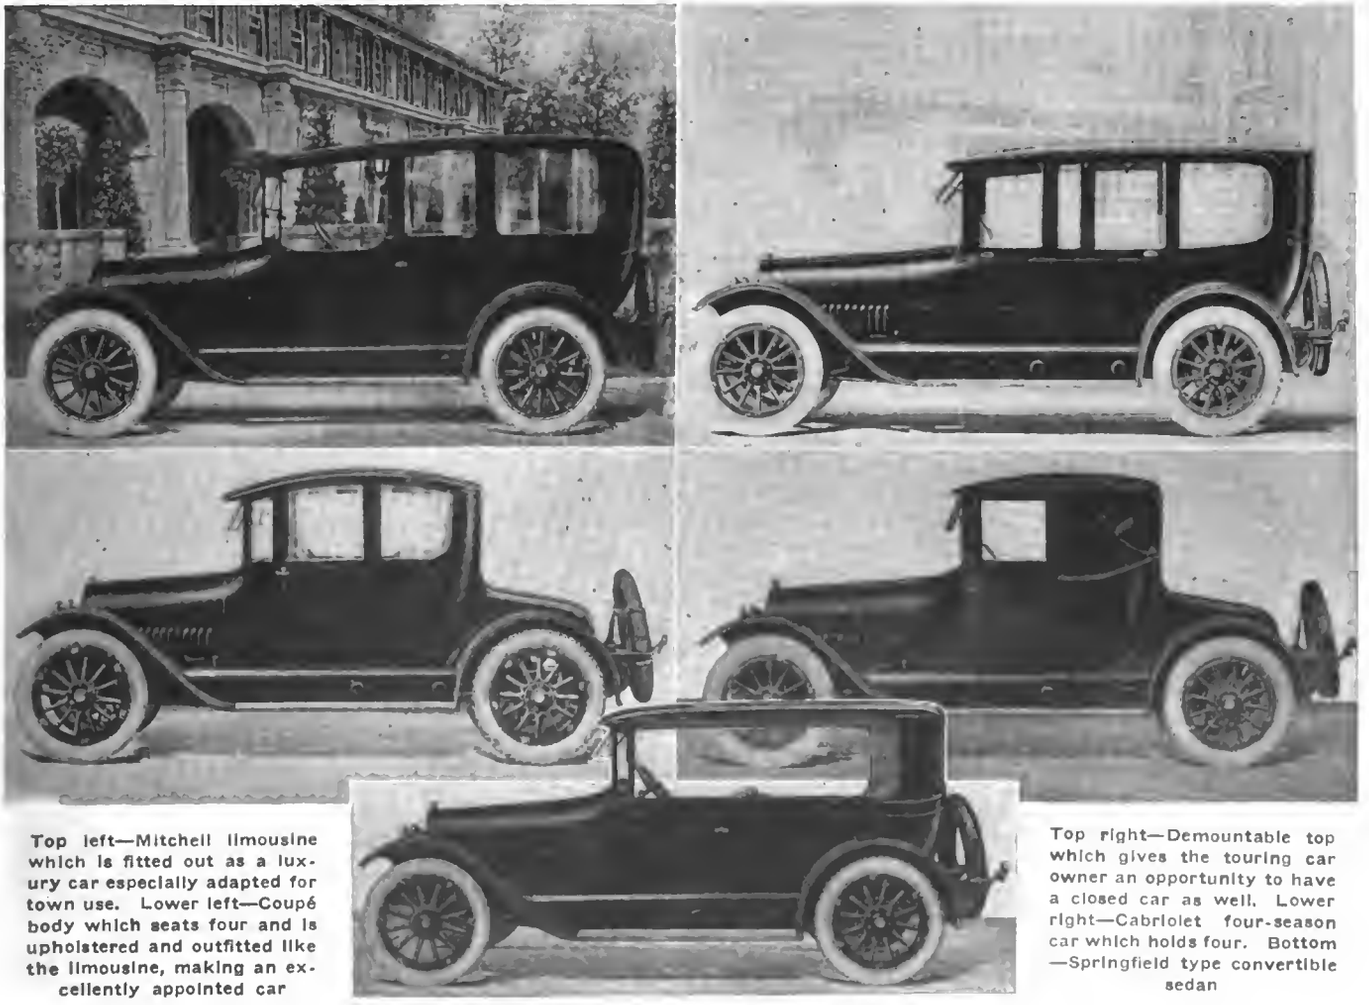
Smart Four-Season Bodies for Mitchell Chassis

THE Mitchell line of Four-Season bodies is now out and shows very clearly the trend toward bodies that can be used at all times of the year in all kinds of weather. The sedan is an especially attractive job, being a Springfield type, finished and upholstered like a high-class limousine, but with the seats all inside, so that the driver is with the other members of the party, making an ideal family car. The plate glass sides completely disappear when so desired, transforming the car into a touring design with a permanent top.

Another attractive design is the cabriolet, which should prove very popular with physicians. It has room for three passengers and an auxiliary seat for a fourth. With the top up, it is a coupé, and with the top down, a roadster. In transforming the car into a roadster, the top drops back and the side windows drop down into the doors.

For a luxury car there is the limousine which is all finished in whipcord with silk drop curtains. There are three electric lights, telephone, toilet and vanity case, flower vases, smoking sets, Waltham clock arm rests and seats that can be made to face any way.

In addition to these bodies, there is a coupé and also a demountable top that can be attached to the touring body.



Top left—Mitchell limousine which is fitted out as a luxury car especially adapted for town use. Lower left—Coupé body which seats four and is upholstered and outfitted like the limousine, making an excellently appointed car

Top right—Demountable top which gives the touring car owner an opportunity to have a closed car as well. Lower right—Cabriolet four-season car which holds four. Bottom—Springfield type convertible sedan

Effect on Industry of Standard Truck

Military Requirements in England Raise Problems of Expediency—Commercial Drawbacks Observed in Military Standard Design Made by Different Manufacturers

THE view has recently been expressed in England that the best way to get British trucks for the army is to have a standard design or series of designs and to force different automobile firms to make different parts, assembling the vehicles in some other factory. *Motor Traction* (England) makes an editorial comment on the proposal which is worthy of note in America, for similar conditions might possibly arise here, should the government decide to buy very large quantities of vehicles.

First, this editorial states that there is little doubt as to the advantage of the scheme, solely from the military viewpoint. The army would like to have all its trucks alike without variation, and is quite right in its desire to have them so, provided that there is no weak spot in the design chosen. The matter which concerns our contemporary is the effect upon the markets of the world of the existence of large numbers of these trucks for which no one firm is responsible, especially supposing that they are thrown on the used car market, as they are practically certain to be sooner or later.

The editorial continues:

"The effects of any such assembly scheme, assuming that the vehicles put together will go into a country where a very considerable potential peace-time market exists, are very difficult to assess. Viewing such schemes from the standpoint of the British industry, it is undoubtedly desirable that new and growing markets should be fed from this country in the first instance, and the goodwill connected with them thus prevented from slipping out of our hands. Very much depends on whether the cars provided as a result of official initiative prove thoroughly satisfactory in use. If they do, they will act as a useful advertisement for British industry. If, on the other hand, they are not uniformly satisfactory, harm may be done to our national reputation as motor engineers. It is always a difficult matter to design a complete chassis which will give good results without undergoing a long period of preliminary trial. The difficulty is increased when the designers have their hands more or less tied by the need of working along lines to some extent laid down in advance. It may be presumed that in any such scheme now under consideration, an endeavor will be made to utilize components readily available rather than to force the manufacturers of components to adopt new designs possibly entailing the use of fresh machine tools. Past experience, in this country and elsewhere, does not inspire very rosy hopes of the ideal character of any assembled machine, much less one assembled under such considerable difficulties.

After the War

"If, however, we take it that the endeavor to produce a satisfactory type of assembled vehicle will be successful, we have next to consider what will happen if a considerable number of these vehicles remain available for general service after the war. The official scheme of assembly would presumably only be temporary, and would not be perpetuated in competition with recognized manufacturers. The vehicles remaining on the road might or might not be retained in government service by our allies. If so retained, no doubt a considerable store of spare parts would be available from the first, and adequate arrangements would be made for the provision of further supplies of such parts whenever they might be required. If, on the other hand, allied governments were to dispose of their vehicles to traders and others when the war is over, it is quite conceivable that the time would arrive when the owners of the machines would find themselves in difficulties with regard to spares and renewals. It would be very awkward for a user to have to apply to one manufacturer for engine parts, to a second for steering gear parts, to a third for back axle parts, and so on. Consequently, it would be necessary that somewhere or other a large stock of spares should be kept in existence, until the number of official type vehicles remaining in service had become quite negligible. Without such precautions, the most well-intentioned effort to supply, by the creation of assembled cars, from this country rather than from abroad would cause more harm than good to British industry in the long run. We have never had a very great reputation for watching the interests of users of British machines in distant countries, and if we are to extend our markets effectively to absorb our much increased output, we have got to show general improvement with regard to service of this kind.

"On the whole, the arguments in favor of the temporary adoption of some assembly scheme under official auspices seem to be fairly strong, but so also are the arguments against it. If the real object of such a scheme is to be primarily to advance the interests of the British industry, and not merely to provide useful experience for a few favored individuals, there are numerous precautions which must necessarily be taken in good time. Given these precautions, no great harm may result, but on the whole we cannot express ourselves enamored of the principle involved in the creation of what might be called the national assembly chassis."

Compressed Coal Gas for Trucks

Comment has recently been made on the effects of gasoline shortage in England on the stimulation of kerosene experimentation. Another suggestion which emanates from France is to use coal gas compressed in steel cylinders, and anent this the *Motor Trader* (England) makes a very interesting comment as follows:

"Persons in touch with the self-propelled street vehicle movement of the early and middle "eighties" of last century will remember the attempts to adapt coal-gas engines of the Otto (Crossley make) type for driving street tramcars. We believe there is a surviving example of this style of propulsion at Neath in Glamorganshire, though we can only recall one of the last attempts in that direction, namely, a tentative installation at Blackpool.

"Attention having been drawn recently to the possibilities of this form of propulsion, using compressed coal gas in cylinders easily removable for recharging and replacement, it may be useful to append some data contributed in 1913 by a French gas engineer to the Proceedings of the Institution of Gas Engineers of France.

"Owing to the exceedingly high degree of compression which the gas undergoes—over 100 atmospheres—certain of

the heavy hydrocarbons, such as benzine and its homologues, are thrown down in liquid form, thus causing a direct loss in thermal value of from 6 to 10 per cent. Taking the average price of gasoline at 42 cents per gal., its calorific power being about 140,000 B.t.u., it is seen that approximately 80,000 B.t.u. are obtained for 24 cents. On the other hand, assuming the average calorific value of the compressed gas to be about 480 B.t.u. per cu. ft., with this selling at 72 cents per 1000 cu. ft., including compression, the thermal units obtained for 26 cents would be 160,000. It is suggested that ten gas cylinders could be carried on each vehicle, these being 6 ft. 6 in. long by 8 in. in diameter, and involving a dead weight of about ¾ ton. Between them they would carry about 2500 cu. ft. of gas, or the equivalent of about 11 gal. of gasoline in the case of gas as obtainable in Paris.

"It may be inferred from these figures that the prospects of coal gas are not great for vehicle use, and that without reference to the effect to be anticipated from substituting a calorific for a lighting standard of efficiency, as recently sanctioned by Parliament."

Westcott Adds Springfield Touring-Sedan Body

THOUGH built under the Springfield patent, many improvements have been incorporated in the new Westcott Touring-Sedan body. The only windows that it is necessary to entirely remove are those at the sides of the rear seats, as the others telescope into the sides of the body. There they are completely hidden. The pillars, too, fold down and are concealed in a similar manner.

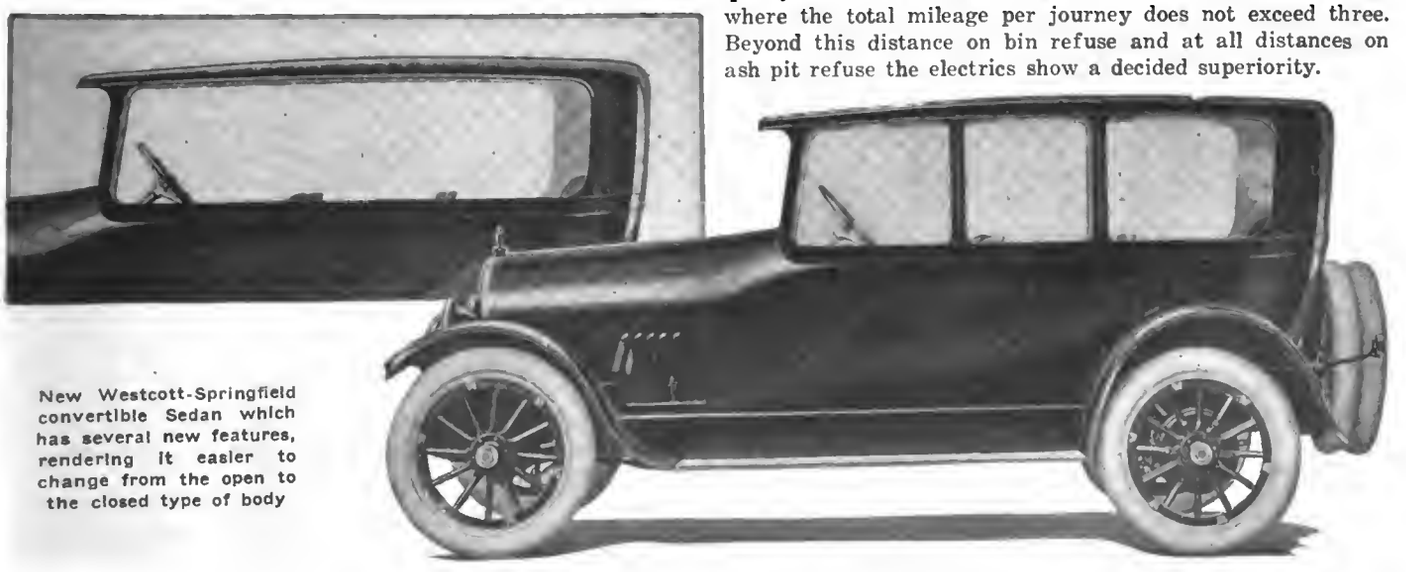
The windows at the sides of the rear seat, however, may be dropped three-quarters of the way into the sides of the car for the purpose of ventilation, and the other windows may be lowered to any desired point.

This body type is built on the standard 125-in. wheelbase chassis. This has a Continental 3½ by 5¼-in. motor with an S. A. E. rating of 29.4 hp. A Fedder's radiator with thermostatic control comprises the cooling system, the latter tending to better the performance of the motor. A few of the other specifications of this model include a two-unit Delco system, Spicer universal joints and Timken axles and bearings. The rear springs are made from chrome-vanadium steel and are of the cantilever type.

The aisle between the front seats has been widened to 9 in., and the rear seats have been made correspondingly wider. The rear seats now measure 50 in., instead of 47, as was the practise last year. The generous leg-room, both in the front and rear compartments, has been maintained, and the cars are more attractive than heretofore.

It is predicted that this season will see a considerable improvement in the all-season and all-weather types of bodies, as the trend which started about three years ago has been carried through until some sort of a convertible body is incorporated in practically every line. The Westcott-Springfield types illustrated on this page show one direction that the development is taking, in that the conversion from a summer to winter type is easier made by a person who is not a mechanic.

To combine the utility of the convertible job with sightliness is one of the hardest tasks that confronts the designer of this type of body. This has been met very successfully in some of the newer types that are coming out this season. The Westcott bodies have some of these developments, as they have been worked out in their own plant, and the improvement is marked. The prices at which these bodies are sold are also low enough to make all-year motoring more attractive than it was when it was deemed necessary to have two cars, or at least two entirely separate bodies which could be interchanged.



New Westcott-Springfield convertible Sedan which has several new features, rendering it easier to change from the open to the closed type of body

Electrics Cheaper than Horses in Garbage Haulage

THE street-cleaning department of Sheffield, England, has found electric vehicles to be more economical than horses in hauling garbage. The cost per ton of refuse collected showed in practically every case a marked advantage on the side of the power wagon. Two vehicles have been in operation for some time. Taking a period of 22 weeks one electric vehicle working during daylight cost $1.41 per ton of refuse collected. For a corresponding time under similar conditions the cost of the horse was $1.83 per ton. For night work the cost of the electric vehicle was 56 cents per ton and for the horse 79 cents.

On the second vehicle on another kind of service the cost was $1 per ton as compared with 93 cents for the horse system, while at night on this same service the cost by electric vehicle was 25 cents per ton as against 62 cents for the horse. The tests have led to the conclusion by the municipality of Sheffield that horse labor shows an advantage where the total mileage per journey does not exceed three. Beyond this distance on bin refuse and at all distances on ash pit refuse the electrics show a decided superiority.

Truck and Tractor Engines—Part II

Establishing a Rational Basis for Motor Application—Details of Design of Crankshafts, Valves, Bearings, Flywheels, Connecting-Rods, Camshafts and Pistons

By H. L. Horning
Engineer and General Manager Waukesha Motor Co.

MANY formulas have been put forth for establishing a rational basis for motor application based on M.E.P. obtainable in engines and many attempts to use these formulas up to this time have failed because there are so many variables and designers have had little experience in applying them. American conditions vary so much, as quantity manufacture dictating standard models in trucks to cover a wide range of conditions and make it seem advisable to hold to what has been found good practice. Engine designs and sizes have varied widely in the past; present practice finds engine design and sizes converging toward common practice.

Truck and Tractor Engine Specifications

The following specifications represent what appears to be good practice in engine design and material for trucks and tractors. This was arrived at after examination of all foreign and American specifications available for successful trucks and their engines and American practice in tractors:

Cycle—four.

Number of cylinders—four.

Cylinder type—in pair or cast in block—L head or valves in head.

The L head seems to be less sensitive to ignition troubles and most commonly used, though the valve in head has decided theoretical as well as actual points of excellence.

Material—Semi-steel.

Elements of design—Cylinder design for truck and tractor motors is mostly involved in an efficient combustion chamber, for it is here that the basic process of the motor occurs and where most defects are evident. Perhaps the difficulties may be best illustrated by stating that at full load and with poor fuel such difficulties as compression pound, cracking of fuel, steaming of waterjacket and pre-ignition occurs. A typical case may be cited of a pleasure car engine, by means of a preheated intake manifold, burning either a poor fuel or kerosene and delivering full load. But under these conditions the following bad symptoms occur:

(1) The exhaust is not clear, being light-colored or steamy.
(2) The engine is pounding excessively.
(3) The power is off at least 20 per cent.
(4) The water outlet from engine is boiling.
(5) Fuel economy bad.

A thorough examination will show the combustion chamber as having a hot spot—most likely a valve plug, a spark plug or a part in the neighborhood of the exhaust valve.

It is important to remember that 70 per cent of the heat loss to jacket water occurs in the neighborhood of the exhaust. To locate the offending spot it is well to start with valve plug, and a very striking demonstration will occur if this is causing the difficulty.

With an oil can keep the plug under water so that it will boil violently and cool the spit.

In about 30 sec. the exhaust changes and becomes almost invisible, the pounding stops and the power-output goes up, the magneto can be slightly advanced. Economy improves and the outlet water ceases to boil.

As nearly as we can tell, this is what happens:

1—The hottest spots have been so cooled that cracking of the fuel which comes in immediate contact with the spot has stopped, as indicated by the clearing of the exhaust.

2—The spot has so cooled that circulation water can come in contact with the walls nearest with the resultant proper dissipation of heat.

3—Pre-ignition has ceased, because the temperature of the hottest spot has been brought below ignition temperature.

If now we cease cooling the hot plug all the old processes will have gone through various stages of development in about 2 min. and the engine will start working as at first, which proves conclusively the source and cause of the difficulties. If the hot spot be a valve or the center of a piston, it can be ascertained by the color of the metal toward the center.

Generally speaking, we have recalled by this demonstration the following principles:

1—The maximum temperature of any spot in the cylinder must be kept below the pre-ignition point.

2—The maximum temperature of any spot in the cylinder must be kept below the cracking point of any part of the fuel.

3—Any one spot will determine the performance of the engine.

4—That one spot capable of cracking fuel or pre-ignition spreads over an area and causes so-called steam pockets in the circulation which further extends the disturbance in the performance.

5—Economy of fuel consumption is established by a high average temperature of combustion chamber walls.

6—The limit of practical compression, hence power, output, economy and of fuel quality which can be successfully burned is established by a high average temperature of the combustion chamber and low maximum temperature of the hottest spot.

Crankshaft Design

Crankshaft diameter 0.45 to 0.50 of cylinder diameter. It should be heavy and short with long cheeks. Material, 40-45 carbon steel; heat-treated to give ultimate strength of 90,000 to 100,000 lb. For heaviest service chrome nickel or 3½ per cent nickel steel, 0.35 carbon heat treated for ultimate strength of 140,000 lb. per square inch. These crankshaft sizes and specifications mentioned are for three-bearing shaft. Bearing lengths as follows are according to common practice: Connecting-rod bearing length may be put down as 0.65B. Making this unity, then the length of main bearing is as follows: Front end, 1.20; middle, 1.15; flywheel end, 1.50. Tabulating service experience and analyzing actual pressures the following has given better results: Front end, 1; center, 1.40; flywheel end, 1.50.

The importance of the center main bearing is illustrated by the constant attention it requires when of normal length.

Where two-bearing cranks are used, the same general specifications obtain with the exception that the shortening of engine as much as possible is desirable to develop the stiffening of the crankshaft. Inasmuch as the valves govern the engine length and that with a given lift effective valve areas vary directly as their diameter while displacement drops approximately as the cube of the diameter, shortening of the smaller sizes of motors is easily obtainable. General experience with two-bearing shafts suggests that nothing short of counter-balancing will correct the whip and lack of stiffening in shafts having common dimensions. Crankpin and main-bearing sizes should be not less than 0.70 B. The stiffness of the shaft should be conserved by attaining bearing area through the large diameter of the shaft rather than by length and by getting the greatest longitudinal thickness of cheeks possible. The connecting-rod bearings should be 0.6 B length; end cheek 0.42 thickness, while the long cheeks should be 0.6 B.

Number of Bearings

Some recent designs have gone to four and five main bearings. The four-bearing shaft should give satisfaction but make a long engine; a five-bearing shaft makes a still longer engine and robs the connecting-rod length to give length to crank bearings and have been mostly found inferior in general all-around results to a well designed three-bearing shaft. In designing the severity of service compared with usual provisions made to meet it, make the order in which bearings need attention as follows: 1, Crank pin; 2, center main; 3, flywheel end; 4, front end.

Crankshafts do not wear cylindrical, the greatest wear coming on the inside of the crankpin and on the opposite side of the main bearing. The use of alloy steel in cranks is justified only by the desire to retain the true form of journal for a reasonable length of time. Alloy steels and particularly chrome-nickel variety have shown admirable ability to withstand abrasion but, roughly speaking, the elastic limit seems to give a measure of resisting ability of the material, other things being equal.

The factor which seems to determine largely the quality of the crankshaft material is most readily expressed by the saying that "crankshafts must last in spite of the oil they are apt to get in truck and tractor service."

Notwithstanding the poor initial quality of oil that engines get, the lubricating quality is still further reduced through the rapid increase in gasoline or kerosene content covering a 10-hr. run in tractor service. Where open-type breathers were used, the writer has seen ½-in. of mud and sand in the bottom of a crankcase and has seen leaves taken out after 3 months' service. In this particular case the crank was found to have worn 0.003 average, while the cylinders wore 0.030; piston rings were worn to a knife edge and width of ring grooves to 0.030 clearance on side ring for top, 0.018 clearance for second ring and 0.005 for bottom groove. This cannot be considered a reasonable condition under which a mechanism could be expected to work, but the demands are such in tractor service that the motor that receives little damage should conditions get bad, certainly illustrates the old law of the survival of the fittest. Dust in the combustion chamber can be eliminated by various methods of dust removal, the most successful type being one made by a well known carbureter company.

Dirt in the crankcase can be kept to a minimum by the use of a check-valve breather which allows pressure to escape but checks the flow of air into the crankcase.

Lowered lubricating value of oil due to fuel leakage passed the rings can only be eliminated by removing oil every few days, filtering same carefully, distilling off the gasoline and kerosene and using the remaining oil half-and-half with new oil; or by the old methods of force feed oil leads to each cylinder and bearings.

It is almost universal practice to attach crankshafts to flywheel with a flange at least two and one-half times the diameter of crankshaft. Numerous methods are adopted on crankshafts to prevent oil from leaking out both front and rear end of the crankcase. Practice has not converged to any one method.

Valves

Valves—Clear diameter = 0.45 B. to 0.50 B.
Type of valve—poppet.
Material—High carbon alloy steels hardened all over.
Type of seat—45 deg. angle.
Valves inclosed.
Piston pin—hollow.
Material—0.20 carbon steel, case-hardened and ground and polished.
How held—either to piston or in connecting-rod.
Type of bearing—bronze.
Valve tappet—Mushroom or roller type. All wearing surfaces case-hardened and ground.
Timing gears—Crankshaft gear 0.30 carbon steel.
All others—Semi-steel.
Teeth not less than 8 pitch helical.

Crankcases

Crankcases whenever possible should be of aluminum with 8 per cent copper, commonly known as No. 12 alloy—firstly, because of its lightness; secondly, because of the rapidity with which it can be worked, and, thirdly, because of its high heat conductivity.

The design of crankcase usually revolves about the question of rigidity and that crankcase is the best which is the stiffest and the best conductor of heat. Usually the problem of compromise comes, in sacrificing stiffness to provide for a door into the crankcase for inspection. This can be met by making the doors oval rather than rectangular. Through bolts should be used wherever possible, and where aluminum is used, thread lengths should not be less than twice the diameter, and washers should be provided under the bolt heads and nuts that will distribute the pressure over as wide an area as possible, the area of washer to be three times the area of the bolt if possible.

In larger engines the crankcases are split horizontally, while in two-bearing crankshafts the barrel form of crankcase produces a very stiff case. A very stiff form of crankcase is that in which cylinder and upper case is cast in one. Combustion chamber should be formed in a removable head which, aside from the effective holding of the gasket, presents no serious problems but makes an admirable design for truck and tractor service.

Bearings

Bearing design, especially for connecting-rod crank end, is almost universally of high tin babbitt alloy in a comparatively thin layer backed up by various designs of backing held to the bearing material by tinning and other mechanical means. Great pains are now being taken to have accurate fits between connecting-rod and back of bushing to insure rapid heat dissipation.

Main-bearing bushings are held to the crankshaft case with accurate fit, but experience has taught that the better heat conductivity of the crankcase is such that die castings are used, if of good design and the same bearing material as the connecting-rod bearing.

One of the most difficult parts to hold is a bearing bushing on the crankshaft and especially the connecting-rod bearing. Brass screws are usually used to hold the bearings in place for assembling but are never sufficient for working conditions. For motor running up to the limit, great care must be taken to make the take-up shims assume the roll of keys and sufficient bearing on the shims and bushing must be pro-

vided to hold everything firmly in place without undue wear. A solid shim is the best, but few users can take up bearings except by removing their shims. Laminated shims are being used to a greater degree.

Flywheel Design

Experience has taught that a flywheel having a stored energy of 30 per cent more than is usual in passenger car service is a positive benefit in truck service and a great protection to the engine. Likewise, tractor engines should have about twice the stored energy that trucks have, this being figured at the average speed of passenger car engine against the speeds of maximum torque for truck and tractor engines. This is seldom attained in service up to this time, owing to limiting dimensions in the design of trucks and tractors.

In trucks, clutches have been converged down to three types, these being the cone, plate and multiple disk. This has determined the flywheel design to a large extent.

There is one fundamental difference between truck and tractor clutches. A truck clutch is engaged when the foot is off the pedal; while in tractor service the clutch must be engaged or disengaged or left in either condition while the foot is off the pedal. The most common tractor clutch is an expanding shoe clutch, counter-balanced, easily removable in part or whole without disturbing other parts of the tractor.

Connecting-Rods

These should be made of 0.35-0.45 carbon steel, heat-treated for an elastic limit of 70,000 lb. per sq. in. The design should be absolutely as light as possible. Recent investigations show that prevalent rod design is 33 per cent too heavy. While not always necessary, the trade demands four bolts in the crank end. These make adjustment of bearing more difficult. No doubt with stiffening of crank shafts, shortening of bearings with increase in diameter will brink back connecting-rods with one-bolt construction.

Bolts are of alloy steel, heat-treated to a strength of 120,000 lb. elastic limit.

In truck and tractor engines, the desirability of having rod bearings in line with the piston center is greater than in passenger cars. Connecting-rod length must be twice the stroke.

Camshafts

Camshafts in truck and tractor engines are different from passenger-car camshafts in that they are subjected to harder service and must be designed so that the surface on the cams and bearings will have ample area; in fact, more by 0.25 per cent than in automobile practice.

Camshaft material is usually 0.20 carbon steel, case-hardened and ground.

The timing on truck and tractor engines is very close to passenger-car engines, the main difference being in the closing of the intake. This is earlier than on passenger-car engines, due to the fact that maximum speeds of touring require higher motor speeds than those of truck or tractor service. Ability at lower speeds is very desirable in commercial service.

The bearing areas for the bearings in a camshaft based on satisfactory service are as follows, with cylinder area as unity, A:

Gear end, 0.20 A.
Center bearing, 0.30 A.
Flywheel end, 0.15 A.

Pistons

Pistons are usually made of semi-steel and are generally too heavy. Between 3½ and 5¼-in. bores pistons should not weigh over the amount indicated by the formula

$$W = 0.05\ B\ 3 \text{ lb.} \qquad (4)$$

This weight in the smaller sizes is entirely within the skill of foundry and machine-shop practice and these are the governing factors. One shop is now in quantity production in which piston weights are 10 per cent lighter than indicated by the formula.

The influence of piston, connecting-rod, piston pin and ring weight on the life of connecting-rod bearing is so definitely settled at all speeds that no designer can afford to have one grain more weight than necessary on any one of these parts.

No tendencies seem to be shown toward aluminum pistons in commercial engines, though it may be very much of an advantage to have a piston whose structure is aluminum, with bearing surfaces of some better material. Tractor pistons, because of the higher temperature at which they work, must have more clearance and this is also true of the gap in the ring. The following formula gives results of wide experience and has the advantage of being satisfactory for the following range of work:

Truck engines, light or heavy service, burning gasoline.
Tractor engines, light or heavy service, burning gasoline.
Truck or tractor engines, kerosene work.

$$Cs = 001\ B$$
$$Cm = 003\ B - 0.005$$
$$Ct = 003\ B$$
$$Ro = 003\ B$$

In which Cs is the clearance in diameter at the skirt, Cm clearance at the land between the top and second ring, Ct being the clearance at the top land; Ro opening of ring in a standard size cylinder at room temperature.

It must be said that the clearances indicated above presume an efficient system of lubrication and cylinder wall cooling. It must be urged that details of design in piston and cylinder such as good engineering will recognize also govern the clearance.

The piston ring fits and sizes recently adopted by this Society represent the best practice.

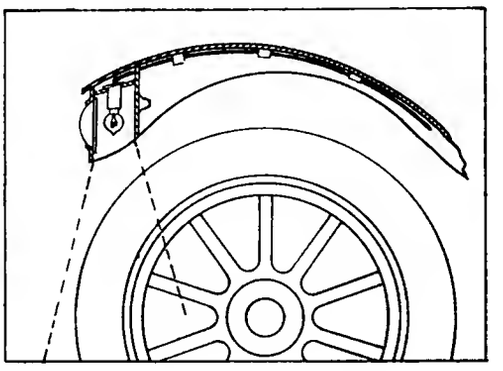
Inasmuch as the greatest friction losses in an engine are due to the piston, it is important that the piston have ample means of conveying and distributing oil along the cylinder. Usually three oil grooves are provided and a relief in the center wider than the piston pin drain is carried.

In the larger sizes, or from 5-in. up, cooling ribs are placed under the head running down the side of the piston. In some engines pins are cast in the head of the piston to facilitate cooling by oil.

A practice is becoming commoner of having a taper on the top land of the piston to insure an oil pocket or seal, so to speak, for the surplus oil pushed up by the piston and ring. While no definite proof has been found that this is superior construction, yet engines having the taper are giving superior heavy-duty service.

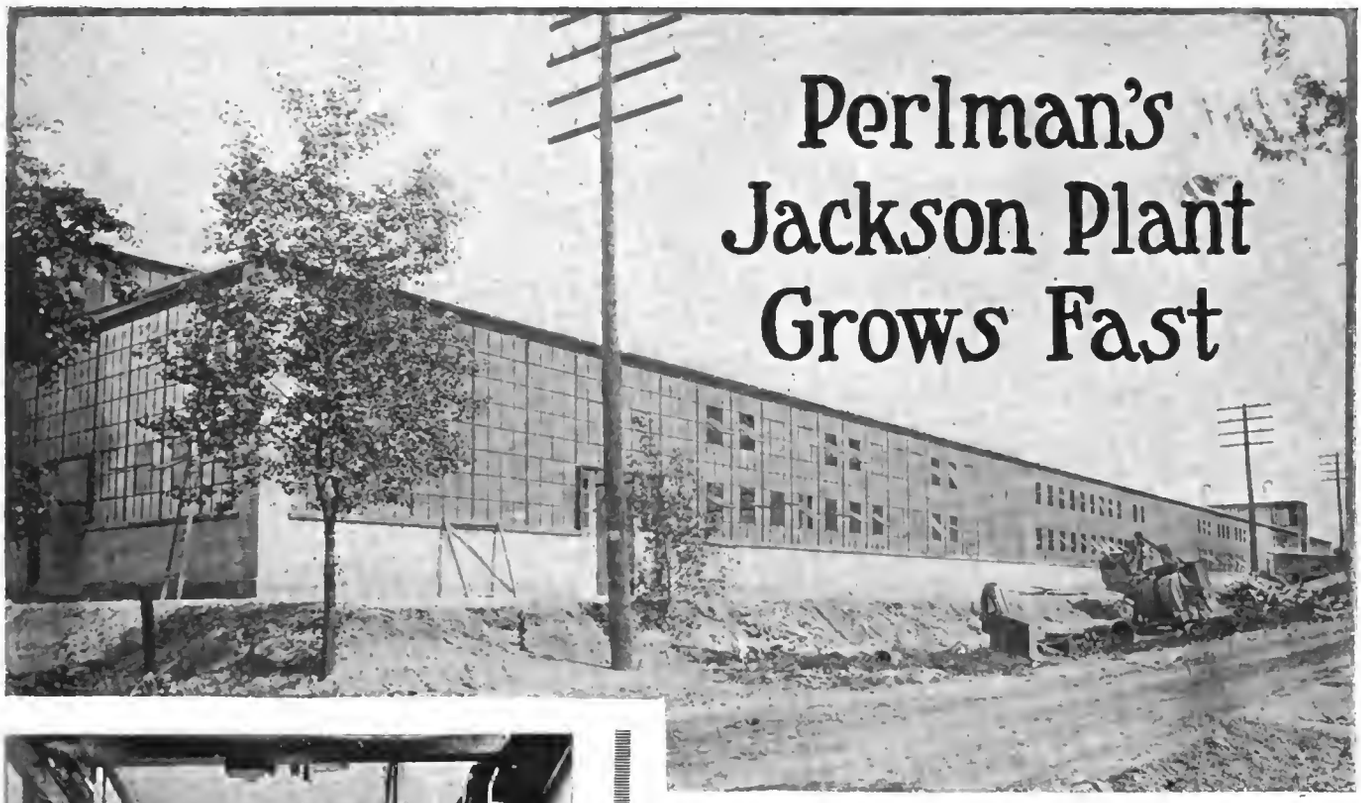
(To be continued)

A Sidelamp That Lights the Tire



An ingenious side lamp design recently patented by E. D. Shaw, Syracuse, N. Y. It throws a light ahead and also illuminates the front tire, which is a great convenience when driving into a garage or in city traffic

Perlman's Jackson Plant Grows Fast



Perlman Rim Corp's. completed plant at Jackson, Mich.

Finishing the floors and ceilings in record time

Ready for the final touches, Perlman rim plant in Jackson, Mich.

IT took 2 months and 14 days to put up the new plant for the Perlman Rim Corp. in Jackson, Mich. Thursday, April 6, the Austin Company got word to go ahead on a new building for this corporation at Jackson, Mich., 100 ft. wide by 320 ft. long. The complete structural steel for the job was there April 10, 4 days after the contract was signed. Before going ahead it was necessary to build 1300 ft. of railway siding, and there had to be a lot of shovel excavating before the sidetrack could be put in. Thursday, April 13, the Austin Company's steam shovel was on the job. Seven thousand yards of material had to be excavated. Monday, April 24, the lumber for purlins and roofing was on hand. Wednesday, May 3, they started steel erection, and Wednesday, May 10, 300 ft. of the steel was up complete. The roofing was very close behind when the completion of the brick work for the walls was more than half done.

The time in which the brick, steel sash and roof work were completed is exceptional. On June 1, all the main structural work, together with the steel sashing and wood roofing, was complete. Ten days more completed the composition roof and concrete flooring and by June 15 the glazing was done and a hemlock sub-floor added 2 days later. The maple flooring for the top was completed June 20. Thus in 19 days after the structural work was finished, the entire job was terminated.

Standardized Industrial Building

The building was done by the Austin Co., Cleveland, Ohio. This concern makes a specialty of standardized design, quick delivery industrial building. The Torbenson Gear & Axle Co. is having one of these standard buildings erected at a cost of $20,000. It is to be completed in 30 days and to be then ready for the manufacturer of passenger car and commercial vehicle axles.

The Rostrum

Correct Timing for a Hupmobile 20

EDITOR THE AUTOMOBILE:—What is the correct timing for a Hupmobile model 20? The engine has new rings with good compression. Maximum speed of car 20 m.p.h. and has not enough power to pull a 1 per cent grade on high. Evidently something is wrong. What carbureter would be good for this car? On the level the car will roll easily.

2—Why does not the battery ignition, for instance Delco, have a safety spark gap like the magneto to protect the windings? I refer to the true high tension.

3—Has Rickenbacher a foreign or American engine in his Maxwell?

Dayton, Ohio. H. A.

—The simplest manner of timing a model 20 Hupmobile motor is to turn the motor over by hand until No. 1 and No. 4 pistons are at extreme top center. With the crankshaft in this position, turn the camshaft over until the exhaust valve of No. 4 cylinder is just closing and the intake valve on No. 4 just opening. You will find there is a slight distance to travel between the moment that the exhaust valve closes and the intake valve opens. We would advise setting the camshaft as near the center of this distance as possible. Should you find it necessary to move the camshaft gear one-half tooth one way or the other in order that the gears may mesh properly, we would suggest that you retard the camshaft gear the necessary one-half tooth.

In setting the ignition we would advise that the magneto should be set so that the points in the breaker box should separate when the motor is 5/8 in. past the dead center flywheel travel. In other words, while the motor is in the position that it is when you finish timing the valves, turn the crankshaft so that you have 5/8 in. past the dead center line mark upon the flywheel. Then the magneto should be set so that the points in the breaker box are just breaking with the distributer brush, making contact with that terminal which leads to No. 1 cylinder.

A great many mechanics who are well acquainted with that type of spark which can be advanced and retarded will time the model 20 Hupmobile engine so that the spark will occur before dead center is reached. When this is done you will find that it will be practically impossible to obtain any power from the engine. Do not time this set spark type of magneto before dead center.

If the adjustments are properly made upon the Breeze carbureter you will obtain excellent service.

2—Battery systems have safety spark gaps in the high-tension coils.

3—The motor in Rickenbacher's car is American built.

Knocks Below 8 M.P.H.; All Right Above

Editor THE AUTOMOBILE:—I have a Buick D-45 1916. When I run it below 8 or 9 miles there is a knock in the engine. It is equipped with a Stromberg carbureter which I get from 17 to 18 miles to the gallon of gasoline. The engine works well above 8 or 9 miles.

Grant, Mont. J. N. M.

—It is probable that this knock is caused by one or more of the cylinders missing at low speeds and it may be that in installing the new carbureter this has been so adjusted as to cause this missing. It might be that a change in the adjustment of the carbureter will cure all of the trouble. If this does not do it no doubt the location of the cause will be found in the valves or ignition.

Sometimes it happens that a valve does not seat all the way, causing the motor to misfire in the same way as it would if the valves needed grinding. This may be due to too close an adjustment in the clearance. A misadjustment in the ignition will give the same kind of trouble. The timing should be set so that when the spark lever is in full retard position the spark occurs on upper dead center.

In all probability, though, the trouble will be found in the carbureter which is providing, in all likelihood, too lean a mixture at low speeds. The fact that you are getting as high an economy as you are may also signify that the setting is a little too lean.

Ammeter Probably in Damaged Condition

Editor THE AUTOMOBILE:—I have equipped my 1914 model Hudson six-40 with a model 301 Weston ammeter, with the following results: The ignition current goes through the instrument and does not seem to be as good as before. The lights do not burn as brightly, for if I place a screwdriver across the two terminals on the outside of the motor generator the lights immediately brighten up. Kindly advise me how to remedy this and still get a charge and discharge reading.

Richmond, Va. J. L. V.

—It is quite difficult to account for your trouble unless the instrument has been connected in circuit improperly at some time and the heavy current that is required for starting the engine has passed through it. The model 301 instrument is not intended for such service and might be badly injured if not wholly destroyed if such a connection has been made. Without knowing what terminals you refer to on the generator it is hard to explain what the effect of short-circuiting them will be but it is quite possible that other parts of your circuit besides the ammeter may be giving trouble. This refers to such things as brush contacts, cutout relays, etc.

Had to Make 75 M.P.H. at Omaha

Editor THE AUTOMOBILE:—What were the qualifying speeds of the cars in the Omaha, Neb., race of July 15, 1916?

2—What causes a 1916 Mercer motor to knock after the carbon has been removed and valves ground?

Flemington, N. J. O. M. V.

—At the Omaha race the cars were required to make a lap at an average speed of 75 m.p.h. before being allowed to compete.

2—There are a great many other causes for a motor knocking other than carbon and valves. Any loose part throughout the moving elements of an engine may be responsible for a knock. The most common causes are in loose bearings at either end of the connecting-rods, loose main bearings, worn pistons, etc. The camshaft bearings are sometimes responsible for a knock which cannot be found in any other

part. The bearings at each end of the connecting rod are the most common sources. If you would give more data regarding when the knock occurs and regarding its sound it would be easier to aid you in tracing the trouble.

Installing Ammeter on Hudson 54

Editor THE AUTOMOBILE:—Would you please inform me if it is possible to install an ammeter on a model 54 Hudson? If so kindly furnish a wiring diagram stating how the installation is made.

New York City. J. E. S.

—It is possible to install an ammeter on the model 54 Hudson and the manner in which the work is carried out is shown in the accompanying wiring diagram, Fig. 1. Remove the existing wire from the cutout terminal *A* and attach to one of the ammeter wires at *B*. The other wire from the ammeter is then connected to *A*. Should you notice that the ammeter reads "Charge" when it should read "Discharge," change the terminals about.

Full Retard on Top Center Position

Editor THE AUTOMOBILE:—What is the quickest and best way to find out whether a 22-72 Mercer engine is correct as to magneto setting? That is, if it is firing when it should. In other words, what is the best way to set the magneto?

2—Does the spark in a magneto occur when the points are together or just breaking?

Oshkosh, Wis. L. W. H.

—The magneto should be set so that in full retard position the spark occurs on upper dead center.

2—The spark does not occur until the instant that the points separate. It is the separation of the points which are in the low tension circuit that induces the current in the high-tension circuit. Therefore, no current is flowing to the high-tension circuit until after the breaker points are separated.

The reason for the spark being set at upper dead center at full retard is that a later spark than this is never required. When the engine is turning over very slowly, requiring the latest possible spark, if the setting is such that it occurs on upper dead center, the engine will not knock because before the spark could have taken place and ignited the gases the piston will have passed over the dead point and be again on its way down.

Engine May Be Loose in Frame

Editor THE AUTOMOBILE:—The distinctive clink commonly known as carbon knock developed in my motor and I had the carbon burned out. This did not seem to improve matters very much as the knock still occurs when the accelerator is depressed. Occasionally, while on the road this will cease for an hour or two and then recommence without my having touched anything. The trouble is less pronounced when the motor is very hot, as after a stiff climb. What can be the cause of this?

2—When running on first or second speed the gears make a terrible noise. At times, for no apparent reason, they can scarcely be heard. The trouble here seems to be connected with the engine trouble mentioned above as the two occur at the same time. Can you state the reason for this?

New York City. W. G.

—Your two questions seem to run together and give a clue to the nature of the trouble. It certainly would seem from what you submit that the engine is misaligned in the frame or loose. At times the alignment may be correct, thus causing the gears to act silently, whereas, at another time, the engine may become dislocated, throwing everything out of line, causing the knock you speak of as well as the growl in the gears.

It is suggested that you look into the fastenings of the engine to see if any of the bolts have loosened.

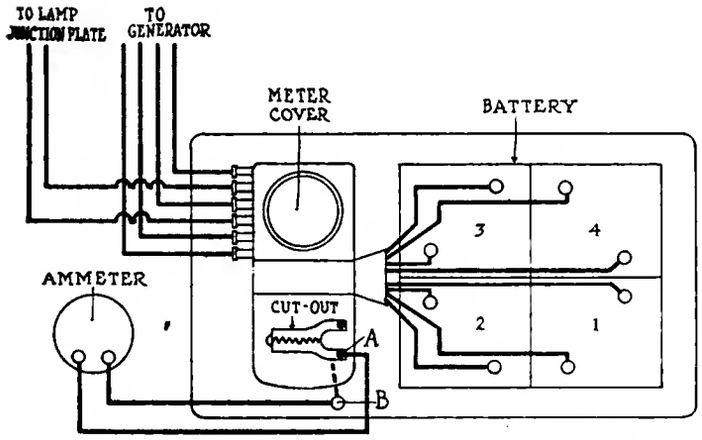


Fig. 1—Wiring diagram showing method of installing an ammeter on a Hudson model 54

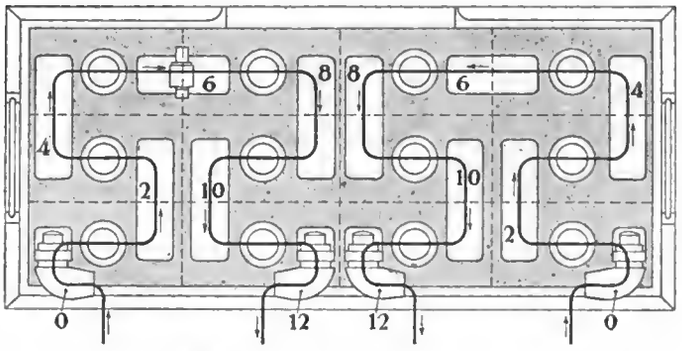

Fig. 2—Wiring diagram showing voltages and cells of battery in U. S. L. electric system used on Rambler cross-country and 1913 Oakland

Diagram Showing Voltages in U-S-L System

Editor THE AUTOMOBILE:—Kindly give wiring diagram showing voltages and cells of battery in the U-S-L electric lighting and starting system on the Rambler cross-country car and the 1913 Overland.

2—Kindly advise whether or not the electric lighting and starting companies would furnish various wiring diagrams of their wiring system by writing for them.

Trinidad, Col. W. H. O.

—While it is not quite clear what wiring diagram you desire, it is probable that you wish the diagram of the U. S. L. type EL-1207 battery which was used on these cars. This is given in Fig. 2. The cells are marked off on the battery by dotted lines, and the current is traced through the battery when discharging by the full lines with the direction of the current indicated by arrow heads. The cells are assembled in two separate groups of 12 volts each and on each length is marked the nominal voltage with relation to the negative terminals of the group in which it is contained. It is important to note, in connection with the voltage readings of the batteries, that this varies considerably, depending upon whether the battery is being charged or discharged and it will also vary with the rate of charge or discharge. The voltage as given will be obtained unless the battery is in a badly discharged condition, while the battery is undergoing a light discharge as when delivering the full lamp load. Under severe starting conditions the voltage may only be three-quarters of that given while the starting current is flowing. Should this not cover what you desire more complete diagram can be secured through the Rostrum department.

2—They probably would in most instances.

ACCESSORIES

Bo-Hart Switch Lock

A SWITCH lock capable of being fitted to a switch plate is just being put on the market. The device is shown in the accompanying illustration attached to a Delco switch faceplate. The lock is comprised of a three-tumble Yale barrel provided with a small gear transmission to interconnect the Yale barrel with the regular locking bar of the switch, and when the lock is applied the Yale barrel and the locking bar of the switch are so interrelated that it is impossible to shift one without shifting both, thus preventing the throwing of the locking bar of the switch through any other means than by the use of the Yale key. These locks are applied to the switchplate at a cost of $4 each retail.—Bo-Hart Auto & Machine Co., Lancaster, N. Y.

Bo-Hart switch lock as fitted to Delco switch faceplate

Featherweight Pistons for Fords

These pistons are of aluminum alloy and are designed to meet the demand for durable light-weight pistons for the Ford engine. Each piston weighs but 1 lb., this feature of the installation tending to reduce vibration and to decrease the wear on the engine parts. Pistons are made in four sizes: the standard, 0.0025 oversize; 0.031 and 0.033 oversize for rebored cylinders. Price, $15 per set, including pins and rings. Featherweight Piston Co., 11 Guyman Way, Pittsburgh, Pa.

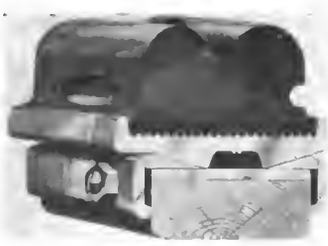
Featherweight aluminum alloy piston for Ford cars. These pistons are made in four sizes

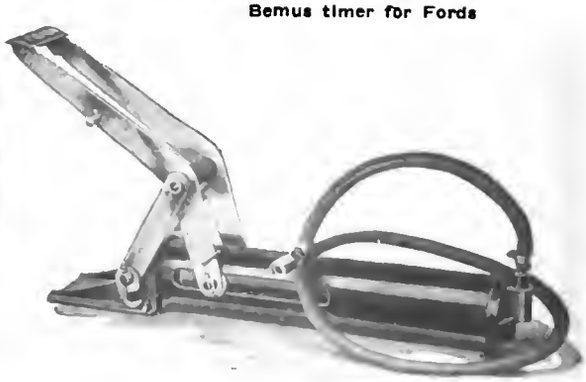
Goodyear Fire Truck Tire

The Goodyear new hand-attachable cushion fire truck tire supersedes the company's cushion demountable type largely used in commercial and fire service. This tire is designed for motor truck and fire apparatus use also, but is stated by the Goodyear company to be tougher, more resilient and able to resist road punishment better than the previous design. The tread is illustrated herewith in section and as a complete unit.—Goodyear Tire and Rubber Co., Akron, Ohio.

Twombly Foot Pump

This pump, as the name signifies, is operated by the foot and the simple leverage action employed multiplies the air pressure delivered to the tire, while at the same time minimizing the effort required on the part of the operator. The manufacturer states that a 34 by 4-in. tire can be inflated to 80-lb. pressure without causing even slight fatigue, due to the fact that no bending of the body is required, the easy action of the pump and the frequent and powerful impulses. A special attachment is provided which locks the pump connection to the tire valve so positively that leakage in pumping is eliminated and the connection is not broken by high air pressure. The pump is 17 by 3-in. over all and is easily packed in the tool box. It contains no parts which will become broken easily under hard service. Price, $4.50.—Schlesinger-Redburn Corp., 1834 Broadway, New York City.





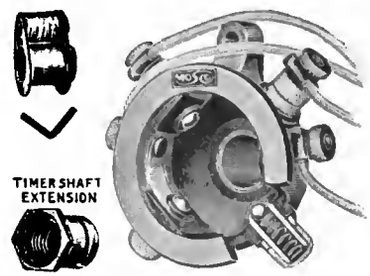
Above—The new Goodyear hand-attachable cushion tire designed for use on automobile fire trucks. Right — Twombly tire pump which is operated by the foot

Ft. Wayne Battery Charger

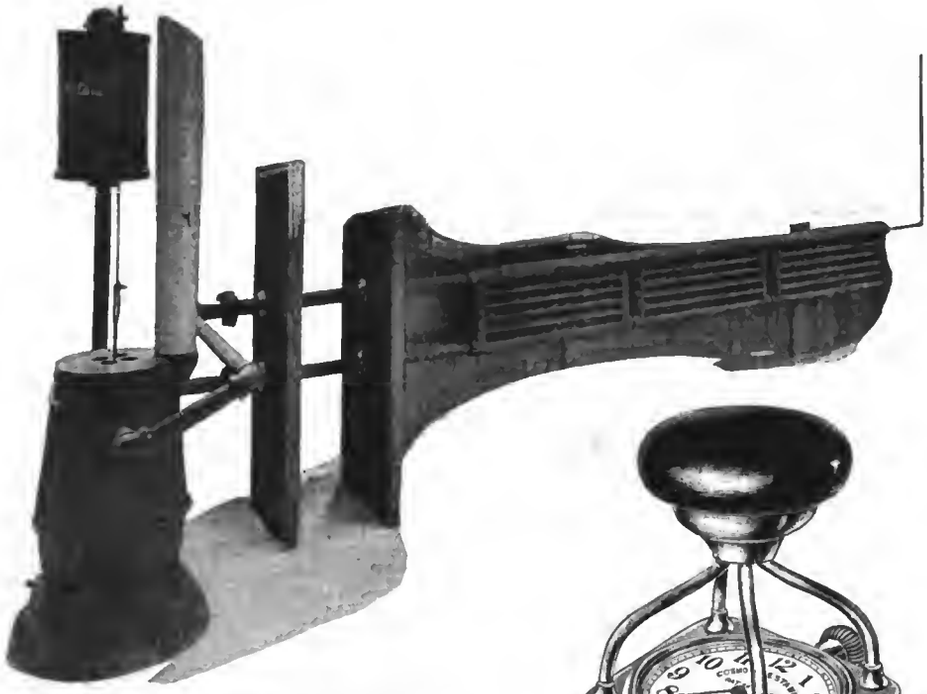
This outfit consists of a motor generator designed to deliver current at 12, 18 and 24 volts and operating from 110 or 220 volts, 60-cycle, alternating current or direct current line. The switchboard panel is mounted on the machine and carries on it the ammeter and voltmeter. Lamp boards are used for resistance. There is a snap switch on the switchboard in the line circuit for the purpose of starting and stopping, the snap switch for opening and closing the charging circuit, a voltmeter for reading the voltage delivered to the generator, an ammeter for reading the charging current, and a field rheostat for raising or lowering the voltage of the generator. The rheostat provided on the switchboard has sufficient capacity to reduce the voltage to 6. The outfits are supplied in 175 and 250 watts capacity.—Ft. Wayne Electric Wks. of the General Electric Co., Fort Wayne, Ind.

Bemus Timer for Fords

In this device contact is made by a hardened steel brush engaging steel balls, the brush and balls turning each time so that new surfaces are continually in contact. Little oil is required, as friction between the balls and the roller is mini-



Bemus timer for Fords



The Wasco private garage heating system can be supplied for one to six-car garages. The heater burns either hard or soft coal of chestnut or pea size, and is fitted with an automatic regulator

mized. The roller is long enough to permit each ball to have a path, lengthening the life of the parts. The shell is made from one piece of an insulating material designed to be strong and impervious to oil and grease. The timer sells for $2.50.—Motor Specialties Co., Waltham, Mass.

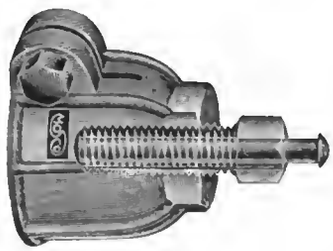
Wasco Garage Heater

The Wasco is a hot-water heating system for private garages. It is equipped with an automatic regulator that is said to give an even heat under varying climatic conditions. The complete outfit consists of a cast iron hot-water heater, one-piece radiator and hot-water cylinder and piping cut to fit. The heater burns either hard or soft coal of pea, chestnut or stove size. Heaters are built for garages housing from one to six cars, the small single radiator system being suited to the 10 by 12 ft. garage. Prices, $35 to $75, depending on the size of the garage. —W. A. Schleit Mfg. Co., Inc., Syracuse, N. Y.

Cosmo Time Stamp

Stamps the time card with the time at the beginning and end of the job, giving the elapsed time accurately. A small metal case holds the watch and carries the stamp indicating the day, hour and minute. Four different models are made, model A having a twelve-hour dial, stem winding and setting. The model AA is the same, except that it has key wind. Model B has a twenty-four hour dial, as has the model BB, the former being stem wind and the latter key wind. This

The Cosmo time stamp is convenient to use, promotes efficiency and protects both the owner and the repairshop man

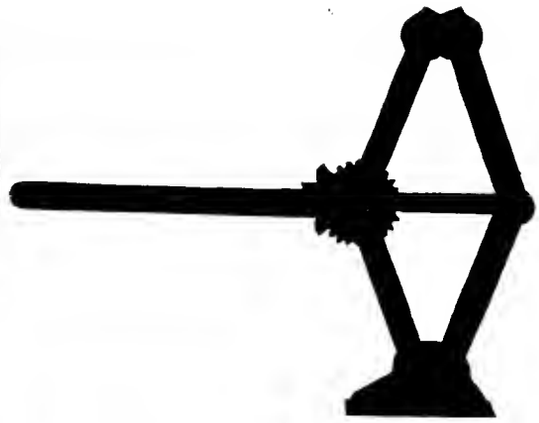


Wheel puller for Ford

time system promotes efficiency, and furnishes the repairman with evidence that cannot be disputed. Price, $7, plain dial. —A. D. Joslin Co., 221 W. Erie Street, Chicago, Ill.

Hi-Lo-Jack

By the use of the toggle joint principle this jack enables the operator to lift a heavy weight with minimum exertion. As shown in the illustration, the upper joints of the toggle are fastened to the top of the jack and the lower joints to the base. The horizontal screw connects the two other joints and applies the leverage which raises or lowers the jack. The side pressure is taken by a ball thrust which eliminates friction and makes lifting easier. When closed the jack is 5 in. high and will lift the load



Hi-Lo-Jack extended

Hi-Lo-Jack in closed pose

to 17 in., the lifting power increasing with the height. A graduated scale shows tons in inches that can be lifted with safety.—Hi-Lo-Jack Co., 140 Green Street, Worcester, Mass.

Wheel Puller for Fords

A loose plunger extending through the center of the screw enables this device to loosen a wheel which is frozen to the axle. The hub cap is removed, the puller screwed on and the set screw tightened. A sharp blow with a hammer on the end of the plunger starts the wheel. Pullers of the same type are made for Overland, Buick, Maxwell, Saxon and Chevrolet cars. The Ford model sells for $1.—Motor Specialties Co., Waltham, Mass.

Wausau Abrasives

Flint paper, emery paper, garnet paper and Wausite are made in various degrees of fineness to suit different work. A handy product is the Wausau waste-proof strip, which consists of a 50-yd. ribbon of emery cloth wound on a spool so that it may be placed conveniently above the bench.—Wausau Abrasives Co., Wausau, Wis.

Resistoil Air Hose

This compression air hose has special oil resisting qualities. The walls are made up similar to the common five-ply hose, which it resembles in outward appearance. The interior of the hose is lined with a special compound that is said to have oil resisting properties, and to resist the action of any oil or oil fumes that may be in the air. Prices, 3/16 in. inside diameter, 16 cents per ft.; ¼ in. inside diameter, 18 cents per ft.; ⅜ in. inside diameter, 27 cents per ft.—Brunner Mfg. Co., Utica, N. Y.

Overdoing Accessories

THE past few years have seen the automobile accessory field extended to an enormous degree and the signs indicate that the limit of what may be called for as stock equipment has been reached. As an example, one prominent Detroit firm has been asked by some of its dealers to supply electric motors on its closed cars whose sole mission in life shall be to open and close the windows on the pressure of a button. Accessories of this sort have no useful purpose. They are merely toys and rank with the big dolls which some fashionable ladies have carried in their arms at the shore resorts this summer. The production of such things is perfectly legitimate, but no manufacturer with a legitimate claim to a place in the industry would seek business on the strength of such accessories.

Small Spark Plugs

IT has become obvious that the S. A. E. will very shortly be compelled to standardize a spark plug of smaller size than the present standard because the larger plug will not stand up in aviation engines or other engines with a very high mean effective pressure and correspondingly high internal temperatures. Makers of aviation engines are unanimously in favor of the metric size of plug and at the other end of the engine scale it is being found that the small plug operates better in tractor engines burning kerosene. On racing engines the small plug is essential and for very high duty touring car motors the small plug has a longer life than the S. A. E. standard plug.

Since engine pressures, speeds and temperatures are generally on the increase, it seems probable that the small plug will become desirable for a wider field than that provided by the aeroplane and tractor requirements, so there is little doubt that the society will have to standardize a small plug in addition to the existing standard. If this is done it is to be hoped the metric plug be chosen and not a plug of similar size with an inch thread, because the metric plug is in universal use in many other countries. Most of the cars exported to British colonies and to South America by several leading manufacturers are supplied with metric plugs.

Adding a small standard would possibly lead to the gradual abandonment of the large plug now standard, but it will be a long time before a complete change takes place, if indeed it ever does. However, so many spark plug makers are now producing metric plugs for export that there should be no difficulty in supplying a sufficiency of the small type to meet any domestic demand that may arise.

The Ford Race

WHY did 10,000 people go to see the Ford race in Chicago? There is a lesson beneath the surface in the interest taken in this event, a lesson that may possibly be applied to all racing and not only to those where a single factory is represented. What is the psychology behind the enthusiasm of these spectators? Certainly not the speed, for even though this was high, it did not approach that of the classics at which the enthusiasm of the spectators has not increased in ratio with the speed made.

There was a human interest feature present that has been lacking in some of the major events which have not been proportionately greater in attendance when the thousands of dollars spent on advertising is taken into account, and the caliber of the drivers is considered. Any man with $400 can buy a Ford. They are on the open market and not beyond the pale of possibility for the ordinary individual. Any man is naturally interested in the performance of a machine which is like one he owns or one he could own if he desired.

Here is a contest for cars that a man can buy. Even if they were made over, and tuned up, the foundation started from a car that is available to the ordinary citizen. In other words, a *stock* car, one produced by a well-known factory. This is the point which puts the interest into the race for the average motorist. If our classics to-day carried the names of our well-known factories in the entry lists, there would be a wonderful revival of interest.

Races as they stand now have not got the personal interest. Talk about Fords and you talk straight to every motorist. Talk about Peugeots and Sunbeams and you do not hit him nearly as hard.

U. S. A. Cars Most Popular in British South Africa

European-Built Cars Not Available and American Machines Win Favor By Performance on Rough Roads and Because of Low Prices

NEW YORK CITY, Sept. 8—One of the largest and best known dealers in British South Africa is at present in this country making arrangements for distributing U. S. A. accessories throughout that country, as well as traveling over the majority of the United States. This person is Wm. Campbell of Johannesburg, who is the Maxwell dealer in that city and also represents Prest-O-Lite batteries, Simms magnetoes and other U. S. A. products.

Mr. Campbell, a Scotchman by birth, has the reputation of being one of the shrewdest dealers in that country. In the last 9 months he distributed over 600 Maxwell cars, and will exceed that figure very materially this year. He sold 50 to the government for war purposes in German East Africa.

According to Mr. Campbell, the U. S. A. cars are selling in greater quantities than any other cars in British South Africa. This is partly due to the fact that European cars are not available, and also to the fact that our cars are low-priced and well suited for the rough roads of British South Africa.

Farmers Good Buyers

The majority of U. S. A. cars are sold to farmers who reckon their land in morgens instead of acres. A morgen equals 2.5 acres and many of the farmers own 10,000 or more morgens. South Africa thus resembles Argentina in that it is not a land of small farmers as in our Mississippi River valley, this being due to great areas and sparse population.

At present Ford is the biggest seller in British South Africa, with Maxwell a close second. Other large sellers are Overland, Buick, Studebaker, Hupmobile, Chevrolet, Dodge and Cadillac. Cadillac has been the largest seller of U. S. A. high-priced cars. From four to six times as many of these cars have been sold since the war as prior to it, a condition largely due to the inability to secure European cars.

Roads Are Lacking

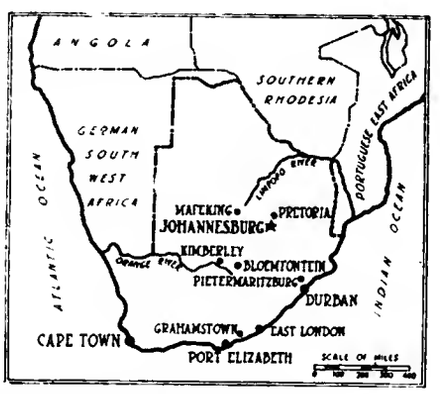
British South Africa is a country without roads. In this respect it is worse than Australia, worse than Argentina and practically as bad as Brazil. In Johannesburg, a city of 200,000 whites, there are good roads no further than 5 miles out in the country. In British South Africa the population of cities is generally estimated on the number of whites, as they represent the potential purchasing capacity of the city. In addition to these whites there are 500,000 colored people in the Greater Johannesburg area, giving a total population of 750,000.

Outside of the cities the roads are mere trails, two ruts, and often between these the ground is often 6 to 8 in. high, which demands cars of good clearance, 10 in. being best suited for the work. In many places the cars are driven directly across the veldt or plains. Recently Mr. Campbell made a trip of 1826 miles, driving from Cape Town at the south end of the continent to Johannesburg. The distance between these two towns is 1000 miles by direct route. Generally speaking there are few if any bridges, making fording essential.

Pass to the Left

According to the rules of the road in British South Africa you pass to the left, instead of to the right, as we do. This calls for cars with steering wheel on the right hand side, the same as required in South America, Australia and England.

The five-passenger touring car is the big seller. The sale in roadsters is perhaps 10 per cent that of touring cars. There is a very limited demand for coupés, but practically none for sedans or cabriolets.



British South Africa, showing the larger population centers—Johannesburg is destined to be the great automobile and supplies distributing point

Only 15,000 Cars

Mr. Campbell can place no estimate on the total number of cars in British South Africa. The figure is somewhere near 15,000. The country has a total population of 1,250,000, or a little less than Uruguay in South America.

At present there are approximately the following number of automobiles in the following cities:

Johannesburg	6,000
Cape Town	4,000
Durban	500
Bloomfontain	500
Port Elizabeth	400
East London	300
Kimberly	200

The high price of gasoline is a big factor in South Africa, where the imperial gallon retails at 88 cents in Johannesburg, and but a little lower at Cape Town and other coast cities. The imperial gallon is approximately one-sixth larger than the gallon used in the U. S. A. With gasoline at this price it is essential to have cars that will show good performances, and 30 to 35 miles per gallon is necessary. Gasoline is handled in British Africa much the same as in England, namely in crates of two 5-gal. cans each. Handling it by bulk has not yet taken hold.

Accessory Market Good

The possibilities for U. S. A. accessory manufacturers are good in British South Africa. Already many of our leading accessories are handled there. Some of them are sold through New York exporting houses, and others are handled through large distributors who deal direct with the U. S. A. manufacturers. There is a big market for pumps of all kinds, head lights, shock absorbers, searchlights, dash lights, and in general all car fitments, that is, little devices that really improve the value of the car to the owner.

Unfortunately U. S. A. accessory trade in British South Africa has suffered because our accessory makers have not been dealing direct with the big distributors in that market. As a result some lines of goods that should be in much demand there are in ill favor. This is not due to the goods themselves but

Studebaker Plans Expansion

Will Expend $1,500,000 on Factories in Detroit and South Bend

DETROIT, MICH., Sept. 8—Plant expansion to cost $1,500,000 has been announced by the Studebaker Corp., this applying to the factories here and at South Bend, Ind. When these extensive undertakings are completed the capacity of the combined factories will make it possible for the corporation to exceed a $100,000,000 annual turnover, according to A. R. Erskine, president.

Already contracts have been let for the construction of a large modern foundry and an extensive machine shop to be erected on part of the land now occupied for lumber storage at the South Bend factory. The foundry will be 1100 ft. long and 150 ft. wide, with four cupolas and 250 tons daily melting capacity, and it is to be completed by July 1 next. The machine shop is to be about 900 ft. long by 300 ft. in width, and will double present machine shop facilities at South Bend.

Detroit contracts are now being let for the construction of a one-story building with about 25,000 sq. ft. of floorspace, adjoining plant No. 3, which is located on the west side of the city. It will be devoted to final assembly work. Another floor, measuring 50 by 300 ft., is to be built on one of the three-story buildings now used as a warehouse for materials. This latter addition will enable the still greater stocking up of materials in advance of immediate needs. Other extensive additions to the Detroit plants are to be made, but details of these are not given out at this time.

Automobile Gain the Cause

It is pointed out that these plant extensions of the corporation are made necessary because of the development and growth of the Studebaker automobile business during the past 5 years. In 1911 the sales of the concern amounted to $28,487,000 and included 22,555 automobiles. In 1915 the sales had increased to $56,539,000, during which year 46,850 automobiles were sold. It is predicted by President Erskine that in the current year Studebaker sales will approximate $70,000,000, and the number of cars 75,000. During the 5 years under review, the real estate and plant investment account of the corporation has increased from $10,554,000 to $12,400,000, or nearly $2,000,000, so it appears the corporation was able to increase the production capacity of the factories without increasing the investment in proportion to the increase in business.

At South Bend alone the new buildings will mean the adding of 1000 men to the working force, and at Detroit the number will be swelled to 7000.

Few persons realize the extent of the automobile operations now carried on at the South Bend factories, the public generally regarding this part of the big corporation as being devoted to carriage, wagon and harness business entirely. Prior to 1912 the South Bend works were devoted exclusively to the manufacture of horse-drawn vehicles and harness, but in the latter part of that year the making of automobile springs and some castings was commenced. In 1914 the automobile body factory was installed, and last year some light stampings were first manufactured in South Bend. Now the plants in that city are manufacturing automobile parts for the Detroit plants of the value of over $10,000,000 per year, and the average number of employees has increased from 2701 in 1912 to 5023 at the present time, due to the use on motor vehicle work of available facilities at South Bend.

H. A. L. Plans Greater Business

CLEVELAND, OHIO, Sept. 11—Following the elevation of A. Ward Foote to the presidency of the H. A. Lozier Co., plans have been made for an increased production. The company was formed last Winter, made first deliveries of the H. A. L. in May and plans to have delivered 1000 by the end of the present year. Merchandise orders have been placed for material for 2000 cars for the 1917 calendar year. A change in the corporate name is contemplated. The company as now constituted includes:

President, A. Ward Foote, president of the Foote-Burt Co., Cleveland, machinery maker; vice-president, Charles C. Homan, former Overland purchasing agent; secretary, Frank H. Ginn, attorney; treasurer, E. G. Tillotson, of Tillotson & Walcott, bankers; the directors are the officers and the following: George E. Randles, vice-president, Foote-Burt Co.; Amons N. Baron general manager, National Carbon Co.; Morris Towson, president, Elwell-Parker Co., machinery maker, and also director in Anderson Electric Car Co. George H. Bowler is general sales manager. Jay Lee Cross has gone with the company as manager of the advertising department. Practically all of the stock is owned in Cleveland. The capitialization now is $700,000.

Harvey Adds Heat Treating Building

RACINE, WIS., Sept. 7—The Harvey Spring & Forging Co., this city, has broken ground for a new fireproof building, 100 by 200 ft., of steel construction, to be used exclusively for forming and heat treating automobile springs.

Italian Tire Plants Are Busy

Conditions Little Affected by War—American Cars Not in Demand

NEW YORK CITY, Sept. 8—The tire industry in Italy is at present in a very prosperous condition. G. A. Pirelli, son of the owner of the Pirelli Tire Co., which employs 10,000 in its various factories, is visiting this country to make purchases of machinery and other supplies for his father's plants in Bicocca, Italy; Barcelona, Spain, and Southampton, England. This company is the largest producer of tires in Italy and has been in the tire business 15 years. Over 1500 pneumatic tires and tubes are turned out daily and truck tires number about 800 daily.

As there are only two other large tire concerns in Italy, namely, Michelin and Tedeschi, the tire production is one of the most important branches of the automobile industry there, as it supplies nearly 130,000 cars and has little competition from other countries.

War Orders a Factor

The Italian tire, automobile and truck firms are busy at the present time with war orders, which constitute most of the business. Industrial conditions have been little hampered by the war and the factories have kept busy supplying the government and domestic wants. New plants are being built to take care of this large demand.

Mr. Pirelli states that there is little demand in Italy for our automobiles, especially the low-priced cars. The purchasing of cars is by the wealthy class, who want expensive bodies and high-class finish, regardless of the price. The middle and poorer classes who cannot afford cars are satisfied to ride in the street cars, or if a long trip is made, to ride in a taxicab, which may be had at a very reasonable price.

Self-starters and electric gear shifters are not in demand in Italy. This is explained by the fact that very few cars are driven by the owners and as a consequence such labor-saving equipment is not considered necessary.

Keller Tool Moves to Grand Haven

FOND DU LAC, WIS., Sept. 9—The Keller Pneumatic Tool Co., Fond du Lac, has decided to move its works and general offices to Grand Haven, Mich., and will maintain the present plant as a branch. The Chamber of Commerce of Grand Haven has provided a free site and local capital will become interested to the extent of $60,000. The first of a new group of shops will be undertaken at once. It will be 90 by 300 ft.

S.A.E. Memberships for Aero Men

Dues Cancelled if A. S. Members Join S.A.E. Within Next 90 Days

NEW YORK CITY, Sept. 12—At today's meeting of the council of the Society of Automobile Engineers it was decided to admit membership of the Aeronautical Society into the S. A. E. without payment of annual dues, providing these memberships are taken out within a period of 90 days. This action is a natural step in the development of the Society of Automotive Engineers, which will be the new name of the S. A. E. after the first of the year. The aeronautical engineers were the first to express a desire for co-operation with the S. A. E. under its new name, and already upward of thirty of their leading engineers have applied for membership. It is anticipated that other engineering societies will amalgamate in the Societiy of Automotive Engineers. Already the National Gas Engine Association has expressed interest in the possibilities of one large engineering society such as the Socety of Automotive Engineers. Overtures have been under way with the Society of Tractor Engineers and interest has been shown by the marine and motorboat engineers. It would be greatly for the benefit of all these societies for them to pursue their work under the one title of Society of Automotive Engineers.

100 Per Cent Financial Gain

The success of the S. A. E. during the present fiscal year, which will end Oct. 1, was well indicated by the treasurer's report, which approximated that the profits for the year would be close to $14,000, or nearly double the profits of the 1915 year. The total asscts at the end of the 1916 fiscal year will approximate $30,000, as compared with slightly over $8,000 at the end of the last fiscal period. During the present year the society has made several investments, one being the purchase of approximately $10,000 worth of bonds, which investment has been handled by the finance committee. The society has other investments in the form of certificates of deposit approximating $19,000. On its various investments it will earn over $1,100 interest this year.

100 New Members

It is rare that so many new members are taken into the society at any one time as was the case at to-day's meeting. A round total of 100 were admitted to membership into the different grades, as follows: Membership, fifty-three; associates, thirty-seven, and junior, eleven. In addition, there was considerable student enrollment. C. W. McKinley, engineer of the Willys-Overland Co., was elected to membership in the council to succeed past President Harry M. Leland.

—

Kettering to Talk on Temperature

DETROIT, MICH., Sept. 9—Motor Temperature Control is the very interesting title of a paper to be presented at the next meeting of the Detroit Section of the Society of Automobile Engineers by C. F. Kettering, vice-president and general manager of the Dayton Engineering Laboratories Co. The meeting is scheduled for Sept. 14, and is to be held in the convention hall of the Pontchartrain Hotel. The society predicts a record-breaking attendance at this first meeting of the new season. Mr. Kettering is eminently qualified to give an authoritative paper on this subject, which is engrossing the engineering fraternity at the present time, and some valuable information will undoubtedly be forthcoming.

—

Pushing Work on Dann Factory

CLEVELAND, OHIO, Sept. 11—Work on the new factory for the Dann Products Co. is progressing and E. G. Dann, general manager, states that the plant will be operating at full capacity by Oct. 1. This company manufacturers the Dann Insert and the new bearing metal Dannite.

The new building adjoins the plant of the Jordan Motor Car Co. and is 150 ft. by 300 ft., including unusual lighting facilities, and every possible convenience for the welfare of the workers. The company is moving to Cleveland from Chicago and has recently raised its capitalization from $60,000 to $600,000.

—

Firestone Making 12,000 Tires a Day

AKRON, OHIO, Sept. 11 — Statements published in connection with the announcement of the contemplated stock dividend of the Firestone Tire & Rubber Co. show that the plant is now turning out 12,000 tires a day.

Last year the output increased 78 per cent and 50 per cent more dealers were added so that production has not yet kept pace with sales.

The Firestone Tire & Rubber Co. is now building one of the best equipped club houses in the country for its employees. The first and second floors will contain a restaurant, while the basement will have a swimming pool, shower baths and bowling alleys. The third floor will be taken up with an auditorium and club rooms.

This company has also purchased several hundred acres of land and contemplates the establishment of a Firestone Bank to help its employees to finance their own home building.

Independents Meet S. O. Reduction

Texas Co. and Others Cut Prices 1 Cent in East and West

CHICAGO, ILL., Sept. 9—The Texas Co. and other independent oil concerns met the Standard Oil Co. of Indiana's 1-cent reduction in gasoline throughout the West by making Chicago tank wagon basis 16½ cents a gal.

The Standard Oil Co. in Kansas City, Mo., has reduced gasoline 1 cent a gal., to 15.8 cents tank wagon basis, and independents have cut prices 1 cent, to 16.8 cents tank wagon basis to meet the new market conditions.

The price of gasoline was cut another cent in Detroit, Sept. 7, by the Standard Oil Co., being obtainable at any of the Standard's forty filling stations in the city at 17 cents a gal. So far the independents have not met the reduction, some demanding 18 cents and others getting as high as 19 and 20 cents, the latter price being asked by individual garages in some instances.

The Texas Co. has met the 1-cent reduction of the Standard Oil Co. in the East, covering New York State, Connecticut and New Jersey. Texas gasoline in New York and Connecticut is quoting at 22 cents tank wagon basis and in New Jersey at 20 cents. The Standard Oil Co. brought its price down to 22 cents on Sept. 7.

Lower in West

Gasoline prices have been reduced 1 cent a gal., tank wagon basis, in Colorado, Montana, Wyoming and New Mexico. Current prices are: Colorado, 21 cents minimum to 25 cents maximum; Montana, 23 cents minimum to 24½ cents maximum; New Mexico, 20 cents minimum to 24½ cents maximum; and Wyoming, 1912 minimum to 23½ maximum.

—

Irwin Leaves Adams Truck to Join Allen M. C. Co.

FINDLAY, OHIO, Sept. 7—Murray Irwin has resigned his position as general manager of the Adams Foundry, Machine & Truck Co., and joined the Allen Motor Car Co., Fostoria. George Carter of Jackson, Mich., has been placed at the head of the Adams plant.

—

Standard Traffic Code Distributed

NEW YORK CITY, Sept. 12—The Standard Code of Traffic Regulations which has been drawn up tentatively by the Street Traffic Committee of the Safety First Federation of America has been

submitted to municipalities for adoption. The code represents the work of a year and a half on the part of the committee with consultations and assistance from traffic experts throughout the United States and Canada. It is comprehensive, covering all the possibilities of traffic regulation down to its most minute detail. The headlight glare regulation is one that has been approved by the Society of Automobile Engineers and provides for an illumination up to 150 ft. in front of the car wherever the highway is not sufficiently lit by street lamps and also that no portion of the beam of reflected light when measured 75 ft. or more ahead of the lamp shall rise above 42 in. from the level surface on which the vehicle stands. The S. A. E. standard license plate is also indorsed as well as a standard gearshifting gate.

—

Lansing Foundry Elects Officers

LANSING, MICH., Sept. 6—At the annual meeting of the directors and officials of the Lansing Foundry Co., the following officers and directors were re-elected: J. H. Moore, president; Ray Potter, vice-president; Mark C. Knight, treasurer, and S. P. Spaulding, secretary. These officers and W. H. Newbrough, E. W. Goodnow and E. W. Harper make up the board of directors.

The foundry is being operated to its full capacity and has so many orders on its books that it has refused to take on more business. It is likely that the plant will be enlarged within the next year.

—

Marathon Tire Convention Starts

CUYAHOGA FALLS, OHIO, Sept. 8—The Marathon Tire & Rubber Co., this city, will hold its annual sales convention at its factory during the week commencing Sept. 11, under the direction of H. H. Replogle, sales manager.

6501 Vehicles Exported in July

—

5258 Passenger Cars and 1243 Trucks and Parts Worth $1,630,111

WASHINGTON, D. C., Sept. 9—While there has been a decided drop in the demand for commercial cars, due to the curtailing of orders from the warring nations in Europe, exports of passenger cars show a big increase during July and the 7 months ended July as compared with the same periods of last year. Statistics of automobile shipments during those periods have just been made public by the Department of Commerce, and show that during July last 1243 commercial cars, valued at $3,062,670, and 5258 passenger cars, valued at $3,663,563, were exported, together with parts, not including engines and tires, to the value of $1,630,111. During the 7 months' period of this year the exports were divided as follows: Commercial cars, 11,373, valued at $30,725,682; passenger cars, 38,407, valued at $25,897,743; parts, not including engines and tires, $13,175,266.

During July a year ago the exports were 2469 commercial cars, valued at $6,803,001, and 4118 passenger cars, valued at $3,835,347. The value of the exports of parts, not including engines and tires, was $1,663,997. For the 7 months of last year the exports were 13,428 commercial cars, valued at $37,499,768, and 22,897 passenger cars, valued at $20,454,354, while the value of the parts exported, exclusive of engines and tires, was $7,343,119.

France Leads in July

France held first place in the value of the imports of American cars during July last, 538 cars, valued at $1,354,968, being shipped there during that month, while during the same month of last year the number was 615 and the value $1,260,693. During the 7 months' period these exports increased from 4268 cars, valued at $10,547,826, in 1915 to 5655 cars, valued at $13,857,692, in 1916.

Three hundred and thirty-four cars, valued at $605,799, were shipped to the United Kingdom during July last, while during the 7 months of this year the number exported was 6281 and the value $9,857,900. In July a year ago the number of cars exported was 2619 and the value $3,836,296, while during the 7 months of that year the number was 14,494 and the value $21,998,112.

Russia came to the front in July last with orders for 298 cars, valued at $790,443, while during the 7 months' period the number exported there was 1393, valued at $3,991,594. Russia did not figure in the export returns in 1915.

Denmark's importation of American cars in July last numbered eighty-six cars, valued at $64,605, while during the 7 months' period the number was 596 and the value $434,239. That country was not listed separately in the export returns for 1915.

Canada Makes Big Gain

Our exports of cars to Canada show a decided increase. During July last 690 machines, valued at $605,897, were exported there, as against 643 cars, valued at $428,348, shipped in July a year ago, while during the 7 months' period the exports rose from 3961 cars, valued at $3,192,526, in 1915 to 8616 cars, valued at $6,027,295, in 1916.

South American countries are taking kindly to American-built cars. In July a year ago there were 315 cars, valued at $157,964, exported to all the South

G. M. C. Feature Securities

Reaches New High Record, Setting Mark for New York Stock Exchange

NEW YORK CITY, Sept. 13—General Motors common sold yesterday at $642 a share. This is not only a new mark for the stock itself, but actually sets a high record for the New York Stock Exchange. In the panic of 1901 Northern Pacific sold at $1,000, but that was a quotation forced by a corner.

During the last week securities quotations were slightly off. Firestone Tire & Rubber common which had increased 25 points the week previous fell off this week 30 points. Other tire stocks, however, were stronger, Goodyear increasing by 7 and Kelly-Springfield by 2⅝. In the main all the motor stocks were quite strong. Packard was up 5 and Paige-Detroit up 7.

Dunlap Leaves Hupp

DETROIT, MICH., Sept. 8—C. H. Dunlap, export manager of the Hupp Motor Car Corp., has resigned to become interested in another enterprise. He has headed the Hupp export business for several years, and is familiar with nearly all of the world's shipping points.

Truck Makers Draw Together

NEW YORK CITY, Sept. 11—The Cook Attachment Patents, Inc., has been formed here with $10,000 capital to bring into closer relationship manufacturers of attachments for converting passenger cars into commercial vehicles. Albert E. Cook, whose patent No. 1,180,475 on such devices now is in process of litigation in Chicago, heads the company, the other officers elected so far being, president and treasurer, Mark W. Norman, a New York lawyer, and secretary, B. H. Barber. The organization will issue manufacturing licenses under the Cook patents, the Redden Motor Truck Co. at present being the sole licensee.

Paige May Increase Capital by $1,500,000

DETROIT, Sept. 11—The Paige-Detroit Motor Car Co. will hold a special stockholders' meeting on Sept. 19, at which action will be taken upon a recommendation of the directors that the capitalization of the company be increased from $2,000,000 to $3,500,000, through the issuance of $1,500,000 in preferred stock. On Sept. 2, the Paige company increased the capitalization by the declaration of a 50 per cent stock dividend to holders of record Sept. 9, and the recommended issuance of preferred stock is another step in the company's financing.

S. S. E. Co. to Build

PHILADELPHIA, PA., Sept. 8—The S. S. E. Co., Philadelphia, has awarded the contract for the first of a series of buildings to be erected in this city. The plant is one story of brick and concrete and measurers 360 by 90 ft. The company will make a $5,000 chassis.

Atlas Forge Declares 100% Dividend

Second Melon Within 10 Days Due to Business Being Twice as Good as in 1915

LANSING, MICH., Sept. 6—For the second time within less than 10 days the Atlas Drop Forge Co. has declared a dividend. The first one was a cash dividend of 20 per cent, while the second one, declared this week, is a 100 per cent stock dividend. The business of the company is said to be more than 100 per cent better now than it was 1 year ago. Two shifts are working at the plant.

Armstrong Tire Plant to Operate

NEWARK, N. J., Sept. 7—The Armstrong Rubber Co., this city, is equipping its factory in this city for the manufacture of the Armstrong red inner tubes equipped with the Kahn valve.

Dividends Declared

Directors of the Chandler Motor Car Co. last week declared the regular quarterly dividend of 2 per cent and an extra 1 per cent. This compares with an extra three months ago of ½ of 1 per cent.

Electric Storage Battery Co., quarterly of 1 per cent on preferred and common, payable Oct. 2, to holders of record Sept. 18.

Allis-Chalmers Mfg. Co., quarterly of 1½ per cent on preferred, payable Oct. 16, to holders of record Sept. 30.

Fosters Trade with Argentina

American Commercial Club of Buenos Aires To Give Information

BUENOS AIRES, Aug. 6.—Automobile concerns doing business in Argentina can be greatly assisted by the American Commercial Club, an organization of U.S.A. business men in this city. This commercial club has as its object the improving of trade relations with the United States of America. Recently this club has associated itself with the United States Chamber of Commerce, Washington, D. C., and has established itself as a clearing house for information of U.S.A. manufactures of all kinds.

In addition to being prepared to give any U.S.A. manufacturers information regarding any conditions in Argentina, the American Commercial Club is playing the rôle of an arbitration board for the purpose of adjusting complaints made by Argentine merchants against firms in the United States. These complaints are often due to delayed shipments, goods not corresponding with samples, etc. In a word, this club is endeavoring to facilitate and improve the commerce between the two countries, all of which is highly necessary if U.S.A. is to secure that control of the Argentine trade which it should.

In carrying on this work the American Commercial Club is put to considerable expense, the cost being approximately $10,000 a year. The business merchants here, who are members of the club, are willing to give their time and some of their money for the purpose of carrying on this work, but cannot meet the entire financial responsibility. U.S.A. automobile manufacturers who are now intensely interested in Argentine can assist by subscriptions of $25 or more per year. It is possible to obtain memberships in the chamber for a nominal sum, and thus get advantage of all information collected by it. The officers of the club are all U.S.A. people, and hold responsible positions in the city. They all hold power of attorney for their respective companies and represent the best business blood of the U.S.A. in Argentina.

The officers and directors are: President, J. L. Wheatley; vice-president, Louis C. Young; secretary, Alfred Eichler; treasurer, A. T. Brooks; and governors H. E. Finney, W. J. Pilant, and S. D. Allchin. Mr. Finney is manager of the Armour meat packing industry, which has the most modern slaughter-house in the world; and Mr. Pilant is manager of the International Harvester interests for Argentina, Chile, Brazil, Uruguay and other parts of South America.

The club is located in the Plaza Hotel, Buenos Aires.

Vail Tractor Uses Gasoline or Kerosene

HAMILTON, OHIO, Sept. 8 — The Vail-Rentschler Tractor Co., Hamilton, now being organized with an authorized capital of $100,000 to build and market the medium weight Vail tractor, which will operate with either gasoline or kerosene. The incorporators and stockhoders are: G. A. Rentschler, chairman, of the Hooven, Ownes, Rentschler Co.; Col. C. B. Wing of Cincinnati; J. A. Vail, formerly chairman of the board of directors of the Maxwell Motor Co.; G. S. Rentschler, vice-president of the Hamilton Foundry and Machine Co., and C. Vail of Chicago.

A plant is now being equipped opposite the Butler County Fair Grounds in Hamilton.

Materials Market Steady

NEW YORK CITY, Sept. 13—No important changes were recorded in the materials market during the past week. Aluminum held its 60 cents a pound level, due to the great demand among automobile manufacturers. Fine up-river Para rubber advanced 2½ cents per pound. Tin, which has been falling off in price for the last 2 weeks, has dropped another 75 cents per 100 lb., being down to $38 even at the market close on Monday. The copper prices, which have been 28 cents for some time, are steady.

Hupp Car Averages 18.96 M. P. G.

301 Miles, Albany to Buffalo, in Test—1204 M. P. G. of Oil Used

COLUMBUS, OHIO, Sept. 12—The Hupmobile car, which is making a capital-to-capital tour throughout the United States, arrived in Columbus, its twelfth State capital, this evening from Cleveland. After pausing at the capitol building and visiting the local dealers, the party left for Xenia on the way to Frankfort, Ky. The car is going by way of Cincinnati, and after leaving Frankfort will go to Indianapolis.

On the way from Albany to Buffalo an economy test under the sanction of the American Automobile Assn. was made, and on the 301 miles the average fuel consumption was 18.96 miles per gallon. The average mileage per gallon of oil was 1204, and per gallon of water 602. The only work done on the car between Albany and Buffalo was to clean the dirt from the bottom of the spray nozzle. The A. A. A. has guaranteed the stock status of the car which corresponds to catalog dimensions in all respects. In equipment a spotlight is carried and Goodyear all-weather tread tires are used on the front wheels as well as the rear. The amount of gasoline used on the trip was 15 gal. and 7 pt.; oil, 1 qt., and water, 2 qt. An overnight stop was made at Syracuse, which is about midway between Albany and Buffalo. The roads are in excellent condition and the country of a rolling nature.

Gaso-Kerosene Tractor Embodies Many Features

LODI, WIS., Sept. 9—The first models of a new gaso-kerosene tractor manufactured by E. J. McFarland and J. C. Westmont, Lodi, Wis., are now being exhibited at state and county fairs and given demonstrations on northwestern farms. The tractor is an assembled machine, the units being purchased from specialists. The use of a Bennett carbureter makes it possible to use gasoline, kerosene, distillate or motor spirits as fuel. The tractor pulls three 14-in. plows and has belt power for 18-in. silage cutters and 28-in. threshers. A 50-hp. motor also is furnished. The engine is a Waukesha, with Eisemann magneto and Perfex radiator. The builders also use Clark universals, Foote gears, and Hyatt bearings. The axles, frame, wheels and drawbar are provided by the Electric Wheel Co., Quincy, Ill., and the clutch is a Borge & Beck dry disk. The universals are unique, being of the steamship type and new to tractor design.

Astor Cup Will Be 250 Miles

Sept. 30 Event Carries $25,000 in Prizes—To Start at 2.30 P. M.

NEW YORK CITY, Sept. 8—The Astor Cup Race will be held on the 2-mile Sheepshead Bay Speedway here on Saturday, Sept. 30. The race will be for 250 miles instead of 350 as used last year. The shorter distance has been selected to increase the popularity of the event. With 250 miles it will be possible to start the race at 2:30 p. m., thus giving all Saturday afternoon holidayers an opportunity of witnessing the start and the entire race.

The prizes total $25,000, or at the rate of $100 per mile. This is divided as follows:

First prize...	$10,000	Sixth prize....	$1,200
Second prize.	5,000	Seventh prize..	1,000
Third prize...	2,500	Eighth prize...	900
Fourth prize.	1,600	Ninth prize....	800
Fifth prize...	1,300	Tenth prize....	700

For some time there has been some question as to whether this race would be held or not because of certain internal troubles with the track organization. These were all clarified at a meeting yesterday when complete arrangements for the race were perfected.

No list of entries has as yet been compiled, but promises are on hand for fourteen entrants and it is expected that the usual elimination trials will be held previous to the race so as to reduce the field to meet the speedway requirements.

—

U. S. A. Cars Popular in South Africa

(*Continued from page* 455)

to the houses handling them. There are some houses that have rather unsavory reputations in that country and it is certain the sale of products is going to suffer because of such. In South Africa, the same as in Australia and South America, the motor car trade is sufficiently large to warrant our manufacturers dealing direct with the large houses in that country.

Light Car Opportunities

There is a good chance in British South Africa, according to Mr. Campbell, for a U. S. A. light-type car, built on the lines of the English Singer. It should be a two-seater that would sell for $1000 and show 35 miles per gallon of gasoline. Such a car would have to have good lines and be well built.

Owing to the high price of gasoline there is a good demand for electric passenger and commercial vehicles. With gasoline at 88 cents per gallon and electricity at 2 cents per kilowatt, there is good opportunity, particularly in Johannesburg for selling electrics.

At present the commercial vehicle business in Johannesburg is largely confined to fitting delivery bodies on such chassis as Overland, Studebaker, Maxwell, Ford, etc. Much of this has been done in the past year and the market is increasing.

Johannesburg is destined to be the great motor car distributing center for British South Africa. It has by far the largest population and is surrounded by a productive country. The city is located on a plateau 6000 ft. high, 1000 ft. higher than Denver, Col., and has a climate practically the same as Los Angeles. Some of the staples in the surrounding country are corn, cotton, tobacco, oats, other cereals, and fruits.

At present business conditions are very satisfactory. Immediately after the opening of the war there was a shrinkage of general business for a few months, but since then prices have been so good that the country is more prosperous than in times of peace.

—

6501 Cars and Trucks Exported in July

(*Continued from page* 458)

American countries, while during the 7 months' period of that year the number was 1212 and the value $643,718. This year these exports have increased in value to such an extent that the leading countries of South America have been listed separately in the export returns. Argentina's importations of cars in July last amounted to 888 cars, valued at $419,512, while during the 7 months of this year the number was 3653 and the value $1,777,155. The cars shipped to Chile in July last numbered 125 machines, valued at $81,815, while during the 7 months' period the number was 551 and the value $361,433. Brazil's importations numbered fifty-four cars, valued at $43,116, in July and 251 cars, valued at $169,732, during the 7 months' period. The shipments to Venezuela in July amounted to eighty-four cars, valued at $59,872, and during the 7 months to 361 cars, valued at $221,334. Shipments to other South American countries amounted to 146 cars, valued at $85,494, in July and to 567 cars, valued at $335,376, during the 7 months of this year.

Substantial gains are also noted in the export returns to British East Indies, Australia, Asia and other Oceania.

—

Pettit Resigns from Case

RACINE, WIS., Sept. 8—B. M. Pettit, for 3 years advertising manager of the J. I. Case T. M. Co., Racine, Wis., has resigned to accept an executive position with the Curtis Publishing Co., at Philadelphia.

11 Owen-Magnetics on 5-Day Tour

R. M. Owen Host to Over 50 on Trip Through New England Hills

NEW YORK CITY, Sept. 13—Inviting over fifty men to go as his guests on a 5-day tour through the best touring sections of New England, R. M. Owen of this city added a second chapter to his original move started a year ago. These fifty men were carried in eleven Owen-Magnetic cars furnished by Mr. Owen, who took control of the Entz patents 5 years ago and since has been developing and perfecting the Entz system as used in the Owen-Magnetic cars. Mr. Owen paid all the expenses of all his guests.

A year ago Mr. Owen conceived the idea of an invitation tour, inviting those people he wished to demonstrate his car to go along and see the electric-magnetic transmission system operate on the roads, on the hills and under all touring conditions. He went further and gave many of his guests opportunities to drive the cars on the trip. Last year three small trips were staged and they proved so successful that a 5-day tour with eleven cars was successfully carried out this year. The tour ended in this city today and was most successful.

Among the fifty invited guests were several Owen-Magnetic private owners who drove their own cars, several Owen-Magnetic dealers from New York, Philadelphia, Boston and other cities who drove their cars and brought friends along, and also many of the officials of the Baker R. & L. Co., Cleveland, which is manufacturing two models of the Owen-Magnetic cars. The party included Chas. L. F. Wieber, president of the Baker R. & L. organization; J. B. Entz, Sr., inventor of the Owen system; Stephen Bourne of Philadelphia, who is manufacturing a truck using the Owen system, etc. The class and daily press was well represented.

180 Miles a Day

Approximately 180 miles per day were covered on the tour, the itinerary including New York City, through the Berkshires by way of Pittsfield and Greenfield, and thence to the White Mountains by way of Franconia, thence back to Boston and to New York via Springfield and Hartford.

The tour offered two exceptional hill-climbing tests, one over the famous Mohawk trail near North Adams, Mass., over a road built 2 years ago, and one that is looked upon as one of the best climbs in New England. There is 7 miles of climbing with a sharp S turn in the steepest part. The road in many places

is cut into the solid rock in the mountain side.

The other hill-climb was up what is known as 3-mile climb near the Profile House in Franconia, the heart of the White Mountains. This climb is steeper than that over the Mohawk trail, and is over a rather poor road through the wooded mountain. The road rises in a series of very rapid climbs, with several water breaks.

A Severe Test

The hill-climbing ability of the electric transmission received its severest test. The cars demonstrated that the electric-magnetic system possesses superior qualities for this kind of work. The fact that the power is applied continuously when changing from one electric position to another and that there is not a moment when the power of the motor is cut off from the rear wheels proved a real factor in hill-climbing. This continuous power is quite apparent in such severe hill-climbing work. Not only is there the advantage of the continuous power, but the absence of any mental problem in connection with gear shifting. That problem is quite eliminated, for it is as easy to shift from one electrical position to another as to move the throttle lever on the steering wheel.

Mr. Owen has provided in his cars for such severe hill-climbing work a lower gear ratio, which was used by practically all of the drivers. On this lower ratio it was possible to make the ascents with good motor speed and have the electric-magnetic transmission system in what would correspond to a high-speed position in a sliding gearset. The cars always had several reserve electrical positions for the work.

Electric Brake's Value

The mountain work of the trip demonstrated the value of the electric brake which, when applied, immediately slows the car to 15 miles per hour. This brake is applied by the small lever on the steering wheel by which you start the motor, give the different electrical connections for the gearset and apply the electrical brake, all three on a lever but little longer than the throttle lever generally used. The electrical brake is not only easy to operate, but conserves the two sets of rear wheel friction brakes very materially. There was not a single instance of any trouble with the electric-magnetic systems of the cars on the entire trip.

—

Slaker Stover Sales Mgr.

JANESVILLE, WIS., Sept. 9—C. S. Slaker, head of the sales department of the Janesville Machine Co., Janesville, Wis., has resigned to become general sales manager of the Stover Engine & Mfg. Co., Freeport, Ill., which is the recent consolidation of the Stover Engine Works and Stover Mfg. Co.

Trucks Transport 2000 Troops

—

Carry Men and Equipment 200 Miles in 32 Hours—Use 132 Motor Trucks

SAN ANTONIO, TEXAS, Sept. 8—One of the most notable tests of army motor trucks was finished this morning when two thousand men and officers and equipment of the First and Second Kansas Infantry regiments arrived at Fort Sam Houston from Eagle Pass. The distance of approximately two hundred miles by the route traveled was covered in thirty-two hours actual running time. The transportation train consisted of 132 motor trucks. It is stated that this movement establishes a new record for rapid overland transportation of troops. Two all-night camps were made on the trip—one at La Pryor and the other at Castroville. The finish to Fort Sam Houston could easily have been made last evening, but it was decided to spend the night at Castroville, about thirty miles out, and bring the troops into camp fresh this morning.

Major General G. Frederick Funston met the troops at Castroville last evening. He expressed himself as delighted with the success of the truck movement.

Maxwell Earnings Gain 135 Per Cent

(*Continued from page* 425)

well Motor Co., Inc., during the past fiscal year shows an increase of 88 per cent over the sales of previous year. The manufacturing facilities of the factories at Dayton, Ohio, Newcastle, Ind., and Detroit, Mich., have been increased so that the company is now in position to produce more than 100,000 cars per annum.

Sales in August, 1916, the first month of the present fiscal year, show a substantial increase over the same period last year.

Aitken Makes Clean Sweep

Takes 20, 50 and 100-Mile Hoosier Events — Rickenbacher Breaks Wheel

INDIANAPOLIS SPEEDWAY, Sept. 9 — Johnny Aitken won all three races here to-day. Going into the 100-mile event, the third on the card, after having taken both the 20-mile and 50-mile dashes, his Peugeot showed the way, and with the confidence gained in his two earlier wins, Aitken jumped into the lead. However, Rickenbacher had kept his Maxwell out of the first two races purposely to save it for the one in which points toward the season's championship were to be awarded. Aitken found Rick crowding him hard and it was a battle royal between the two, who paced the field and kept well in the lead most of the time.

Aitken lead, but never for more than 100 ft., up to the end of the twenty-third lap, when Rickenbacher plunged out in front for one circuit of the track, Aitken heading him on the next circuit. Aitken held the lead until the thirty-third lap, then Rickenbacher led for one circuit, Aitken going into the lead again for two laps, or up to the 90-mile post.

It was on the next lap after this that the steering arm on the right wheel of the Peugeot broke and Rickenbacher began to walk away from Aitken as if the latter was tied. Pit attendants had signalled Rick to watch his right rear wheel, which was wobbling considerably and proved his undoing just when victory seemed within his reach, for Aitken was in serious trouble.

With but little more than 5 miles to go and when he was leading Aitken by almost a mile, Rick came out of the west turn into the homestretch at high speed and his right rear wheel collapsed and this caused the left rear tire to go. Much credit is due Rickenbacher for his masterly control of the Maxwell under these conditions. His car careened first right, then left, then right again and just when four cars seemed about to hit him broadside, for he was directly across the track, the Maxwell began sliding backwards and just in the nick of time gave the right of way to the cars bearing down upon it. Rickenbacher and his mechanic, George Henderson, were in their seats when the car came to a standstill and the cheers that greeted them as they walked to the pits was equal to that ever accorded any winner. Aitken drove the last eight miles with only one

Start of 100-mile race at Indianapolis. Carl Fisher is pacing the field in a Packard

Aitken and Hughes in sensational finish of 50-mile event, 27/100 seconds apart

front wheel attached to his steering apparatus.

Attendance Not Large

Indianapolis appeared to have been surfeited with entertainment, the State fair having closed yesterday, for there did not seem to be over 10,000 to 12,000 present at the races, which were the fastest ever seen on the Indianapolis track up to the time Aitken broke his steering knuckle and had to slow down. At that the 100-mile dash was considerably faster than the 300-mile event last Memorial Day and nearly equalled De Palma's speed when he won last year. The 20 and 50-mile events were won at 95.08 and 91.83 miles per hour, respectively.

The 100-mile race was characterized by two battles, that of Rickenbacher and Aitken and one between D'Alene and Hughes. From the thirtieth to the ninetieth mile Hughes had been fighting D'Alene for third place and when Rickenbacher wrecked Hughes jumped into Rick's place, passing D'Alene in the home stretch.

George Buzane, one of the surprises of the Cincinnati derby, where he won fourth place, repeated to-day. He had the pole position at the start, having drawn No. 1, and was soon in eighth place after the race started. However, at the end of 20 miles Milton docked his Duesenberg with ignition trouble and Buzane jumped into seventh place, just inside the prize money. De Palma's and Lewis' stops for tires at the 72-mile point gave Buzane fifth position and the falling of Rickenbacher put him in fourth, where he finished.

In the 20-mile event Aitken took the lead from the start and won at 95.08 miles per hour, although Wilcox gave him a hard battle, finishing only 0.33 sec. behind. Chevrolet drove the Sunbeam that Galvin took third money in at Cincinnati last Monday into third place.

In the 50-mile dash Wilcox, in a Premier, lead the field for six laps, then gave way to Aitken. Hughes lead the field in the fifteenth lap, but relinquished it to Aitken after one circuit of the track, but crowded the Peugeot close and finished 0.27 sec. behind Aitken.

It was an afternoon of spectacular finishes for each race. Not more than a car length decided between first and second places in the 20 and 50-mile events, and then in the 100-mile race Aitken stopped at the first pit on his last lap, coasting across the line when he got the checkered flag. Ralph De Palma, who drove Merz's Peugeot, kept running, but said after the race that it seemed to want to climb over the rail all the time. It seemed odd to see De Palma in the Peugeot blue; it made one lonesome for the Mercedes, which was too badly broken at Cincinnati last Monday to participate here. Christiaens did not start, his Sunbeam being disabled.

Aitken used Oilzum in the Cincinnati race last week instead of castor oil, as reported.

*Six cylinders; all others four cylinders.

How the Ford Racers Were Rebuilt

Some Resembled Peugeots and Others Wired Together

By Wallace Blood

Taking the steeply banked curve on the Chicago track. The rebuilt Fords sailed high up on the incline

Harvey's rebuilt car. It looked more like a Peugeot than the original Detroit one-a-minute creation

CHICAGO SPEEDWAY, Sept. 10 — Hay wire, binding twine, trunk straps, junk parts and mechanical ingenuity, combined with more-or-less semblances of Ford cars, went to make up the creations which took part in the Ford race to-day, and a more motley assortment of reconstructed flivvers has never been seen. The springs were underslung and overslung—two cars were entirely without springs. There were distributers, special magnetos and ordinary Ford magnetos, cast-iron pistons and aluminum pistons, skeleton bodies and streamline racing types. Even that which was previously considered impossible was accomplished. Fords were disguised so that all evidence of their birthright was effaced.

The greatest interest hinged on car No. 1, which took first money in two of the races and showed close to 80 miles an hour in practice. It is a Bob Burman and Jack Gable designed replica of a Peugeot, built in his father's garage at Oak Park, Ill., by Paul Harvey, the driver. It was this garage in which Burman and Gable kept their cars prior to the 1915 Chicago race and credit is given them for much of the car's design. The car got into the race because it has a Ford block, gearset and axle. Otherwise it was a special racing job all the way through. A sum amounting to well over $1,500 is said to have been spent on its construction. More credit should be given the entries who had limited capital and spent their sums on alterations which gave their Fords the most speed.

Harvey's Car a Masterpiece

Harvey's car was a masterpiece of workmanship and is prophetic of what may come in cars with small motors capable of attaining high speeds. In action it was like a Schubert symphony, smooth and harmonious. The block bore the Ford stamp. Internally, however, the motor had more bore and stroke, larger valves, racing camshaft—in fact, is so altered that there was little Ford left. The frame is hung low on heavy cantilevers. The exhaust is carried out through four straight pipes into an exhaust tube on the side which is large enough to take care of a 300 cu. in. motor. The magneto is Bosch, there is a Master carbureter, Rudge-Whitworth racing wheels and Goodyear cord tires.

The car which bore No. 37, built and driven by B. F. Davis, Paris, Ill., is a typical representative of how a Ford motor may be coupled with hybrid parts to make a car which is capable of close to 70 miles per hour. Davis won the 30-mile Illinois State championship, but unfortunately broke a rod in the free-for-all when he was running close second to Harvey.

The motor is a Ford. The bore is the same and the stroke. Valves were enlarged to 1⅝ in., Rich tungstens being used. The carbureter is a Master and the magneto a Bosch. The camshaft was not altered. A Monroe frame is used to undersling a Scripps-Booth axle on the front and a combination Ford and Scripps-Booth axle on the rear. This combination includes a Ford differential and housing with Scripps-Booth floating axle. The high Champion radiator and formidable-looking streamline body gave the car a full-fledged racing appearance.

Another car of similar lines was No. 39, built by H. B. Wilson, Dewitt, Ill. Mechanical trouble made it a poor contender in the races, but in preliminary trials it showed commendable speed. Here, too, a Champion radiator heads a symmetrical streamline body. Bosch and Master equipment is evident and Universal Welding Co. wire wheels are fitted. The builder ground his camshaft to quicken the lift and drop and installed lynite pistons.

Methods of Lowering Frame

The most varied of all alterations were the methods of lowering the frame. Car No. 38, Chic Wheeler, Des Plaines, Ill., lowered the front with a special axle, as shown in Fig. 1. In the rear, refer to

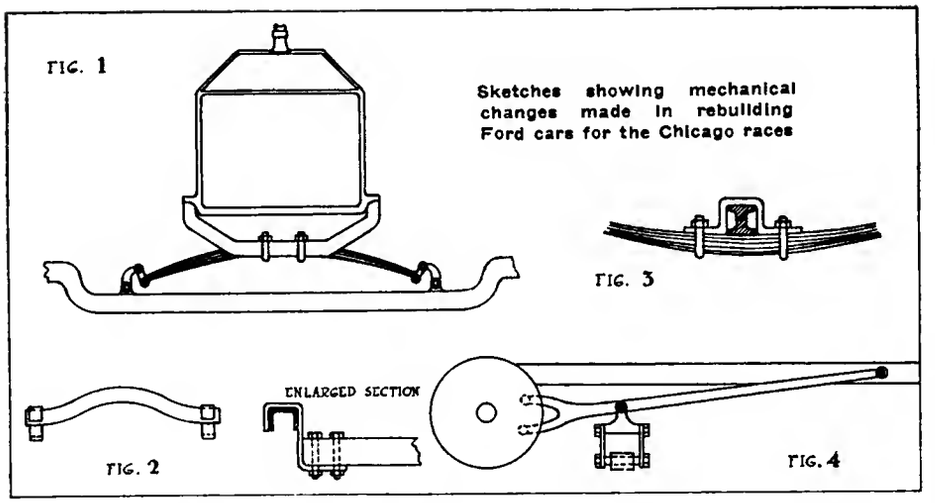

Fig. 2, he sawed off 4 in. from the frame on each side and suspended the regular Ford rear-spring hanger on two goosenecks made out of flat bar steel. This gave him a frame 4 in. lower than is found in the stock Ford. He also used Bosch for ignition and the carbureter is a Rayfield.

Another unique method of lowering the frame was found in car No. 10, driven by Hugo Zeeh, Oak Park, Ill. As shown in Fig. 3, the front axle was underslung by the use of a U-shaped piece of flat steel stock over the axle and fastened to the springs with clips as shown. In the rear, he utilized the brake arm studs in the rear axle hub to fasten a forked bar from the axle to the frame as shown in Fig. 4. About two in. forward from the fork he bolted shackles and suspended the transverse spring from these. These alterations gave him about 4 in. drop.

Car No. 6, which finished third in the free-for-all, certainly performed differently than it looked. It was an old Ford in the first place, and had seen much service. There was nothing much special about it except that the axle was geared up and the timing set ahead. Underneath the gearset was a battered sheet metal pan, "to keep the oil from the track," according to Henry Mueller, Chicago, the driver and owner. This pan was fastened to the frame with hay wire—all in all a crude looking job. But the car had the stuff and the prize won certainly bought that battered pan and the hay wire.

Hay Wire Holds Hood

Car No. 3, V. W. Jury, Chicago, promised to be a strong contender. One little oversight put it in the discard, and that was that the driver relied on hood fasteners instead of a strap. He made four stops in the 50-mile event to fasten down the hood and finally secured it in place with a dose of the ever-present hay wire.

Car No. 24, driven by Emil Laznasky, Mt. Prospect, Ill., which got second place in the big race, had about as little done to it to make it fast as any of the contenders who placed. The driver, who was also the builder, against the advice of friends, removed the magnets from the flywheel of the Ford motor and installed an Atwater-Kent distributing system. He attributes his success to this disregard of his friends' advice. About the only other change from a regular Ford was the use of a Master carbureter and a V-shaped tank soldered to the front of the radiator to give additional water capacity.

A majority of the cars in the race were provided with some kind of an extra carrying space for water. There were tanks soldered on the front and rear, of all shapes and degrees.

What few there were who did not alter the radiators were frequent visitors to the pits for new water supply.

One Burned Kerosene

Car No. 40 was entered by J. W. Duntley, originator of pneumatic tools and well-known inventor. It embodied his latest invention, a kerosene burning atomizer. The device will start a Ford cold on the second or third turn of the crank. It weighs but 1¼ lb. There are sixteen parts which go to make up the complete device. Kerosene is admitted to the atomizer into an ordinary float chamber, but that is all of the device which resembles a carbureter. The fuel is sucked into a tube in which there are a series of slits for atomizing. Over this tube is another sleeve with more slits. Mixture is made rich or lean by matching up the slits, for a lean mixture and all of them for a real rich mixture. This operation is controlled by a lever on the steering column. The throttle is a dished disk which slides over the outside sleeve, thus regulating the amount of fuel admitted to the motor. The car entered the race on three-quarters kerosene and one-quarter gasoline, but the atomizer will handle straight kerosene with good results. Duntley offered $200 for any other kerosene burning Ford which would race him, but did not get an acceptance.

As a summary, speed seemed to have been attained by the use of special magnetos or distributers, carbureters of larger capacity than the Ford, lowered frames, higher gear ratios, and timing set ahead, with a few of the camshafts special and some of them ground to sharper points by the builders.

Effect of the War on Aeroplane Engine Design

(*Continued from page* 433)

to allow for the increased engine load when laying his plans.

Several of the foremost engineers have had under consideration for some time the construction of huge battle planes, but have had to let them rest until the certainty of their getting an engine of the power capable of driving a machine of this size. In most cases, the question of final drive for propellers is undecided, as with a unit of 400 or 500 hp., the proper location for it would be inside the fuselage, where it could be under observation and not an object of head resistance.

In this case the question of gearing would not be of moment, as in all likelihood the drive would be through shafts to two outboard propellers, similar to the Zeppelin method of drive.

On some of the smaller engines of 250 hp., the question of cooling has been worked out to very nearly the limit, and a finished radiator for a Rolls-Royce of this power only weighs 62½ to 63 lb., with a correspondingly small amount of water.

In conclusion, the writer wishes to emphasize the fact that in designing an engine for aeroplane use, consideration should be given to the service that this particular engine is intended for, and that if possible there should always be co-operation between the designers of the engine and the plane, for while it is slower work, it certainly will give greater satisfaction in the end, and should produce better results. In this way it is often possible to eliminate certain weights by lightening up on various parts, and incorporating other features that will facilitate and simplify the work as a whole. Numerous incidents can be cited where this has made a pronounced improvement.

Factory Miscellany

Lexington Adds—The Lexington-Howard Motor Co., Connersville, Ind., is planning a one-story addition 125 by 200 ft.

Duryea May Locate in Baltimore—The Duryea Motors Co., Philadelphia, Pa., is seeking a site for a plant in or near Baltimore.

Pilot to Double Capacity—The Pilot Motor Car Co., Richmond, Ind., is having plans prepared for doubling the capacity of its plant.

Alter to Build in Grand Haven—The Alter Motor Car Co., Plymouth, Mich., is planning to erect a factory, 60 by 400 ft., at Grand Haven, Mich.

Field Motor's Factory—The Field Motor Co., Grand Rapids, Mich., will build a one-story factory, 50 by 100 ft., for the manufacture of gasoline and kerosene engines.

Dunlop Tire to Build—The Dunlop Tire & Rubber Goods Co., Toronto, Ont., is contemplating the erection of a factory building to be of brick and mill construction.

Guide Lamp Adds—The Guide Motor Lamp Co., 114th and Madison Streets, Cleveland, is building a one-story brick addition to the present building which will cost about $11,000.

Sherman Carbureter Co. Formed—The Sherman Carbureter Co., Buffalo, N. Y., has been formed to manufacture carbureters and automobile supplies. W. H. Grever, 146 Hughes Avenue, and R. C. Harrison and J. F. Sherman, Buffalo, are the incorporators.

International Rubber to Build—The International India Rubber Corp., South Bend, Ind., has contracted for the erection of the first unit of its tire factory. The dimension of the building will be 382 by 80 ft., and will contain 28,700 sq. ft. of floor space.

Canadian Factory Items—A contract has been given for the erection of a factory in Oshawa, Ont., for the Chevrolet Motor Co., to cost $40,000. The Chevrolet company will also build another structure there at a cost of $50,000.

The Motor Products Co. will build a plant at Walkerville, Ont.

Mitchell Wagon Enlarges—The Mitchell Wagon Co., Racine, Wis., manufacturer of automobile bodies, is enlarging its operating departments to bring the output up to the mark required by its contracts, the principal one being with the Mitchell Motors Co. The Mitchell output is being largely increased, bringing an unusually heavy demand upon the body makers.

Tire Fabric Plant for Niles—Work is in progress in Niles, Mich., on the construction of what is said to be the first tire-fabric plant west of the Alleghenies. The plant is being built for the Towar Cotton Mills, Inc. Officers of the company include: President, S. C. Towar, who has been sales manager of the Acme Belting Co., Niles, and secretary and treasurer, G. A. Merritt, Detroit.

Wis. Factory Items—The Waukesha Motor Co., Waukesha, is having plans prepared for a new administration building, to be of fireproof construction, 36 by 132 ft. in size, two stories and basement. The completion of the new offices will release considerable floor space for manufacturing purposes, which is badly needed because of the great rush of orders.

To temporarily relieve the congestion in the plant and pending the completion of a mammoth new assembling shop, the Falls Motors Corp., Sheboygan Falls, has erected a large circus tent in which assembling operations will be carried on night and day for at least 2 months. The company added fifty skilled mechanics to the force during last week and is taking competent help as rapidly as it presents itself.

F. W. D. Tractor Seeks Plant Location—The Four Wheel Drive Tractor Co., originally organized at Antigo, Wis., and later by Clintonville, Wis., capital, is considering propositions from no less than six large Wisconsin cities for the location of the works, which is about to be undertaken. Among the bidders for the industry are Oshkosh, Appleton, Green Bay, Wausau and Fond du Lac.

Work Started on Stewart-Warner Addition—Work now is well under way on the first of a large group of new iron and brass foundry buildings at the Warner works of the Stewart-Warner Speedometer Corp., Beloit, Wis. The work of moving the equipment of the present shops to the recently enlarger main works in Chicago has been completed. Henceforth the Beloit works will devote all attention to the manufacturing of raw material, and finishing, assembling and other final processes are concentrated in Chicago. The new iron foundry will be 180 by 480 ft., and other buildings in proportion. Harold Hemenway, East Moline, Ill., has been appointed general superintendent at Beloit to succeed A. E. Moon, who is promoted to an executive position in Chicago.

The Automobile Calendar

ASSOCIATIONS

Sept. 25—Indianapolis, Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.
Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.
Oct. 2-7 — Kansas City, Mo., Dealers' Show, American Royal Live Stock Show; Kansas City M. C. Dealers' Assn.
Oct. 13—Flint, Mich., Fall Meeting National Assn. of Automobile Accessory Jobbers.
Dec. 2-9—Electricians' Countrywide Celebration.

CONTESTS

Sept. 16—Providence Speedway Race.
Sept. 18—North Yakima, Wash., Track Race, Washington State Fair.
Sept. 29—Trenton, N. J., Inter-State Fair. H. P. Murphy, Racing Sec.
Sept. 30—Astor Cup Race, 250 miles, Sheepshead Bay Speedway, Sheepshead Bay, N. Y.
Oct. 7—Philadelphia Speedway Race.
Oct. 7—Omaha Speedway Race.
Oct. 14 — Chicago Speedway Race.
Oct. 19—Indianapolis, Ind., Race, Indianapolis Motor Speedway.
Oct. 21 — Kalamazoo, Mich., Track Races, Kalamazoo, Motor Speedway.
Oct. 22-23—Los Angeles, Cal., Commercial Car Reliability Tour.
Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.
April, 1917—Los Angeles to Salt Lake City Road Race.

SHOWS

Sept. 10-16 — Milwaukee, Wis., Show, Wisconsin State Fair, Machinery Bldg.
Sept. 25-30—Salem, Ore., State Fair, Joseph M. Rieg, manager.
Oct. 14 - 31 — Dallas, Texas, Show, State Fair.
Jan.—First Pan-American Aeronautic Exposition, New York City; Aero Club of America, American Society of Aeronautic Engineers, Pan-American Aeronautic Federations.
Jan. 6-13, 1917—New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.
Jan. 13 - 20 — Montreal, Que., Show, Montreal Automobile Trade Assn.
Jan. 20-27—Montreal, Que., Automobile Trade Assn.
Jan. 27-Feb. 3, 1917 — Chicago, Ill, Show, Coliseum, National Automobile Chamber of Commerce.
Feb.—Newark, N. J., Show, First Regiment Armory.
Feb.—St. Louis, Mo., Show, Auto Manufacturers, and Dealers' Assn.
Feb. 3-10—Minneapolis, Minn., Show, Minneapolis Automobile Trade Assn.
Feb. 26-March 3—Omaha, Neb., Show; Auditorium, Omaha Automobile Show Assn.
March 3-10 — Boston, Mass., Show, Mechanics' Bldg., Boston Automobile Dealers' Assn.
March 6-10—Ft. Dodge, Iowa, Northern Iowa Show, New Terminal Warehouse, G. W. Tremain, Secretary.

TRACTOR

Sept. 11-16 — Milwaukee, Wis., Fall Show, Wisconsin State Fair, Milwaukee Automobile Dealers.
Oct. 14-29—Dallas, Tex., Demonstration, Texas State Fair.

The Week in the Industry

Baltimore Trade Items—H. S. Block, who for some years has been the Chandler distributor for Maryland, is now looking after the retail business for the Chandler in Baltimore at 1014 Morton Street.

The Beam Motor Car Co., 1114 Cathedral Street, former Chandler agent, is handling the Allen and the Premier.

The Wilson Motor Co., 605 West North Avenue, former Mitchell and Maxwell distributor, is now handling the Liberty and the Grant lines.

Day-Elder motor trucks are being handled in Baltimore, with the showrooms in the new Mid-City Garage, 29 South Charles Street. H. H. Day is the Baltimore and Southern distributor and J. A. Muir is in charge of the local sales department.

Bowser Booster Out—The *Bowser Booster* is the name of a new publication at the S. F. Bowser Tank & Pump Company, Fort Wayne, Ind. The paper is intended to deal entirely with the activities of the factory and office, as the *Bowser Booster* is printed in the interests of the salesmen.

Philadelphia Items—The Wagner Electric Mfg. Co., St. Louis, has opened a branch and service station at 1430 Vine Street, Philadelphia, in charge of N. A. McCoy.

B. F. Hoffman, sales manager for the Ford Motor Co., Philadelphia, will leave that company about Oct. 1 and open up the Hoffman Motor Co. at 235 North Broad Street, the quarters now occupied by the Buick agency. Mr. Hoffman will handle Ford cars under the new plan.

Pacific Coast News—The Al. G. Faulkner Co., Los Angeles, Cal., southern California and Arizona distributor of the Marmon, will occupy a new two-story brick and stone building at the corner of Figuroa and Seventeenth Streets on or before Oct. 1.

Both the wholesale and retail selling privileges on the Firestone tire in Portland, Ore., were conferred by F. W. Thatcher, manager of the Portland branch of the company, to B. E. Boone & Co., retail Chevrolet dealer. The Firestone branch will retain its present quarters at 65 Park Street, North, and will take care of the territory outside Portland, as in the past, and assist the new organization to obtain additional city business.

Columbus News Items—E. P. Strang, district manager of the Deneen Motor Co., a newcomer in the motor truck field, arrived in Columbus recently for the purpose of establishing an agency.

The Owen Magnetic Motor Car Co., located on North High Street, Columbus, has taken the central Ohio agency for the Velie.

E. H. Huffman, 105 East Town Street, Columbus, has taken the local agency for the Stephens Six.

Cruikshank, Son & Robinson is the name of a new retail firm at 402 Schultz Building which will handle the Argo and Pathfinder in central Ohio territory.

The Ohio Metz-Elcar Co., 211 North Fourth Street, Columbus, has taken Ohio distribution for the Metz and Elcar. W. A. Albaugh is general manager.

St. Louis Trade Happenings—A. P. Seigmund, St. Louis, has been appointed manager of the truck department of the Detroit Electric Car Co., Twentieth and Locust Streets, that city.

The Gibson Motor Car Co., the Dodge distributor in Webster Groves a St. Louis suburb, is erecting a brick and tile showroom and service department on Lockwood Avenue.

The Ebbeler Motor Car Co., St. Louis, has taken the agency for the Mitchell cars.

A. G. Cameron, Dallas, Tex., is the new manager of the St. Louis branch of the Goodyear Tire & Rubber Co. Mr. Cameron has been in the Goodyear service as Dallas manager 3 years. He succeeds W. E. Finney, transferred.

G. C. Brinkmann, St. Louis, has resumed the management of the Brinkmann Motor Co., Maxwell distributor.

The McQuay-Norris Mfg. Co., St. Louis, has added the following mechanical engineers to its sales force: H. H. Cummings, Chicago; R. B. Pratt, Milwaukee; F. L. Stevenson, Detroit.

R. W. Immasche, St. Louis, recently appointed distributor for Jordan cars, will incorporate under the name The Jordan Motor Sales Co.

G. H. Scott, Columbia, Mo., manager of the branch in that city of the Hudson-Phillips Motor Car Co. of St. Louis, has been made manager of the company's wholesale department, vice L. T. Hudson, who resigned to accept a position in Memphis.

W. C. Capen, St. Louis, manager of the White branch in that city, has been transferred to an executive position at the factory in Cleveland. He will be succeeded in St. Louis by G. E. Armstrong, who has been with the Locomobile Co. in New York City and at the factory.

Canadian Trade News—Aubrey Hurst, 32 Front Street, West, Toronto, Ont., has been appointed sole Canadian representative for the Detroit Weatherproof Body Co., Detroit.

The Breen Motor Co., Winnipeg, Man., has been appointed sole agent in Winnipeg for the Chalmers car, recently handled by Joseph Maw & Co.

Mountain Trade—The Headington Auto Co., Denver, Metz, Inter-State, Enger and H. A. Lozier distributer for Colorado and Wyoming, has added the Sun distributing agency for the same territory.

The J. S. Morrison Auto Co., Denver, Allen and Oakland distributer for Colorado and Wyoming, has given up the Oakland and is handling the Allen exclusively.

The Norton-Buick Co., Denver, Buick distributer for Colorado and southern Wyoming, has secured the G. M. C. truck-distributing agency for the same territory. The headquarters will soon be moved from 25 East Colfax Avenue to 1535 Lincoln Street.

The Turner-Deigle Motor Co., Denver, is the new name for the Turner Commercial Auto Equipment Co., formerly distributer for the Smith Form-a-Truck, at 455 Broadway, which has given up that business and taken one of the local Ford agencies.

Lee McGee, Denver, has opened a Stephens distributing agency for Colorado, Wyoming and New Mexico at 1908-1914 Broadway.

The Tibbals-Anderson Motor Co., Denver, Jackson distributer for Colorado, Wyoming and New Mexico, with headquarters at 1188 Broadway, has added the Elcar distributing agency for the same territory.

The United Motor Sales Co., Denver, has opened a Ford agency and service station at 153-155 Broadway.

The Beardsley Electric Co., Denver, is the name of a Colorado distributing agency for the Beardsley recently opened at 1431-1433 Cleveland Place. The business is in charge of G. A. Showers, and A. K. Ancker is sales manager.

S. W. News Items—C. L. Jarrett, Springfield, Mo., will distribute the Chevrolet in that territory.

The Martin Motor Co., Springfield, Mo., has been organized to handle Maxwell in the Springfield territory.

The Howard & Murphy Motor Co., Kansas City, Mo., has employed E. J. England, formerly sales manager of the Karshner Motor Car Co., as sales manager.

Each nationality has its admirable characteristics. They fuse and blend in America's great melting pot, and there emerges a new national type combining the excellences of all—the American.

Motors are made in many lands, with characteristic features of design. France, England, Germany, Italy, America—each contributes, through its notable engineers, to the world's motor experience. By means of its customer-connections with over 150 manufacturers of automobiles and trucks in both Europe and America, the Continental Motors Company maintains unbroken communication with every reliable source of motor experience in the world.

Into the Continental crucible pours all this wealth of engineering achievement. Purged of dross, freed from all freakishness, refined and perfected by its own superb corps of engineering experts, there emerges that new type combining in standardized form the excellences of all — the world-famous Continental Motor.

CONTINENTAL MOTORS COMPANY

Detroit, Michigan	Detroit, Muskegon

Largest exclusive motor manufacturers in the world.

The Value and Cost of Our Speedometer Service

Our chain of direct factory branches and service stations which covers the country plus our large field organization of service men costs us more per speedometer than any reduction any other speedometer manufacturer might offer you.

And our additional overhead serves you—not us.

As 95% of the automobile manufacturers willingly pay the difference we must be on the right track.

VOL. XXXV NEW YORK—THURSDAY, SEPTEMBER 21, 1916—CHICAGO NO. 12

48,750 Studebakers in 8 Months

1710 More Than in Whole Year of 1915—Output Increasing

DETROIT, MICH., Sept. 16—The Studebaker Corp., for the first eight months of 1916, ending Aug. 31, has sold more cars than for the entire 1915 year. In number of cars, 48,750 Studebakers were sold from Jan. 1 to Aug. 31 of this year, as compared with 47,040 for the whole of last year, a gain of 1710.

At the present rate, 1916 sales will be 55.4 per cent greater than 1915, or about 73,125 cars, meaning an aggregate gain for 1916 over the previous year of 26,085 cars, if the present rate is maintained. As a matter of fact, however, it is practically certain that the balance in favor of 1916 over 1915 will be greater than the estimate just given, for the output is being steadily increased, and the factory reports sales for the last four months of this year in larger proportion than for the whole eight months of this year.

100,000 Cars Planned

It is believed that Studebaker will sell about 80,000 cars, and, with recently authorized factory extensions, including additional buildings and equipment, will enable the production of 100,000 cars, that being the mark set for 1917.

—

Monteith F. & H. Manager

COLUMBUS, OHIO, Sept. 16—John C. Monteith has been named general manager of the Phelps Mfg. Co., this city, maker of the F. & H. wire wheel.

—

Bill and Decou Resign from Nash Motors Co.

KENOSHA, WIS., Sept. 16—Louis H. Bill of the Nash Motors Co., formerly the Thos. B. Jeffery Co., this city, has resigned as general manager, effective Oct. 1. He expects to return to his home in San Francisco. Jerry Decou, who has been general factory manager, resigned Sept. 15 and is succeeded by John Bjorn, formerly superintendent. Mr. Bill's successor has not been announced. Bill is one of the old men in the trade having been branch manager of the H. A. Lozier Co. in the bicycle trade, becoming branch manager of the Jeffery company in 1905 and entering the factory in 1913.

—

Friend Returns to Mitchell as President

RACINE, WIS., Sept. 20—*Special Telegram*—Otis C. Friend has returned to the Mitchell Motor Co., Inc., as president and general manager, succeeding H. L. McLaren, who resigned 2 months ago. John W. Bate is vice-president and chief engineer.

Mr. Friend left the Mitchell company to become vice-president and general manager of the United Motors Corp., but assumes his new duties with the Mitchell company at once.

Other Officers

W. H. Armstrong is secretary and treasurer and F. L. Mitchell, formerly treasurer, becomes comptroller. Mr. McLaren remains president of the Racine Tire Co.

Mr. Friend has been connected with the automobile industry for nearly a score of years beginning with the Chicago sales of the Locomobile. He joined the sales force of the Chicago Mitchell agency in 1900 and later handled Mitchells as the firm of Brown & Friend of Milwaukee. Mr. Friend then became purchasing agent of the Mitchell-Lewis factory and was successively assistant to J. W. Bate and general superintendent of shops. On Aug. 1 announcement was made that he had resigned as sales manager of the Mitchell-Lewis company to become vice-president of the United Motors Corp.

Saxon Stock Placed on 7% Basis

Fiscal Year Profits $1,316,272—Output 25,500 Cars, 15,651 Gain

NEW YORK CITY, Sept. 20—The dividend of the Saxon Motor Car Corp. has been increased from 6 to 7 per cent. This is put into effect by the declaration of a quarterly payment of 1¾ per cent, payable Oct. 2. Net profits for the year ending June 30 were reported as $1,316,272, or approximately $116,000 greater than the estimates made in official circles during the last quarter of the company's fiscal year, and equivalent to nearly $22 a share on the $6,000,000 stock. The first dividend was paid last July.

The output of the company during the fiscal year was 25,500 cars, an increase of 15,651 over the preceding year when 9843 cars were built.

President Harry W. Ford, in his annual statement to stockholders, reports that the company has on file contracts with dealers for 50,000 cars, with a number of territories still to be closed.

SAXON BALANCE SHEET—JUNE 30, 1916

Hudson Coast-to-Coast Record

Super-Six Covers 3476 Miles in 5 Days, 3 Hours and 31 Min.

TRANSCONTINENTAL RECORDS

Car	Driver	Time Days	Hrs.	Min.	Date
Hudson	Paterson .. Mulford ... Vincent ...	5	3	31	Sept., 1916
Marmon	Stevens ...	5	18	30	July, 1916
Cadillac	Baker	7	11	52	May, 1916
Stutz	Baker.	11	7	15	May, 1915

NEW YORK CITY, Sept. 19—The transcontinental record has been lowered 14 hr. 59 min. by a Hudson Super-six. The speed from San Francisco to New York averaged 27.14 m.p.h. and the distance was 3476 miles. The Hudson car reached New York 5 days, 3 hr. and 31 min. after leaving San Francisco. The best railroad time across the continent is 3 days, 21 hr. 45 min., according to railroad officials here.

Left Wednesday, Sept. 13

The car left San Francisco with A. H. Patterson of Stockton, Cal., at the wheel at 12.01 a. m. Wednesday, Sept. 13. It arrived at Columbus Circle the following Monday at 6.31 a. m. Patterson drove to Elko, Nev., Mulford took the wheel there and drove to Laramie, Wyo. Patterson again took the wheel and brought the car to South Bend, Ind. C. H. Vincent drove the last lap of 910 miles into New York. With these men in the car were W. Sturm and L. Kalinsky.

No Tire Trouble

The trip was made on United States Royal Cord tires and came through without trouble.

Following is the check of Hudson Transcontinental car:

Left San Francisco, Sept. 13, 12.01 a. m., checked by L. J. Pinkson, automobile editor San Francisco *Chronicle* and W. C. Kieffer, general agent Wells Fargo & Co.

Carson City, Sept. 13, 7.25 a. m., 253 miles, A. C. Cunningham, blacksmith.

Ogden, Nev., Sept. 14, 10.05 a. m., 842 miles, W. W. Fleetwood, clergyman and F. W. Wheeby, dentist.

Laramie, Wyo., Sept. 15, 5.39 a. m., 1395 miles, G. T. Glessner, dentist and E. W. Johnson, undertaker.

North Platt, Neb., Sept. 15, 2.45 p. m., 1560 miles, J. L. Souder and L. A. Spencer.

Omaha, Neb., Sept. 16, 2.05 a. m., 1844 miles, A. P. Ginon, lumber dealer.

Des Moines, Iowa, Sept. 16, 10.36 a. m., 2029 miles, Dr. D. Lecon, automobile editor *Register*, and H. E. Ward, newspaperman.

Joliet, Ill., Sept. 16, 8.25 p. m., 2381 miles, G. S. Jackson, manager Baskiel Motor Co.

South Bend, Ind., Sept. 16, 12 midnight, 2491 miles, J. F. Cole, president National Co.

Buffalo, N. Y., Sept. 17, 2.30 p. m., 2971 miles, H. M. Wall, president New York State Motor Federation.

New York, Sept. 18, 6.31 a. m., James Hemstreet, American Automobile Assn.

Signal-Commerce Truck Merger Abandoned

DETROIT, MICH., Sept. 19—The merging of the Signal Motor Truck Co. and the Commerce Motor Truck Co. here under the name of Signal-Commerce Motor Truck Co. has been abandoned. It had been the plan to take over the two properties and incorporate under New York State laws with a capital stock of $600,000, shares of no par value.

Thomas Neal, president of the Signal concern and at one time head of the General Motors Co., was to have been president of the merger and W. E. Parker, president of the Commerce company was to have been vice-president of the proposition.

The two motor truck manufacturing concerns involved in the negotiations will revert to their original individual identities and each will continue to operate separately as heretofore.

—

Ruse, Production Expert, Dies

KENOSHA, WIS., Sept. 16—John W. Ruse, one of the best known production experts in the automobile industry, died here yesterday of acute dilation of the heart after a brief illness. Mr. Ruse was for 8 years identified with the Buick Motors Co. at Flint, Mich., for the last 6 years as general superintendent. Several weeks ago he came here to become associated with C. W. Nash, president of the Nash Motors Co.

To Vote Fisk Capital Increase

Meeting Oct. 2, To Decide on Increase of $12,500,000 or Less

BOSTON, MASS., Sept. 18—Stockholders of the Fisk Rubber Co., will vote at a meeting on Oct. 2, on an increase of capital stock of $12,500,000. Of the new capital, $7,500,000 or less is to be first preferred, and $500,000 or less is to be second preferred.

The stockholders also will vote on authorizing an increase in the common stock by an amount necessary to take care of conversions of existing second preferred and proposed first and second preferred. A proposition to reduce the authorized capital of the company by $5,000,000, the amount of second preferred stock, series B, authorized a few months ago, but not issued, will be submitted.

First Preferred Convertible

The new first preferred stock, if authorized, may be converted into common stock prior to Jan. 1, 1922 at 125, four shares of common for five preferred, and from Jan. 1, 1922, to Dec. 31, 1926, at $150, four shares of common for six preferred. There is $2,000,000 second preferred stock now convertible into common up to Nov. 1, 1917, and the stockholders will be asked to approve an extension of this period until Nov. 1, 1923.

Holders of the present first preferred stock will be offered pro rata $5,000,000 of the new first convertible preferred at par and accrued dividends, while holders of the present second preferred and common stocks will be offered pro rata $2,500,000 of the new second preferred stock at par and accrued dividends.

Ralph Mulford at the wheel of the Hudson Super-six which established a new transcontinental record by traversing the 3476 miles from San Francisco to New York in 5 days, 3 hr. and 31 min.

S. A. E. Standards Men Meet

Straight Side Tires a Standards Possibility—Electric Units Mounting Problems

DETROIT, MICH., Sept. 18—Two meetings of S. A. E. standards committees were held last week. The newly formed tire and rim standards met for the first time and discussed matters relating to pneumatic and solid tires. It was agreed that there are strong probabilities that straight side tires can be made standard for the bulk of the sizes in use, though it is thought the clincher is better for the smallest diameters. There is still some debate as to whether or not the largest sizes in use can be made as satisfactorily in straight side as in clincher. The question will be discussed at the October meeting of the standards committee, which will be held in Washington probably about Oct. 18.

It was reported that the rim situation is improving and that a standard felloe band for passenger car wheels will soon be a practical possibility.

The other meeting was of the subcommittee on the standardization of starting motor and generator mountings. This committee has found its apparently simple task to be extremely complicated, and the members have some of them done a great deal of drafting room work in trying out existing engine drawings against standard mountings. Still more of this work will have to be done before a decision can be reached, but the members are giving so much time to the matter that a report is hoped for at the January meeting of the society. The main trouble is found in starting motor mountings, for the space available is usually much more limited than for the generator. It seems, however, certain that all engine makers will appreciate a standard greatly.

During the coming week the miscellaneous division will meet in Cleveland and the truck standards division meets again in New York before the end of the month.

—

Hatch Heads Perfection Spring Sales

DETROIT, MICH., Sept. 19—Charles Hatch, sales representative of the Perfection Spring Co. of Cleveland for the past 8 years, has been promoted to the position of sales manager of the company and appointed a member of the executive committee.

—

Hubbard Is Harris Engineering Co. V.-P.

BRIDGEPORT, CONN., Sept. 16—Franklin G. Hubbard has resigned as chief engineer of the mechanical department of the Western Electric Co. plant in Hawthorne, Ill., to become vice-president, a stockholder and director of the H. E. Harris Engineering Co., this city. The Harris company, in addition to the engineering business connected with its special machine tool and gage shops, turn out taps, dies, thread gages, ring and plug gages, tapping, grinding and notching machines, etc.

—

Three More M. & A. M. Members

NEW YORK CITY, Sept. 19—The three following concerns have been elected to membership in the Motor and Accessory Manufacturers: Au-To Compressor Co., manufacturer of air compressors, bumpers, tire holders, connecting rods, etc., 233 Mulberry Street, Wilmington, Ohio; F. W. Mann Co., manufacturer of automobile jacks, Milford, Mass.; and West Side Foundry Co., manufacturer of tire pumps, Troy, N. Y.

—

Buckwalter Is Timken Bearing Engineer

CANTON, OHIO, Sept. 16—T. V. Buckwalter has been appointed chief engineer of the Timken Roller Bearing Co., this city.

—

Myers with Fageol Motors Co.

DETROIT, MICH., Sept. 18—Cornelius T. Myers, who is engaged in consulting work on automobiles and tractors here, has been retained as consulting engineer by the Fageol Motors Co. of California. Mr. Myers recently resigned as manager of the Timken-David Brown Co., previous to which time he was mechanical engineer of the General Motors Co.

—

Woodruff Is Simplex Asst. Sales Mgr.

NEW YORK CITY, Sept. 16—The Simplex Automobile Co. has appointed A. A. Woodruff assistant sales manager, with offices at 60 Broadway. Mr. Woodruff will have charge of office routine and system and the spare and repair parts business. He will also remain manager of the body department.

—

Porter Is King Asst. Sales Mgr.

DETROIT, MICH., Sept. 16—Joseph Porter, who has been manager of the King Car Corp., New York City, has been appointed assistant sales manager by the King Motor Car Co., Detroit.

—

Mutual Motors Promotes Two

JACKSON, MICH., Sept. 19—D. B. Williams has been elected secretary of the Mutual Motors Co., this city, and will have entire direction and supervision of sales and advertising. Mr. Williams has been associated with President Handley of the company for several years.

W. T. Miller, formerly connected with the Willys-Overland Co., has been elected treasurer of the Mutual organization.

Beecroft Talks S. A. in Cleveland

75% of S.A.E. Section Attend —Akron and Toledo Well Represented

CLEVELAND, OHIO, Sept. 15—Over 75 per cent of the membership of the Cleveland section of the S. A. E. was present at the opening of the fall and winter season to-night, when David Beecroft, Directing Editor of THE AUTOMOBILE, gave an illustrated talk on automobile conditions in South America. Over 100 lantern slides showing roads, automobile salesrooms, garages, and country conditions in Argentine, Brazil and Uruguay, were shown. Many of the tire interests of Akron were represented, as were factories in Toledo and other outlying towns and cities.

The fact that 8.5 per cent of the entire automobile business of the fiscal year ending June 30 of the U. S. A. was export business shows the prominence which this branch of the work is attaining. The Argentine market for automobiles is particularly attractive to-day because of the poor wheat crop in Minnesota, the Dakotas, parts of western Canada, etc. A poor wheat crop in these sections means better prices for Argentine wheat. How Europe is watching the grain markets in North and South America was well illustrated by the fact that as soon as our wheat reports were published prices in Argentina started rising. One large automobile manufacturer received a cable order from his Buenos Aires representative the following day for more cars. The selling season in Argentina and Brazil opens in November and continues to March, so that any present increase in Argentine wheat is going to have a very substantial influence on the selling of our U. S. A. cars there during the next 8 months.

Larger Sales Expected

Until a few months ago Argentina had a very large percentage of her last wheat crop on hand. Argentina is not blessed with a great system of grain warehouses at railway depots, as in U. S. A., Canada and Australia. As a result, the farmer has stored much of his crop of the farm, holding it for higher prices. During the last 12 months the Argentine farmer has suffered with his wheat because Europe has been buying from U. S. A. and Canada in preference to South America, solely because of the shorter freight haul between New York or Halifax and Europe as compared with Buenos Aires and Europe. This preference toward North America has held back automobile sales in grain-producing parts of South America, but the present prices show a return to the South American field.

ACCESSORIES In South America

Part V

Co-operative Selling Must Receive More Attention—European Competition Will Follow Close of War

By David Beecroft

¶ EDITOR'S NOTE:—This is the fifth of a series of articles embodying the close observations of automobile and general trade conditions in South America made by Mr. Beecroft, Directing Editor of THE AUTOMOBILE, *during a 10-weeks' trip through Argentina, Uruguay and Southern Brazil. As a delegate of the United States Government and member of the Argentine Return Visit Committee, Mr. Beecroft had exceptional opportunities to become intimately familiar with conditions in South America, and his articles bring out the salient points forcibly.*

CO-OPERATIVE selling of U. S. A. accessories in South America will have to receive more attention than it has in the past. It is too costly for a manufacturer of one accessory to open agencies in South America, but that one maker can combine with six, a dozen or a score of other makers. Such co-operative selling would, in addition to reducing marketing cost, develop a highly-needed brotherly spirit among our U. S. A. manufacturers.

We must largely forget competition among ourselves and keep our eye on international competition. International competition is a new phrase, but it is a stern reality in South American business.

After the war unquestionably the allied nations will among themselves co-operate in every way possible. That program has already been indicated. Our tire makers instead of fighting among themselves for business will have to co-operate to meet the trade war of England, France and Italy.

It would be a good investment for our accessory and parts manufacturers to adopt general policies with regard to South American trade, supporting such policies as work for the general benefit of our goods. There will arise many broad programs of policy that have to be handled and different U. S. A. firms should be a unit in such. Such united action will give our entire accessory trade a status that cannot be otherwise obtained; without such our makers may exhaust their energies in trade strife among themselves.

We Must Reduce Prices

In the matter of prices and terms of payment this co-operation is essential. Some U. S. A. goods are being sold at too high prices. This is due to their being handled through exporters rather than by the manufacturers direct. As a result our goods are getting and already have a reputation for being high priced. Certain U. S. A. tire repairs are being used solely because the French goods cannot be obtained. The South American dealers know our prices are too high, but they must have the goods. After the war they will go back to European goods just as fast as they can unless we change our policy.

There is a chance, a good fighting chance, that we can hold this trade providing we put our prices at once where they should be. It is short-sighted policy in building up an export trade to exact high prices to-day simply because you can get them, only to lose the trade to-morrow when international competition is renewed. Our makers can arrive at better understandings in the question of price by co-operation, getting together and going into South America with a united U. S. A. price situation.

One of the greatest factors in international trade that we will find of importance in South America is the reputation of our U. S. A. goods. Every firm that gets a bad reputation hurts the entire U. S. A. business. If U. S. A. accessories have a good reputation, then it will be easy to do business there. If our goods have a poor reputation, it makes it harder for every concern to enter that market.

Enter the Market Directly

There are many U. S. A. lines of accessories on the Argentine and Brazilian markets that are not trade marked goods. There is no manufacturer's name attached to them. The goods are not always reliable. There is often no service connected with them. Often the goods do not arrive in good condition. Sometimes they never function as they are intended to. The net result is a general discredit to our goods.

This has happened in scores of cases. A few examples will suffice: We have told of the shipment of defective hand horns, of poor lubricating oil, of cheap polishes for bodies and metals, and we could cite many others. Not a single one of these lines was trade marked. The Argentine did not know who made them. To him they were U. S. A. goods and you could scarcely blame him for gaging all of our accessories on their plane. We would do the same thing. This must be avoided. How?

The quickest and best way to overcome this deplorable situation is for our makers to enter the market directly. We must let the South American people know who are our big reliable markets. We must let them know that we make goods to which we are not ashamed to attach our names. We must let them know the good brands we manufacture. We must let them know that these non-trade marked goods are our poorest lines, not our good lines—let them know that we

have a big army of accessory makers of high business caliber.

We must go further: Often some of our best U. S. A. lines are poorly handled in Argentina and Brazil, although they are excellently handled in U. S. A. This is generally due to the goods being shipped abroad through exporters. Naturally the exporter has not the same single interest in any accessory that the maker has. To the exporter any accessory is only one of hundreds of different lines he exports. The exporter does not understand the line the same as the maker. Often the exporter ships goods not well suited to the needs, and naturally the reputation of U. S. A. goods suffers. Here is an example:

A large Brazilian automobile dealer, to get the agency for a certain Detroit make of automobile cabled his exporter in New York to ship him five or six cars. If they turned out well he would secure the agency. The exporting house shipped a couple of coupés, one sedan type, a runabout and a touring car. The only model that was of any use was the touring car. There was no demand for coupés or sedans. There was no demand for runabouts. The demand was only for touring cars. The net result was that the dealer did not close the agency. He blamed our maker for the shortcoming of the exporter. Our international reputation suffered. Search revealed the fact that the exporter got a special price on the lot.

Here is an example from the accessory field: A supply house wanted hand horns, and the exporter shipped electric motor horns. The electric horns were no good without batteries, but as the supply house wanted to sell the horns for European cars using gas lighting, the motor-driven horns were no good. Here again our international reputation suffered and it always will suffer so long as our business is done through third parties who are not close enough to the needs of the industry to know best what line of goods is best suited for the case. It is for this reason that our makers must give the matter more attention.

What is true in South America in this accessory matter also applies to Australia and South Africa. Recently we talked to some of the largest dealers from Australia and South Africa and they both told us the same story. Our makers have a notoriously bad reputation as exporters. We are the laughing-stock of the world. Too many of our makers have no conception of the magnitude of foreign business. Here are two examples given in the last few weeks:

Foreign Trade Underestimated

One of our manufacturers sold the entire right of selling his accessory in all British South Africa for one trifling order of $120. This represented just twenty of the accessories in question. The South African jobber cabled for an order of several thousand within 3 months. The original order of twenty were sold in less than a week. Here our manufacturer gave away a good business investment, because he had no conception of the field.

Another example of similar bad business was where the sole right for an accessory was sold for $160 for an entire continent.

Both of these examples represent the other extreme, but they go to show what a poor grasp we have of the exporting business.

Some of our largest accessory makers in U. S. A. are not in any of the foreign markets direct, but are having their lines handled through exporters. In some cases these goods have a very unsavory reputation. In the words of one large foreign jobber, "some of your goods literally stink because of the way in which they are handled abroad." This foreign jobber mentioned half a dozen lines of accessories that are not getting established abroad for this reason. Here in U. S. A. they are our biggest firms.

As accessory makers we will have to do the same as older business concerns have done, namely, establish our own agencies direct or open our own branches. We have accessory houses that are larger than many old established lines controlling their own foreign business. Look at some of these that have their own arrangements and who are literally saving our U. S. A. reputation abroad.

Fairbanks Morse, Singer Sewing Machine, National Cash Register, Remington typewriter, Underwood typewriter, International Harvester, General Electric, Westinghouse, U. S. Steel Products Co., Corbin Screw Corp. and many others are our trade stalwarts in South America. They have found it worth while to send their best men there. These firms have not only built up a reputation, but they have spent millions to establish what standing we have as international traders.

Must Do Our Share

The automobile industry is duty bound to give these firms its support. There is no question but that we will be strong in that market, but we must carry our due share of the load. Bowser has an agency for its tanks in Argentina and already has established itself in the market. A few of our makers of dry cells have Argentine agencies and nothing but favorable comments are heard regarding their business arrangements. Our largest tire makers are establishing themselves in first-class manner, and they merit credit for what they have done. But there are too many of our accessory people who have not awakened to the situation.

Wider Representation Needed

We have not to-day a wide enough representation in such lines of accessories as speedometers, batteries, spark plugs, jacks, horns, polishes, bearings, vulcanizers, wrenches and other lines of tools. Many other lines can be added.

Before concluding this series on accessories there are a few other lines that should be included with those referred to in previous articles. There is a strong demand for top materials, providing they are cut for several of the best U. S. A. sellers. Tops wear out very quickly in Argentina and Brazil and the owner wants top materials all cut ready to be applied. This is true with regard to Ford, Overland, Studebaker, Hupmobile, Buick and a few other makes and will be true with regard to many more different makes within the next year or so.

Several of our magneto makers are already well established, Bosch and Splitdorf being represented. Eisemann has representation through France. Our concerns making electric starting and lighting apparatus are not strong. There is scarcely any carbureter representation, and as near as we could discover the European carbureter is much more firmly established than our own. Several of our own makes are scarcely known and some never heard of. With many of our cars selling in those countries there will be marked development in the carbureter possibilities. The same applies to rims, clocks, shock absorbers, and every line of accessory that is going to add to the utility of the car.

Manufacturers of raw materials will find a good market in Argentina, Brazil and other Latin-American nations. Every large supply house in addition to accessories carries a heavy stock of blanks from which spur and bevel gears of any size can be made.

There is a big supply of gaskets, assorted nuts and bolts, spring clips, bar and sheet steel stock, door hinges, door handles and, in short, everything needed in the automobile. Keep in mind that South American countries are not manufacturing nations, and so practically everything must be imported. The supply houses handle not only accessories, but raw materials as well. Often raw materials occupy as much space in a store as accessories.

In conclusion: The field is there. Let us possess it as it should be possessed.

Tractor Drives Knotty Problem

Advantages of Caterpillar, Two-Wheel and One-Wheel Drives Appear to Depend Upon Nature of Work—Difficulty of Choosing Best Place for Weight

By A. Ludlow Clayden

Left—Large Case tractor, showing the sort of treads used to give a grip on plowing land

Below—The "Happy Farmer," a tractor in which the weight is very little forward of the driving axle

¶ This is the third of a series of articles based on an intimate study of tractor requirements and the efforts of the tractor engineers to meet the problems in design and construction arising from the demands made upon the machines in active service. The author has been in close touch with the tractors and the manufacturers at the recent demonstrations, so that this series of articles accurately reflects the conditions discussed, besides giving a clearly defined idea of the principal trends in tractor engineering.

IN a previous article the writer touched upon some of the high spots in the design of engines for tractors, and H. L. Horning of the Waukeshaw Motor Co. has contributed much valuable detail information on the same subject in his recent S. A. E. paper, the third installment of which appears in this issue of THE AUTOMOBILE. A matter on which there is even more difference of opinion, and which is far more difficult to argue about is the best form of wheel or drive arrangement for tractor service.

At present we have almost all possible arrangements. One wheel with a pair of small wheels, one to steer and one to maintain balance sideways, is used by some manufacturers, this being called the drum type. Then we have two driving wheels with either one or two steering wheels that are supposed not to carry much of the weight. Then come true three-wheel and four-wheel machines with a fair proportion of the weight on the steering wheel or wheels, and finally, there is the track-laying type with the wheels inside an endless chain which is placed on the ground and rolled over by the wheels. There are also machines with a track-laying arrangement for the drive, and a wheel or wheels to steer and carry part of the weight.

The track-laying type is usually known as a caterpillar, although this particular phrase is claimed to be the property of one firm and so not available for general use. However, it is the term commonly employed and will therefore be used by the writer in dealing with all applications of this kind of drive.

It is unlikely that one form of drive is the best for all purposes; there are reasons which make different designs most suitable for different circumstances. For example, there is nothing to compare for a moment with the caterpillar for operation on very soft ground. The unit pressure is small and the tractive grip the maximum possible for the weight of the machine; so on peaty soil or sand or for hauling guns through wet dirt there is nothing which will compare with the caterpillar, yet for use on hard ground it has drawbacks which make the wheel design preferable.

However, to look at the fundamentals of the problem of choosing a drive, we have first the necessity for providing enough grip between the drive and the ground to prevent the slipping of the drive by the engine under any circumstances. The caterpillar offers the maximum traction having one surface in contact with the ground and all the weight upon it. The automobile offers the other end of vehicular range with

small surface and half the weight on it. Average tractor requirements are somewhere between these two extremes.

As a second requirement we need a drive, if we can get it, which will have a tread no wider than the strip of earth that can be plowed. If we can pull four plows, the drive ought not to be more than four plows wide, six plows and it can be half as wide again and so on.

Third, we want a direct pull for the plows, the center line of the drive should also be the center line of whatever the tractor is pulling, thus avoiding side draft, which is obviously wasteful of power.

Fourth, if we do not need the extreme limit of the caterpillar we still want sufficient area of contact on the ground to provide traction on moderately soft earth.

Fifth, we want ability to turn in a small circle, a very small circle, so as to facilitate maneuvering in confined spaces and to allow plowing to be carried as near as possible to the limits of the field.

Drawbacks of Caterpillar

Before passing on to the consideration of wheeled machines, the drawbacks of the caterpillar type may be mentioned, because this is the ideal for traction per pound of weight and for maneuvering, because by going ahead on one tread chain and astern on the other it is possible almost to spin around the caterpillar in its own length.

The difficulties are mechanical. Obviously a steel chain must have links and links must have bearings. A steel chain to be efficient and to have long life ought to be inclosed in an oil bath; it most certainly ought not to be forcibly charged with mud and sand. Thus the work absorbed by the caterpillar tread is considerable, and the life of the chain is not all that could be desired. For steering we must drive one side more than another, so that directional control is somewhat complicated, and finally, the chain tread is rather expensive, and cannot well be cheapened if it is to last reasonably well in service.

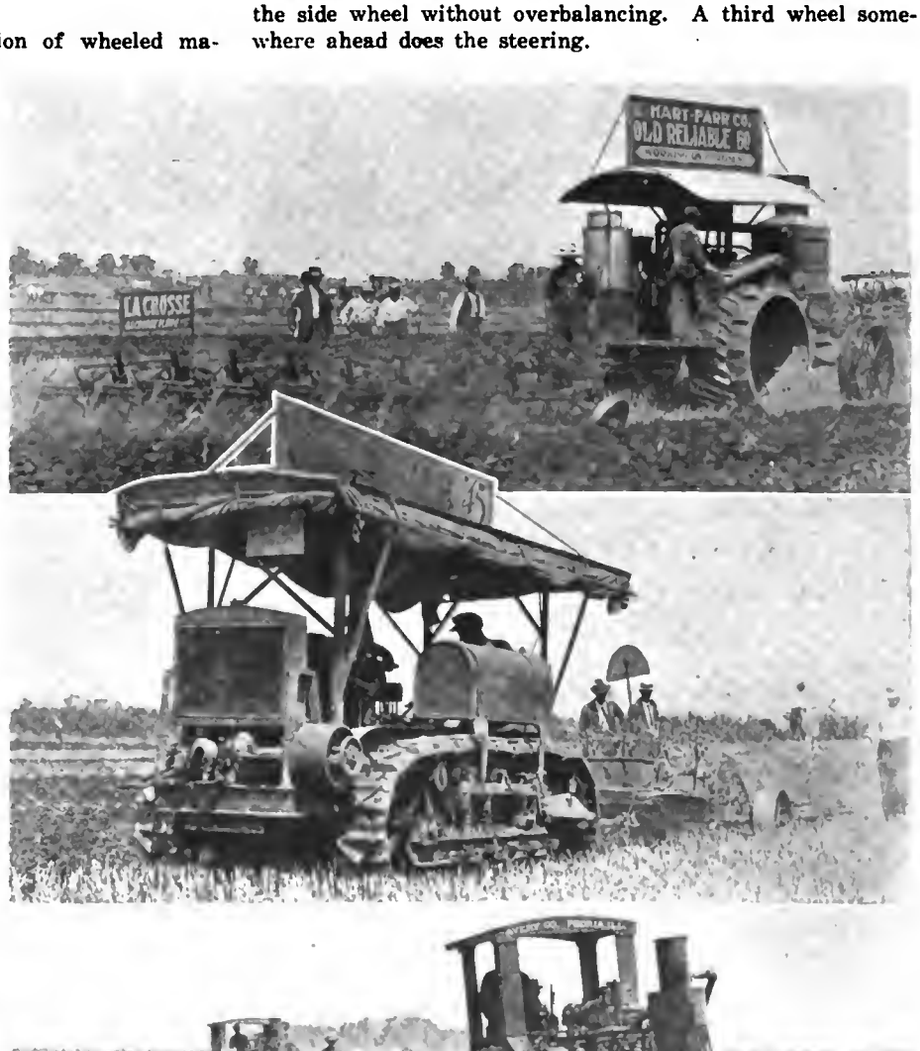
This is not an indictment of the caterpillar, it is merely a brief summary of its drawbacks. It is probable that means could be devised for rendering the bearings in the chain tread perfectly dirt-proof and thus increasing the efficiency and the life of the chain. Really the caterpillar seems to be a particularly promising type of machine which will develop into something far better than it is to-day. Numbers of the machines are being used where they are the only thing that possibly could do the work, and the experience gained will be valuable in bettering the design. Thus it is hardly possible properly to fix the place of the caterpillar in the tractor world at present; it will not be possible for some time to come, it may even be 10 years before the type is developed fully.

There is another sort of machine using a caterpillar drive in conjunction with wheels. In this a small chain tread assembly with two wheels is located suitably for driving and the weight is balanced, partly supported and steered by wheels. This system gets away from the complicated steering of the full caterpillar and provides a good driving grip without the use of a very large and wide driving wheel or wheels. The chain being smaller is less costly to renew when worn out, so that this design may possibly develop along with the full caterpillar.

A possible trouble with a large and powerful tractor might be to get enough weight balanced on the tread; in other words, there may be a limit of size where the caterpillar drive with wheels for steering would be no better than an all-wheeled machine on traction and general convenience.

Drum Suits Small Power

In the drum type of tractor there is one large wheel with the engine and gearing located as close as possible to one side of the wheel. There is then a smaller side wheel which does no driving, but carries a little of the weight, just enough to allow the tractor to lean over in the direction away from the side wheel without overbalancing. A third wheel somewhere ahead does the steering.



Upper—A large tractor hauling eight plows wider than itself. The extension pieces on the wheels to give support for the weight in soft going should be observed

Middle—The Holt caterpillar with weight distributed evenly over the whole tread of the chain

Lower—The big Avery in the foreground has the weight well in front of the driving axle of the machine

Upper—The Bates Steel Mule has a caterpillar rear drive and the two front wheels are for balancing the weight and steering. Only a part of the weight is on the driving member, yet the traction is sufficient for all purposes

Lower—An example of the drum type where the drive is taken through a single large wheel, the weight being balanced by a side wheel and partly supported by a front wheel which does the steering

The advantages of this design for small power is that the one big wheel does not need to be wider than the strip that is covered by the plows the machine can pull, which means that no driving wheel has to run on ground already plowed. Against this advantage may be balanced the drawback noticeable in drawing harrows or other cultivating machines, for then the drum packs the earth in strips a few yards apart and the light dragging of the wide machine being towed is not enough to unpack the soil. This, however, is also true of all other types of tractor, and the packing caused by a drum is no worse than that caused by two wheel drives if the unit pressure is the same.

Another advantage of the drum type is that there is no need for a differential, there is no rear axle in the ordinary sense and the engine and gearing can be arranged compactly. Also, not being between two big wheels, the power-plant can be very accessible and yet have the bulk of its weight concentrated on the driving surface.

Required Driving Pressure

Before proceeding with this analysis of drives, it may be well to mention the amount of unit pressure required to give the requisite tractive effort. At present this must remain something of a guess, it is not possible to say that it must be just so many pounds per square inch. However, it is a fairly safe rough and ready rule, with wheeled drives, to say that the weight must be equal to the tractive effort.

In considering tractor engine requirements it was suggested that at least 1000-lb. drawbar per plow was necessary, so this means for each plow pulled the weight on the driving wheels should be 1000 lb. Some engineers think this amount too much, others say it is too little, and this again is a matter that experience must decide.

However, whether we accept the 1000 lb. or not, this does not help to settle the proper width of wheel. The traction depends upon the pressure, not upon the area, so a large area with small unit pressure has just the same tractive ability as a small area with higher unit pressure, as long as the nature of the surfaces in contact is the same. What is necessary is to have the wheels so wide that they will not sink into soft earth nor have too powerful a packing action on freshly plowed soil, which means they should be as large as possible. Against large size is weight, for the big wheels are not light and there is everything to lose and nothing to gain by making the total weight on the drivers more than that required to give traction enough for the plows.

Of course, the co-efficient of friction between the wheel and the earth is very high, and it is customary to increase it greatly by putting studs in the treads or bars across them. There is no difficulty in using high unit pressures and small wheels on dry earth, but a small wheel will soon dig itself in on soft going. Here we see the advantage of large diameter as compared with great width, for the big wheel will roll out of a deep hole that might engulf a smaller one. Getting a tractor weighing 4 or 5 tons out of a hole in a soft field is somewhat of an undertaking if another machine is not on hand to do some towing.

Really for wheel diameter and width little more can be done than to refer to current practice and then experiment, but a good deal can be done in utilizing the weight of the engine and transmission to better advantage. In the diagram, Fig. 1, suppose that the driving wheel has a center O and that the drawbar pull P is applied at radius r. Then, if there were no other wheels, but the power plant had all of its weight on the one axle O, obviously it would have to be located back of the axle with the center of gravity at W, so that $Wr1 = Pr$.

If the weight is further forward and there is a front wheel to support part of it, the effect of the P is to throw a reactive pressure on the front wheel. In Fig. 2 obviously $Pr + Wr1$ must equal $pr2$ where $r2$ is equal to the wheelbase of the machine. In Fig. 3 we have the steering wheel behind, and then the effect of the pull P is to lift the rear wheel; when $Pr = Wr1$ then $p = O$.

We can thus say that we are utilizing the weight best when it is back of the driving axle, but if it is in this position it must be a good way back so as to maintain enough pressure on the steering wheel to give a grip and prevent the wheel from being lifted off the ground. Even then striking a stump might cause the whole mass of the tractor to revolve around the axle.

If the weight is in front it is not being utilized to best advantage, but we have safety and can be sure of steering grip. If the weight were right over the rear axle so that it was balanced there with no drawbar pull, we should have the condition of $r1$ equaling O which is the best compromise. Here again it must not be completely balanced or there will be no steering grip when the tractor is running by itself and no stability to prevent it turning backward around the axle should the front wheel strike a bump. Therefore the conclusion reached is that the best place for the center of gravity of the engine, transmission, etc., is just sufficiently forward of the driving axle to give steering on the front wheel.

From this elementary bit of mechanics it is possible to see where the caterpllar scores with its small wheels, for small wheel diameter means that the radius r is also very small. If we could get r down to O, the pull P does not disturb the balance of the weight in the slightest. It also follows that

the larger the wheel the more difficult it is to find the best place for the center of gravity, to suit all conditions and without wasting weight that might be utilized in obtaining tractive effort. There appears to be something in favor of a four-wheel layout with two driving wheels and two steering wheels, one in front and one behind. Here the weight could be poised so as to have the best effect at the maximum drawbar, and one or other of the small wheels would balance the machine under other conditions. There is no doubt, though, that three or four wheels with the steering in front and the center of gravity a little forward of the driving axle makes a quite satisfactory compromise.

In practice there is a very great deal of variation, and it is impossible to escape the conclusion that not all tractor engineers have given this question of weight distribution the attention it deserves. As long as there is enough weight for driving and steering every additional pound is dead weight, costing many dollars a year to carry about and something in first cost. In most cases the wheel size necessary will force the wheels to be fairly heavy in themselves and the rest of the machine should only add just enough more weight to bring the total up to the amount of the maximum drawbar the machine can exert.

Turning to a matter of detail, it is noteworthy that the suspension form of wheel is greatly used for tractors, though the tangent spoke principle has apparently been neglected. If a wheel is to be a tension wheel it can be built lighter for the same strength if it is on the tangential spoke principle.

Improving Wheel Tread

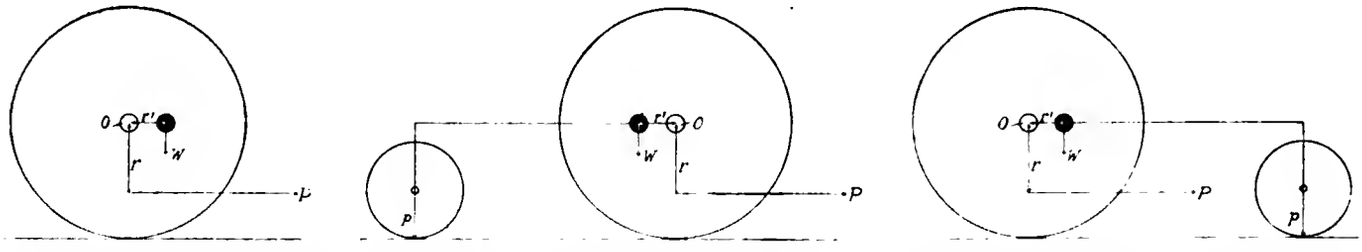
A wheel detail that seems capable of improvement is the method adopted for attaching the bars or studs to give traction on softish dirt. If tractors with studded wheels are run on macadam or other hard roads the destruction caused will be indescribable, yet the farmer wants to be able to use his tractor on road or farm. Thus it ought to be easy to change from the field tread to a smooth tread quickly. Many tractors have angle iron tread bars about 12 in. apart all around the driving wheels, each being attached by two or three bolts and nuts, to remove which would be three hours' work or more for one man. Similarly the studs often employed are each fixed individually. There ought to be some way of applying the whole rough tread for field work in two or three sections per wheel, so that the tread could be put on or removed in minutes instead of hours. There is no great mechanical difficulty to be overcome and such provision would meet the road destruction question before it actually arises; surely this is well worth while.

A way of fitting a rough tread which suggested itself to the writer and seems to have some possibilities, would be to make the tread in sections say a foot long, the sections being linked together by hinge pins so that the whole tread made a kind of chain. This could be laid on the ground flat and the tractor driven onto it, then the ends could be lifted up and the tread tightened on the wheel by some sort of turnbuckle which would cause it to grip. Probably some driving catches or dowels would be necessary at several points on the tread, to prevent the wheel tending to turn within it. Even if this suggestion is not practical, and very likely it is not, there ought to be some equally simple method that could be developed.

A typical four-wheel tractor with the weight well forward of the driving axle

At present all the two-wheel drive machines have a differential, and they could not be operated without one, but there is a prevalent opinion that a differential lock is an essential attachment, and that few tractors will be made without this in the future. Considerable interest is being taken by tractor men in the various differential gears that have recently come to the front and have the power to prevent the spinning of a wheel that loses traction. If one of these works out satisfactorily in tractor service it can have the whole tractor market, and the makers of such differentials would probably find it well worth while to make a special bid for this large and growing field.

Automatic steering has been sought on a good many of the small tractors, the idea being to allow the driver to relinquish the wheel in order to attend to his plows. Steering in such case is effected by a small wheel that runs in the furrow, while plowing, and has a link connecting to the steering gear at some convenient point. In the field these devices appear to operate very well indeed, and, even if two men are working together, there is no object in compelling one of them to hold the steering all the time if that is not really necessary. The additional amount of mechanism is small, the cost negligible and the added weight also too small to be of any account, so there is no obvious reason why automatic steering should not be used even more extensively than it is. Of course, it is more readily applicable to a small machine where the amount of force needed for steering is small than to a big machine.



Left—Fig. 1—With a driving wheel center O and drawbar pull P applied at radius r, all the weight of the power plant being on the one axle, the center of gravity would have to be behind the axle at W. Center—Fig. 2—With the weight farther forward and partly supported by a front wheel the pull P throws a reactive pressure on the front wheel. Right—Fig. 3—With the steering wheel behind pull P tends to lift the rear wheel

Temperature Control Will Be Elaborate

Need for Different Temperatures in Different Parts of Automobile Engines Will Lead to Many Automatic Devices is Opinion of Detroit Meeting

C. F. KETTERING, the man who held the rapt attention of the S. A. E. for a whole evening while he lectured on scientific matters on the Noronic last June, started a wonderfully interesting discussion at the opening meeting of the Detroit section of the S. A. E. on Sept. 14. He read no paper, nor did he speak from notes, but simply talked for an hour on the problems of temperature control in automobile engines, citing the difficulties and hinting the methods by which they may possibly be surmounted.

The conclusions reached after the lecture and the discussion were that heavy gasoline would compel temperature control on automobile engines, and that such control would probably extend beyond that of the water temperature alone. Engineers were started along the line of thought required to bring definite results, and a whole field of necessary investigation was opened up.

The conclusions were indefinite, that is to say no participator in the discussion could say just what ought to be the temperatures of different parts of an engine; perhaps the most immediately interesting part of the proceedings were the remarks made regarding the problem of starting from cold, C. F. Kettering suggesting the use of electricity and Howard Marmon the employment of a burner or pilot light to bring the carbureter and cylinders up to proper operating condition. The drawbacks of over heating were given attention as much as those of under heating and it is safe to say that hardly a man of the large roomful present but went away with his mind set on a problem he had so far considered in only a cursory sort of a way.

Heat for Vaporization

Kettering began by pointing out that a certain amount of heat is necessary for vaporizing any liquid fuel, that an engine burning so many gallons of gasoline per hour requires so much heat to be taken from somewhere in order to vaporize that gasoline; a perfectly definite quantity independent of anything else.

Kerosene requires more heat than gasoline, of course, but the amount needed is still constant for a given bulk of fuel. With light gasoline, like we used to have, the heat could be taken from the atmosphere over a wide range of air temperatures. But this is no longer the case. We must get extra heat from somewhere. Electricity, the ideal form of energy for easy control, was out of the question, far too much heat is required to vaporize heavy gasolines. Also we are now wasting about 50 per cent of the total thermal value of fuel in the cooling water and another 40 per cent in the exhaust gas, so we have only 10 per cent left and do not want to use any of this for vaporizing the fuel. We may either take from the waste heat of the water or of the exhaust for that purpose.

Later on in his discourse Kettering mentioned that electrically derived heat might be used for heating up a carbureter previous to staring, that is, before exhaust heat was available.

Ill Effects of Condensation

There are bad effects through not heating the intake gases sufficiently, effects that may cause actual damage to the engine. In a heavy gasoline, such as is being sold to-day, there are still some light fractions, added to bring down the gravity of the whole. In starting, or in running with an intake that is too cold, these light fractions are vaporized by the heat of compression and burnt out of the gas mixture during combustion, leaving the heavy fractions partially unconsumed.

This action causes a condensation or deposit of heavy kerosene which dissolves in the lubricating oil, thinning it and reducing its lubricating properties, and long continued running with this action going on will certainly cause cylinder and bearing wear. (This has been found to be particularly true with tractors running on kerosene, and for such machines it is recommended that all the oil in the engine be thrown away after 10 or 15 hr. running.)

Running on Half Throttle

A similar effect is obtained by running on half throttle, as most cars are driven most of the time. The depression in the intake caused by the throttling causes wet deposits of fuel to be made in the intake passage; these get into the cylinder and the evil effects of the heavy fractions are noticed. The only way to prevent this condensation is so to heat the manifold that it will supply enough heat to the fuel to keep it in gaseous form. The fuel must not only be made into a gas while in the carbureter, but must be kept in gaseous form while passing through the manifold into the engine.

Granting that once the engine was well warmed up it would run on quite heavy fuel, as long as proper heat for vaporization was supplied, Kettering turned to the problem of what constituted a fuel on which a start could be made from cold. He stated that, at normal air temperature, a fuel consisting of 1 qt. of 60 Baumé gasoline mixed in 5 gal. of 46 to 47 Baumé kerosene would enable starting to be performed, the light fraction doing all the work till heat was available to warm the carbureter and manifold. Such a mixture is just about the equivalent of 54 Baumé gasoline.

A method of supplying heat that has been tried and may have some usefulness is to warm the bowl of the carbureter, heating the fuel till its specific gravity is reduced to the desired Baumé. This, however, is not the equivalent of supplying heated air, as the warmed fuel can only hold enough heat to provide a small portion of what is required for total vaporization. Thus we want hot air, but not too hot because by decreasing the density of the air we reduce the weight of air and fuel that the cylinder can draw in, and so cut down the power possibilities of the engine.

Water Heat Insufficient

To get proper vaporization under all circumstances with heavy fuel it is not enough to control the temperature of the water in the cylinder jackets. It will be necessary to control the temperature of the fuel itself and also of the air entering the carbureter, if we are to get ideal results. The kind of thermostat now being employed for water control is very powerful, though small in size it can exert considerable pressures and could be used for operating all sorts of mechanisms, so there ought to be no very great mechanical difficulties in the way.

The use of a mechanism to control water temperature for

internal combustion engines is not new, as long ago as 1885 a device had been patented for use on stationary gas engines which had as its purpose the maintenance of a constant jacket temperature. Other inventors had followed, the designs growing simpler and more effective, so it is rather remarkable that it is only recently that any attention has been given to this matter in the automobile field.

J. G. Vincent, Packard Motor Car Co., opened the discussion by saying that he had 2 years' experience of thermostatic control of cooling water and his work had shown him that there were slight differences in effect, according to where the thermostatic valve was placed. With the thermostat at the bottom of the water system it controls the temperature of the water entering the cylinders, but when placed at the top of the radiator it controls the temperature of the water leaving the engine jacket. While there might seem to be little difference, there is really a good deal.

Under normal operating conditions the amount of difference is small, but in cold weather the engine with the thermostat controlling the outlet from the cylinders where the water goes into the radiator, there is a considerable difference in the time taken to warm up the cylinders to proper working temperature.

Thermostat Operation

With the bottom position for the valve and thermostat it was set to close at 115 deg., and to open at 125, keeping the water at the bottom of the engine jackets at about 120 deg. What will then be the temperature of the water as it leaves the jackets at the top is variable, depending upon the weather.

On the other hand, if the thermostat and valve are at the top, so that the valve controls the outflow from the engine, then it would be set to open at between 160 and 170 deg. Until this temperature is reached no water can escape from the jackets. As the water grows warmer it rises into the cylinder heads and is trapped there till such time as the thermostat opens the valve.

Thus with the thermostat at the top the temperature of the cylinder head cannot be less than the required amount, but when the control is at the bottom the water in the heads may be too cold. Furthermore, with the top position the water cannot get any hotter than the set point (160 to 170 deg.) while it may get too hot if we control the bottom part of the system.

The engine warms up much quicker with the valve at the top, and tests showed a Packard engine would come up to working heat in 1½ min. with zero atmosphere. Vincent called attention to the fact that the valve must be tight if it is to be of any use.

Radiator Shields Alternative

Several Detroit manufacturers are now trying out a device consisting of a number of shutters mounted in front of the radiator which can be closed or opened by the action of a thermostat. Mr. Lewis, the Detroit Motor Appliance Co., interested in this device, called attention to the fact that it nullified the effect upon the water in the radiator of varying wind conditions. He allowed that heating up after starting would be slower when the whole body of water has to be warmed but thought there were advantages in having the radiator kept automatically from becoming too cold. A. P. Brush, who spoke later, also pointed out that one desirable effect of a constantly warm radiator was to heat the air which the carbureter was taking in, and so utilize some of the heat wasted in the water for performing a desired function.

A. Ludlow Clayden, THE AUTOMOBILE, spoke concerning the effect upon the problem of intake gas velocities. In attempting to carburate heavy fuel we have only the atmospheric pressure of 14.7 lb. per square inch to drive the air past the nozzle and so atomize the fuel. As atomization becomes more difficult carbureter makers are cutting down the size of choke tube so as to increase the velocity past the nozzle, and this increases the depression in the manifold and so aggravates the trouble of condensation.

Gas Velocity a Factor

Particularly in using kerosene it is noticeable that we require more heat for the intake manifold at low throttle, when less is available, and less heat at high throttle, because the tendency to recondense after atomization is increased as the depression in the manifold is made greater. It would therefore seem that there might be good reasons for controlling the amount of heat given to the manifold in proportion to the speed of the gas passing the carbureter nozzle.

He added that electricity seemed to be the ideal energy supply for warming up for starting purposes, and asked Mr. Kettering if the amount needed to warm the bowl of the carbureter sufficiently would be too heavy a demand on the battery. This question was afterwards answered to the effect that the current required would be some 30 amp. for about 2 min. duration and therefore not beyond a battery's capability.

F. O. Ball, Ball & Ball Carbureter Co., stated that he had made some inconclusive experiments with integral intake and exhaust manifolds and was continuing these in the endeavor to discover what the intake temperature ought to be.

K. W. Zimmerscheid, General Motors Co., said that we were always likely to forget that gasoline and air must be mixed by weight and not by volume and that when we heated either, so altering its specific gravity, we upset volumetric metering set for different temperatures. He considered 170 deg. the ideal water jacket temperature and thought 140 deg. about the right temperature for an intake manifold. In arranging for heating the air taken in, the fact that we had to start with cold air must not be forgotten. He considered the best temperature for the entering air would be 120 deg. The fuel ought to be kept at a constant temperature. If the carbureter were insulated from the cylinder block by some nonconducting material it would be easy to control its temperature by means of a thermostat, using an individual water jacket for the instrument. Possibly a carbureter maintained at 120 deg. and an intake manifold at 180 deg. would be correct.

It was also desirable to prevent the temperature of the oil from falling too low. There is always risk of getting water in oil through condensation of the products of combustion that get past the rings and pistons. Probably this water passes the pistons in the form of steam, and, if the crankcase is warm, it will not condense, perhaps, but will have a chance to escape through the breather.

Howard Marmon, Nordyke & Marmon Co., said that the starting trouble was one of the worst the industry had had to face. He found himself wondering whether the simplest solution of the difficulty would not be to use a blow torch or pilot burner playing on the manifold and carbureter to warm them up to working temperature. A. P. Brush, Brush Engineering Assn., who followed, mentioned that small quantities of light spirit would always be available, and it would be comparatively simple to use a small tank of good gasoline to start and warm up, switching over to the heavier fuel when the desired temperature had been attained.

Power of Thermostat

D. McCall White, Cadillac Motor Car Co., said that E. E. Sweet of his company began experiments in 1907, and it was his tests that led up to the adoption of the thermostat by the Cadillac company. He gave several tabulations showing the characteristics of the thermostatic unit they employed. The following table shows the amount of expansion at different temperatures:

Truck and Tractor Engines—Part III

Water Pumps and Engine Cooling—Governor Design a Difficult Problem But Essential—Engine Lubrication—Application of Tractor Engines—Liberal Allowances Necessary

By H. L. Horning
Engineer and General Manager Waukesha Motor Co.

¶EDITOR'S NOTE.—This is the concluding installment of the paper Mr. Horning read at the third quarterly meeting of the Midwest section of the Society of Automobile Engineers held in Milwaukee, Wis., Sept. 1. Previous installments illustrated the differences in the demands on engines for trucks and tractors, outlining some of the more serious problems the engineer has to face in meeting them.

COOLING passenger-car engines sometimes is a serious problem. Cooling is the greatest problem in tractor engines. There are so many variables that little reliable information can be given as to water circulation or radiator capacity. Each individual case seems to require its own treatment. A tractor may be sent to Alberta or to Texas, and the extreme conditions determine the radiator capacity as well as the water pump.

The following limits may serve as a rough rule for water pump capacity:

$$G = \frac{B.H.P.}{V} \qquad (5)$$

In which G = gal. per min. water pump discharge through outlet to waterjacket.

V= Variable depending on engine and radiator design. For poorly designed combination V = 3.5. For a very efficient design V = 4.5.

There are some tests being run by a well-known company on the capacity of different type radiators and fan designs for tractor service which will be available soon, and which will constitute the only complete information available.

Manifolds

The only change manifolds require for truck or tractor service is in the intake, which should be smaller than usual, due to the low maximum speeds of engines and to the poor quality of fuel. The following formula for truck or tractor intake manifolds on egines up to 5-in. bore results in gas velocities which give good results for engine speeds encountered in these services and are correct for the poor gasoline and kerosene service:

$$I = 0.3\ B \qquad (6)$$

in which I = core diameter of intake manifold. Exhaust manifolds outlet cores have diameter corresponding approximately with the following formula:

$$Ex = 0.5\ B \qquad (7)$$

Governors for Truck and Tractor Engines

Governors must be installed on trucks primarily to prevent them from racing. Truck users have found governors useful to maintain the maximum speed of the trucks so as to give the driver both hands and feet for driving on straightaway work. It has been found that constant-speed governors help to keep up the maximum speed of the truck or make a truck average more miles in a day.

Governors for tractors are constant-speed type and usually are of the flyball design, which act directly on the butterfly throttle.

By far the most satisfactory arrangement for governors is to build them into the engine and to have them lubricated by the engine lubricating system.

Time will not allow a discussion of governor design other than to say that it has been the most difficult phase of truck and tractor engines, with which the writer has had to contend, and yet the most essential. Experience indicates that the flyball type is the most practical and easily understood by the average user and any form of this should prove satisfactory if built with ample bearings and wearing parts. Experience is such as to indicate that the butterfly is the most difficult form to use while being the easiest to manufacture.

A paper before this Society on governor forms, in the writer's opinion, is the best that has been written.

Lubrication of Truck and Tractor Engines

Generally speaking, the difficulty in lubricating tractor engines efficiently is second only to lubrication of racing engines. They are operating between the speed of maximum torque and maximum economy, a range in which the greatest heating occurs, which is directly responsible for most failures in tractor lubrication. What is true of tractor engines under 50 hp. applies with equal weight to truck engines.

Lubricating systems for both services are no different than found in passenger-car service with the exception that greater care must be taken to insure an abundance of oil at all times and to see that the system is such that if one point fails other parts will contribute oil to prevent sudden failure, but not sufficient for extended service.

To illustrate, one engine is equipped with a lubricating system that is so designed that if one connecting-rod pocket fails to get its oil, the adjacent rods supply enough to spread the development of a knock over 2 days' time so that it can be heard and corrected before full failure. Most oiling systems fail so quickly at one point that there is no chance to catch the failure in time. Truck engine bearings fail for lack of proper oil and from the above cause. Successful lubrication of heavy-duty engines imposes two functions on the oil.

First, to make an oil film between wearing surfaces.

Second, to act as a conveyor of heat. As the duty of an engine increases it is hard to tell which is the most important. The writer thoroughly believes in the great benefit derived from a large quantity of oil washing the heat from the lower part of the cylinders and crankcase into the lower pan, where design should promote dissipation of this collected heat.

The importance of an abundant screen area for very thoroughly straining the oil becomes of great importance in heavy-duty work.

Geared oil pumps have been found to be the most satisfactory and dependable in service; the only points where they fail is in leakage of oil, both internal and external, and being not sufficiently large for the service.

Proper lubricating oil for heavy service seems to be one important insurance for long life.

The following general classification of oils manufactured by leading oil companies seems to fit the requirements and is given here rather than a scientific statement of oil characteristics. Oil companies produce oils graded as follows:

Light.
Medium.
Heavy.
Extra heavy.

Whereas most automobile engines will thrive on light oil, truck engines require medium and tractor engines require medium-heavy and extra-heavy. Truck engines run well in winter on light oil and operate best in summer on medium. Some tractor engines operate in winter, spring and fall on medium and in summer, heavy oil. These are the smaller tractor engines which do not have the piston clearance nor do they get as hot generally as the large engines which operate in winter, early fall and late spring on medium and summers on heavy or even extra-heavy.

In burning gasoline, engines do not usually get as hot as when burning distillate or kerosene. If an engine operates well at any one season on one grade or weight of oil while burning gasoline, it will operate better with a heavier oil burning kerosene. Full force-feed systems can use heavier grades of oils than splash systems.

There is still another reason for heavier grades of oils in tractor service or when burning kerosene which has been mentioned before under crankshaft specifications, namely the dilution of the crankcase oil due to loss of mixture past the rings. Two days' service using the same lubricating oil while burning either gasoline or kerosene will result in heavy dilution of the crankcase oil.

One instance comes to the writer's mind in which, after a day's run, there was a greater quantity of oil and kerosene in the case at the end of the day than in the morning. In gasoline engines the gasoline evaporates under the best conditions of operation, while kerosene remains. Ten days' service with kerosene without complete change of oil will bring the power of an engine down 20 per cent. In hot weather, the drop will be greater. Frequent renewal of oil or boiling off the lighter constituents before mixing with other oil helps considerably.

Fuel

The most serious problem at this time is the matter of fuel for truck and tractor engines.

The problem of burning so-called gasolines now sold is becoming very serious and the further the situation develops the greater necessity there is for starting on one fuel and running on another. This leads to the question of burning straight kerosene.

The writer has produced and put in service engines of the regular truck type for burning kerosene in tractor work, and probably has out 2600 kerosene-burning engines, some having run for 3 years. The following conclusions regarding kerosene burning can be drawn:

(1) In tractor service where the load range is within 50 per cent of full load, kerosene can be used with reasonable satisfaction by the use of properly proportioned combined intake and exhaust manifold, the starting to be made on gasoline.

(2) Under these conditions the loss in volumetric efficiency due to heating the intake charge results usually in a loss of 10 to 20 per cent in the maximum horsepower output, whether gasoline or kerosene is used.

(3) Where speed of engine increases, the necessity for heat in the intake decreases, while when speed decreases necessary heat in intake increases. At full speed and power output, very slight heating of intake will suffice.

(4) Trucks can be made to operate on kerosene by the means mentioned above. One truck has operated one season in a pea harvest on 6.4 gallons per mile on a 2-ton truck equipped with a 3¾ by 5¾ engine. On the same job with conditions as nearly identical as possible and in the same service, the truck made 7.75 gal. per mile on kerosene. On a run of 50 miles the same truck made 10 miles per gallon over city and country roads with gasoline while on kerosene it made 15.25 miles, both figures being for truck running half the distance with pay load and return empty. These figures were made in an attempt to produce the best performance and all figures are given to encourage the hope of progress along this line. The design and applications which were responsible for this performance are being put in commercial shape.

(5) The science and art of burning kerosene as indicated by experience and the results obtained in service are identical with the principles set forth in several papers by Prof. Lucke, and the writer takes pleasure in testifying to the correctness of both the scientific and practical conclusions contained in his papers.

(6) *Our experience is that a kerosene engine does not carbon any more than a gasoline;* in fact, stays cleaner than a gasoline engine if vaporization is only comparatively well done.

(7) Where kerosene is well vaporized so that the mixture reaching the cylinder is in a dry state, a kerosene engine with a correctly designed combustion chamber will not heat as much as a gasoline engine.

(8) Experience as to the function of various elements in burning any or all grades of fuel is expressed as follows:

The carbureter meters and atomizes the fuel.
The manifold must vaporize the mixture.
The combustion chamber burns it.

It will save many inventors much disappointment to know that of all the things mentioned above the carbureter is the most perfect for the work they have to do.

The manifolds are next in efficiency.

The engines in their present form are furthest from being able to perform their functions in attempting to burn kerosene.

The development of kerosene burning in engines of the prevalent types must start with the engine and end with the carbureter.

Application of Tractor Engines

While a definite knowledge of transmission and tractive resistance losses are necessary in order to make a rational design, engines are generally applied based on broad considerations. The average light tractor will show a draw-bar horsepower of 60 per cent of the brake horsepower of the engine. A poor tractor and design will deliver only 50 per cent, while the best never exceeds 70 per cent, and this figure is doubled by good authorities. The above performances are based on the tractor operating on good solid dirt footing.

Plows require a draw-bar pull from 300 lb. apiece to 1200 lb. This is for a 14-in. mold-board plow cutting 14 in. wide and 8 in. deep. An average would be 600 lb. per plow. The average day-in and day-out plowing is done at 2¼ m.p.h., which is practically 200 ft. per min. If, therefore, we solve for horsepower necessary to get

$$\text{Hp.} = \frac{600 \times 200}{33{,}000} = 3.6 \text{ Hp.} \qquad (8)$$

$$\text{or } \frac{3.6 \times 100}{60} = 6 \text{ brake Hp. average.} \qquad (9)$$

For average service it requires 6 brake hp. per plow or 1 hp. for every 100-lb. draw-bar pull at 2¼ m.p.h. Using the figures as given above, it will be easily seen that the maximum requires just twice the average and the minimum, one-half the average. Twelve brake hp. per plow for maximum plowing conditions would therefore be correct. A great many tractors are based on these figures, which are considered conservative. The most efficient tractor in the writer's

experience allows only 6 brake hp. per plow but can handle only 800 lb. draw-bar pull or 4800 lb. for six plows at 1.7 m.p.h. Where this tractor is operated in 1200 lb. soil, it immediately plows very shallow or drops down to four plows.

Allowing a brake M. E. P. of 85 lb. per sq. in. as a working pressure and a piston speed of 1000 ft. per min. as a high working average, and figuring a tractor speed of 200 ft. per min. we then have a ratio of 5-1 for piston speed to tractor speed and our equation for draw-bar pull figured from the bore would be as follows:

$$D.B. = \frac{0.7852\ B^2 \times M.E.P.\ Ps \times E}{100\ Ts} \qquad (10)$$

In which D.B. = Tractor draw-bar pull.
M.E.P. = Average working pressure on piston.
B = Bore of engine in inches.
Ps = Piston speed.
$E = \frac{\text{Tractive Hp.}}{\text{Brake Hp.}}$
Ts = Tractor speed in ft. per min.

This formula points out the desirability of high working pressure in the cylinder, higher piston speeds and the influence of tractor efficiency and design on the size of the engine. It also calls strong attention to the fact that the high tractor speeds mean great cylinder size.

Inserting in equation (10) the various values ascribed above we simply with E = 70 per cent to

$$B = \sqrt{\frac{D.B.}{234}} \qquad (11)$$

and with an efficiency of 60 per cent

$$B^2 = \sqrt{\frac{D.B.}{194}} \qquad (12)$$

We have seen that it requires 1200 lb. maximum draw-bar pull efficiency and design on the size of the engine. It also calls strong attention for each plow. If we desire to know the bore of a four-cylinder engine necessary to pull the plows under the average conditions at 2¼ m.p.h., we substitute the 1200 lb. value in the equation (11) as follows:

$$B = \sqrt{\frac{3600}{234}} = 3.9$$

with an efficiency of 60 per cent

$$B = \sqrt{\frac{3600}{194}} = 4.3$$

The most frequently used engine for a three-plow tractor has a 4.25-in. bore. Tractor engine speeds have been determined mostly by what experience has shown to give endurance. Investigation has proven that the bore seems to have quite an influence on speeds, as well as the development of the art. The following formula expresses the speed of tractor engines in terms of the bore:

$$S = \sqrt{\frac{3{,}000{,}000}{0.04545\ B^3}} \qquad (13)$$

In which S = Revolutions per minute.
3,000,000 = A variable depending on manufacturer or development of the art.
0.04545 = Constant.
B = Bore in inches.

The formula holds good for 3¼-in. bore to the very largest sizes, even 9-in.

It is obvious that the factor 3,000,000 cannot hold for all engines of any manufacture, but it gives merely an average.

Life of Engine Parts

The piston speed of 1000 ft. per min. is higher than the old line manufacturers use, their practice being to limit piston speed to 800 ft. per min. While this most certainly results in longer life it is doubtful if this low figure is necessary with the efficient engines of to-day. The piston speed does not in itself determine the life of the engine parts. The engine endurance is more dependent on the square of the r.p.m., weight of reciprocating parts and above all on the efficiency of cooling and lubrication.

Tractor Applicable to Stationary Work

Engines on tractors are used for stationary work, such as running a grain separator, etc. The following formula is derived from service conditions:

$$D = 17\ C \qquad (14)$$

in which D = Displacement of the engine in cubic inches.
C = Size of cylinder on separator.

This assumes power feeds and wind stacker, or what is known as modern attachments on the separator.

General Conclusions

Within the scope of a paper it would be impossible to go very deeply into the science of internal combustion engineering. What has been written has been merely the attempts to answer in a general way the common daily questions that an engineer is called on to answer.

The writer has come to look on the building of engines from the following standpoints:

1—To generate quickly and to utilize all the heat that is possible to produce power.
2—To eliminate the greater part of the heat so as not to interfere with practical working conditions of the structures.
3—To maintain lubrication, an art not generally understood, the development of which is but beginning, and yet the art that makes engines possible.
4—To produce an engine which will not tear itself to pieces, or, in other words, will endure its own stresses, both dynamic and thermal.
5—To make such liberal allowances in design that engines will operate in spite of their neglected upkeep.
6—To get more out of given displacement by increasing the working mean effective pressure and to improve the details, so higher engine speeds can be used without reducing the life of a motor or satisfactory service.

This constitutes ideal progress and is the only way progress can be made.

—

Temperature Control Will Be Elaborate

(*Continued from page* 479)

Temperature	Expansion
150 deg.	0.101 in.
160 deg.	0.202 in.
170 deg.	0.250 in.
175 deg.	0.250 in.
200 deg.	0.254 in.

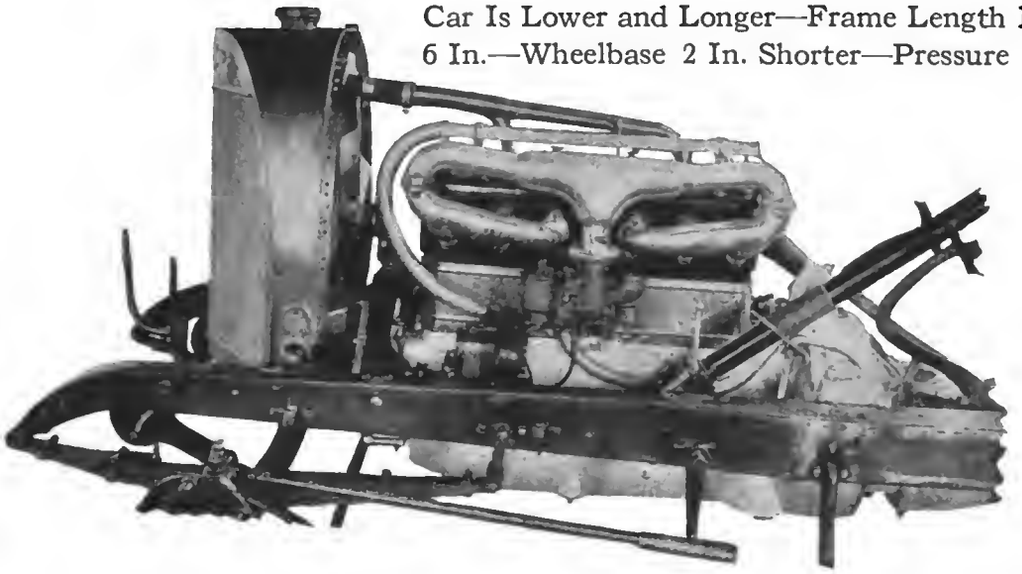
He said that he had tried running at boiling point and found the revolutions increased 150 per minute, while the power went up also, but piston expansion caused a drop again after a short period of running. Regarding the mechanical power of the thermostat unit it was as follows:

Temperature	Pressure Exerted, lb.
70 deg.	Closed
90 deg.	1
110 deg.	2.5
130 deg	3.5
170 deg.	9.5
190 deg.	14.5
190 deg.	21.0

Concerning the effect of the thermostat he tried taking a car from a room at 60 deg. and starting out in weather 8 deg. above. With the thermostat the carbureter was operating properly after 2.9 miles running with the water temperature in the jackets at 110. The same experiment was made without the thermostat and the carbureter was still popping back and misbehaving after 12 miles running.

Aluminum Alloy Pistons in Singer

Car Is Lower and Longer—Frame Length Increased 6 In.—Wheelbase 2 In. Shorter—Pressure Oil Feed



Intake side of the 4 by 5½-in. six-cylinder engine used in the new Singer

ALUMINUM alloy pistons are the most important innovation on the Singer six for 1917. This car, which sells for $3,500, is entering its third year of production with very few changes of a fundamental nature. There are, however, a number of detail improvements which have rendered the car, as a whole, lower, of slightly better characteristics at high speed, and more nearly perfect in suspension and control.

Car Is Longer and Lower

Magnalite has been selected as the material to supplant the cast-iron formerly used in the pistons. The only other engine change is in the oiling system, which heretofore has fed lubricant to the connecting-rod bearings by splash. In the new cars pressure feed, acting at 30 lb. per sq. in., sends the oil positively to the required spots. This has, of course, necessitated a new oil pump.

Structurally, the Singer car is longer and lower, although the wheelbase is shorter. This condition is obtained by an increase in the length of the frame of 6 in. The wheelbase is now 136 in., however, instead of 138 in., giving a greater over-all length on a shorter supporting span. The prime reason for the change in frame length is in a new type of gasoline tank which, instead of being cylindrical, is now of rectangular section. The cylindrical tank was used because it conformed to the turned-over frame-ends which formed the rear tire support. Since a spindle is now being mounted to carry two extra wire wheels, it is not necessary now to curve the frame over, and hence the new form of tank and longer frame.

This increase in frame length has effects which are not confined to the gasoline tank, in that more room has been secured in the body because of the extra supporting surface which is now possible beneath the sills. Not only is the body more roomy in a lengthwise direction, but the rear seat is also wider, having been increased from 45 in. to 47 in. The body is more comfortable also because of deeper upholstery, which is now 10 in., and, instead of tufting, French plating is used in its place. As far as decoration and conveniences go, the body is improved, particularly in the fitting of a mahogany case in the rear cowl behind the front seats.

Throughout the chassis there are several spots which have been improved in detail. The rear springs, for instance, are now flatter under load than they were formerly. In fact, with a fully loaded car springs should be horizontal, and the feature of this which is important to the driver is that the radius of oscillation of the spring is such that the results on the brake linkage are at a minimum; that is, there is no tendency to bind the brakes owing to spring oscillation because of the minimum projected length of the spring variation. The flatter springs, combined with lower bodies, make the entire car 3 in. lower than it was a year ago.

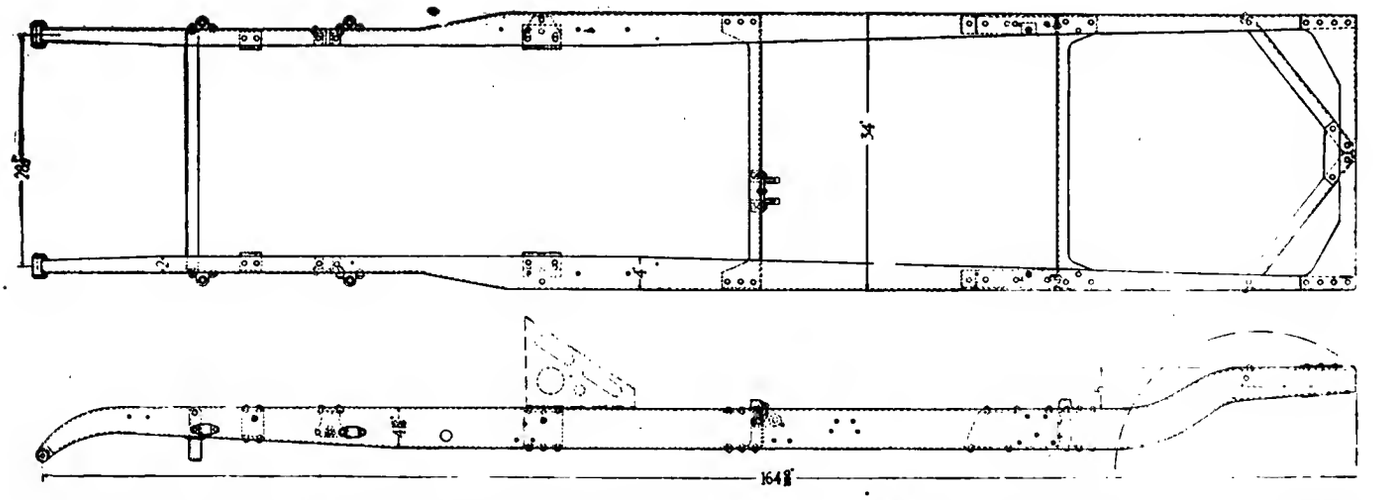
Front Spring Mounting Changed

In the front springs there has been an alteration in mounting. These are parallel to the center line of the car, but are tilted in their own vertical planes so that the forward end of the spring is lower than the rear. This has been done owing to the belief of the engineering department that the shocks are better absorbed in this way. The front spring horn has been made steadier and of greater bearing space to compensate for this change. In addition, the Timken axle, which is used in front, is now the heavy-duty design with full bearing support.

While the torque rod made up of welded Shelby tubing with cross members forming virtual webs is still employed, it is 8 in. shorter. This change has been accomplished by moving the front cross member which carries the support for the forward termination of the torque arm, back a corresponding distance. The result is that owing to the decreased length the torque rod is more rigid. Another change in the rear linkage is in the braking system which used to run continuously from the

Features of Singer Six

Engine	Six-Cylinder
Bore and Stroke	4 by 5½ in.
Formula Hp.	50
Oil Feed	Pressure
Clutch	Dry Plate
Gearset	Four-Speed
Wheelbase	136 in.
Electric System	Westinghouse
Upholstery	10 in.



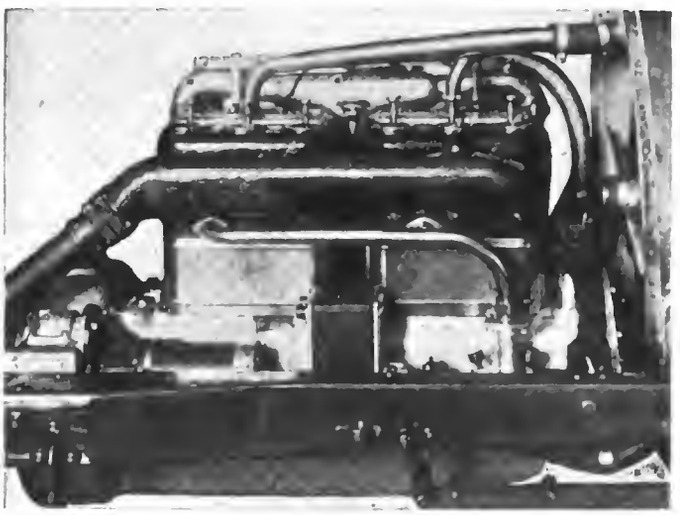
The Singer frame layout is very rigid, the 5-in. channels being well provided with cross members which stiffen it against racking stresses

operating levers back to the brakes. It has now been broken in two, giving a double reduction.

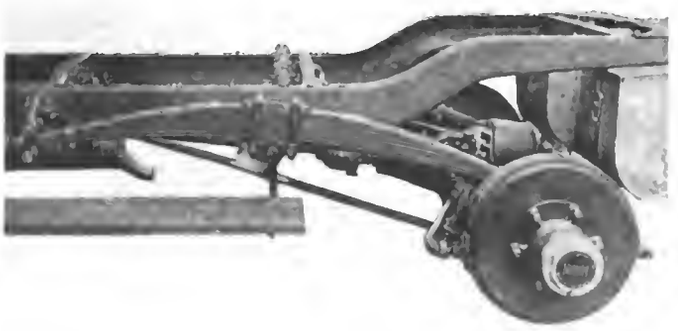
Clutch Easy to Operate

As regards control, the changes are only in detail. There is a longer clutch pedal which has increased the leverage to such an extent that a person standing beside the chassis has no trouble in disengaging the clutch with the hand. The steering gear has been changed and is now a Gemmer.

Fitted to the engine there are three attachments which are innovations for the 1917 model. These are a Rayfield carbureter, a Klaxon horn and a four-bladed cast aluminum fan.



Exhaust side of the engine used in the Singer six chassis



Cantilever rear spring on Singer chassis. This is flatter under load than previous models, making riding easier and also aiding in giving the car a low appearance

The carbureter formerly used was abandoned owing to its difficulty of adjustment, and the simpler Rayfield substituted. As with the other type, this is distinguished by its full hot-water and hot-air vaporizing means.

The Singer power plant is made up of a specially-built Herschell-Spillman engine, a dry plate clutch and a four-speed gearset with direct drive on fourth. While the engine is rated at 50 hp., it has developed in excess of 100 hp. at more than 2000 r. p. m., and with the aluminum alloy pistons there has been an increase in power output due to a higher maximum speed. Probably the most notable point of the power plant is the unique system of manifolding. It is to this that a large part of the power and flexibility is credited. The intake manifold has a sort of ram's horn effect, taking the gases from the carbureter, carrying them upward to the branches of a Y-shaped water-jacketed pipe, from where each branch divides into a loop to the three cylinders. This is clearly shown in the accompanying illustration of the intake side of the engine. While this manifold seems long, it will be noted that throughout a large part of its length it is heated, and, furthermore, it is of large diameter and has no sharp turns. It is stated that a marked gain in volumetric efficiency has been obtained due to this intake system.

Dual Exhaust Manifold

On the exhaust side there is a dual manifold in which each set of three cylinders is taken care of independently, thus avoiding conflicting or overlapping exhaust. The manifold itself is in one piece, but there is a wall between, which separates the flow from each block of three cylinders. The timing is arranged so that the exhaust of two cylinders are never open at the same time.

The engine dimensions are 4 by 5½. The cylinders are T-head, cast in threes, with integral waterjacket spaces closed by caps on the top. The manifolds are separate. The aluminum alloy pistons deliver the power to I-beam connecting-rods of forged steel. Both sets of valves are thoroughly inclosed, giving a clean exterior. The carbureter and magneto are mounted on the left, the latter being a Bosch high-tension instrument with the wire leads carried in conduits to the spark plugs. On the right side is mounted the electric generator and water pump, and also the starting motor. The generator and pump are carried on the same shaft, while the starting motor engages with the flywheel at the rear right of the engine.

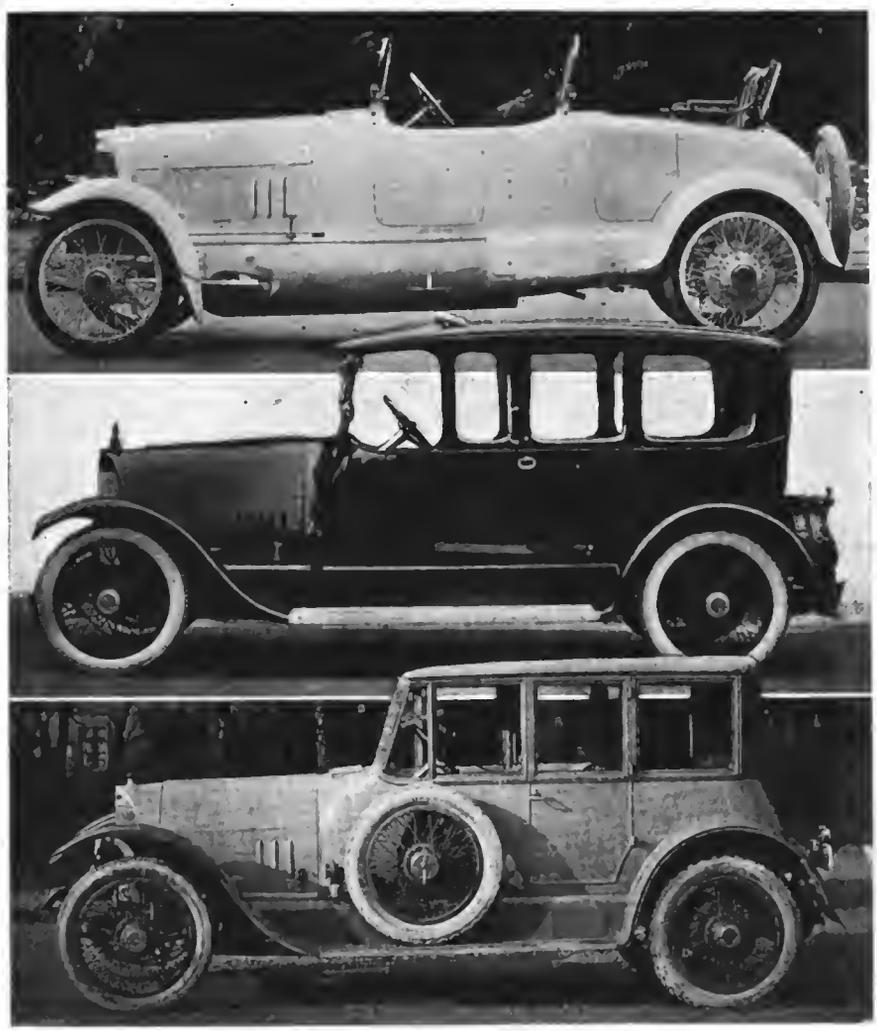
Besides the ignition system, the remainder of the electrical equipment is Westinghouse. There is a two-unit starting and lighting system operated on the single-wire system, and the storage battery is a Willard.

In the new oiling system the gear pump is driven off the

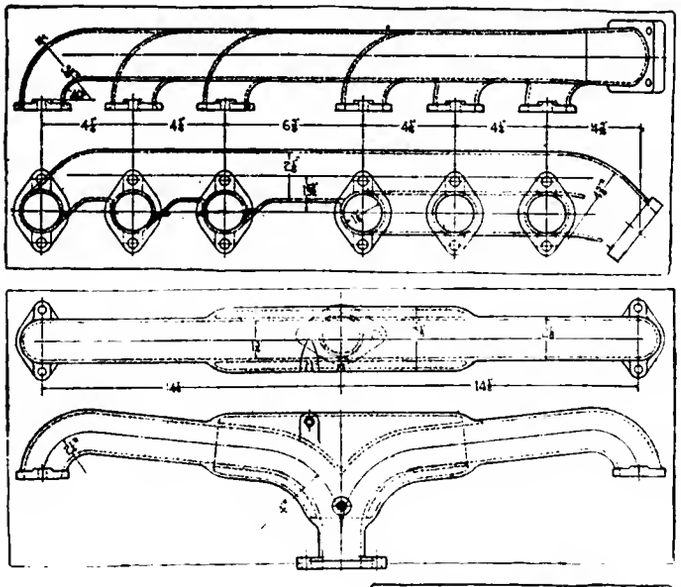
camshaft, and the oil reservoir is in the bottom of the crankcase. The oil is fed under pressure to the main bearings and through the hollow crankshaft to the remaining bearings under pressure. Under ordinary running the oil feed is up to 30 lb. per sq. in., but this will vary according to the work performed by the engine. The oil is recirculated and screened on its course through the lubricating system.

Power is transmitted from the motor to the gearset through a dry plate clutch consisting of steel disks faced with fiber. The clutch is held engaged by a double concentric helical spring, and although this spring is of sufficient strength to hold the car and to guard against slippage on acceleration, the disengagement can be affected by remarkably light pressure on the clutch pedal. This clutch is in a unit with the four-speed gearbox, which is featured by the mounting of the shafting on Timken roller bearings. The shifter mechanism is conventional with the lever mounted on the cover of the gearbox and operating on a ball joint.

Two Spicer universals are used in delivering the car to the rear axle, which is a Timken floating design. The drive is taken through the cantilever rear springs, but the torque is taken care of by a special member assembled and welded together in the triangular form of Shelby steel tubing. The rear axle gears are spiral bevel and provide a ratio on fourth speed or direct of 3½ to 1. The wheels are Houk wire and carry 35 by 5 in. tires, which have been continued owing to the remarkably good mileage experienced with this size.



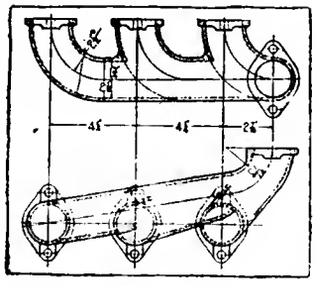
Illustrating some of the body styles mounted on the Singer chassis



Above — Exhaust manifold of Singer six, showing partition which separates the two cylinder sets

Below—Intake manifold, showing waterjackets

Right—Portion of intake manifold which bolts to cylinders



One of the noteworthy features of the Singer construction is in the rigidity of its frame layout. As is conventional practice, the individual members are of channel section with a 5-in. depth of web and 4-in. flanges. The frame is amply provided with cross members, which stiffen it against racking stresses. The cross members are fitted with large gusset plates which give them a capability of withstanding distorting tendencies.

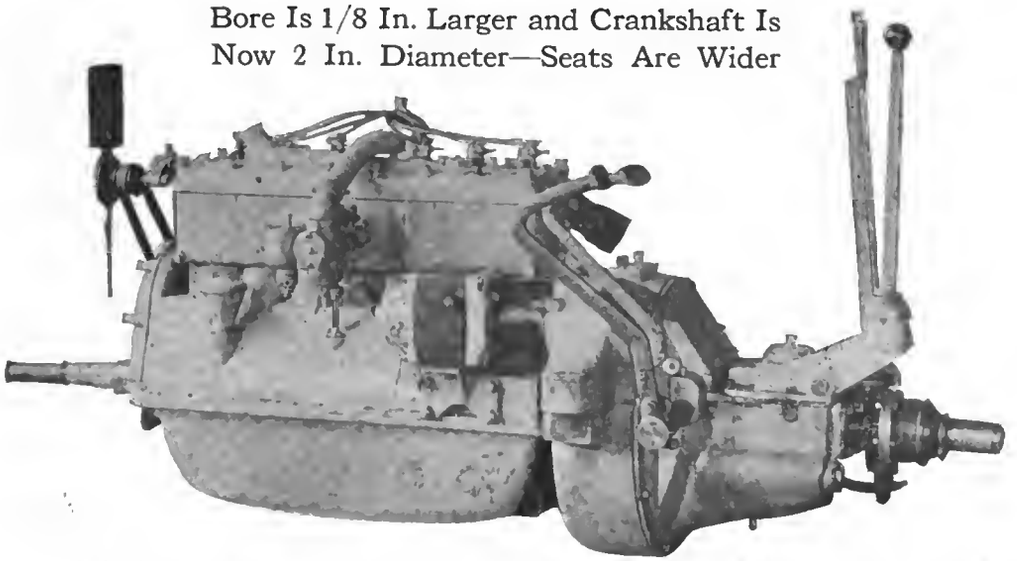
As would naturally be expected with a chassis of this price, the equipment is of the best. The radiator is a V-shape of exceptional size and capacity, and throughout the actual fittings are large and sturdy. The top is a one-man design provided with Jiffy side curtains, and connects with a special built-in ventilating windshield. The car also has a Warner 100-mile speedometer fitted with an electric light, Klaxon horn, 8-day keyless clock, electric trouble lamp with extension cord, tools, jack, power-driven tire pump, etc.

Standard Bodies Made

While the major percentage of bodies for the Singer cars are custom built, the concern is marketing standard roadster, touring and closed bodies. The standard touring design is a seven-passenger type with the Belgian double cowl. The extra seats fold into the backs of the front seats, and above them is located the mahogany cabinet which is an innovation this season. This is made of inlaid wood and is ornamental as well as of practical utility. Any color that is desired will be given the body, so that the purchaser is allowed a very wide latitude in making his selection. The chassis alone sells for $3,000.

New Glide Roomier and More Powerful

Bore Is 1/8 In. Larger and Crankshaft Is Now 2 In. Diameter—Seats Are Wider



Left side of the six-cylinder 3⅛ by 5-in. power plant used in the 1917 Glide, showing the mounting of the carbureter and the starting motor

NO changes of any consequence have been made in the Glide line for 1917. The light 6-40 car is continued with refinements and no additions have been made by the manufacturer, the Bartholomew Co., Peoria, Ill. In general, the changes which have been made in the car are such as to render it more powerful, more roomy and to increase the factor of safety. There have also been a few alterations which would tend toward making the car more nearly silent.

Probably the most notable change is in the engine where the bore has been increased from 3 to 3⅛ in. Another change in the engine is in the crankshaft which has been rendered more rigid by increasing the diameter to 2 in. instead of 1¾ in. Another change in the engine which would tend to make it noiseless is in the use of a Fabroil gear on the end of the camshaft.

While the mechanical changes noted have the most to do with the performance of the car it is also altered to some degree in appearance. One of the improvements is in the rounded cowl which takes away the square effect at the windshield and the latter is especially built to conform with the rounded shape of the cowl and fits exactly to its curvature.

As far as comfort features are concerned a conspicuous feature is the width of the rear seat which is now 47 in. and will accommodate three adults very comfortably. The springs have been lengthened both front and rear giving an easier suspension, the dimensions being now 38 and 54 in. respectively. In general, all the parts and accessory equipment made by specialists have been retained. This includes Westinghouse lighting and starting, Rayfield carbureter, Brown-Lipe three-speed gearset, Spicer universals, etc.

While only one chassis model is marketed the body line is quite complete as the car will be furnished in the regular touring models and with a detachable sedan top if desired. There is also a four-passenger close-coupled roadster in the process of production in which particular attention is stated by the makers to have been paid to the comfort of the occupants of the rear compartment. For instance, by a special arrangement of the footboard in the rear, the passengers have as much room with their feet as those in the front.

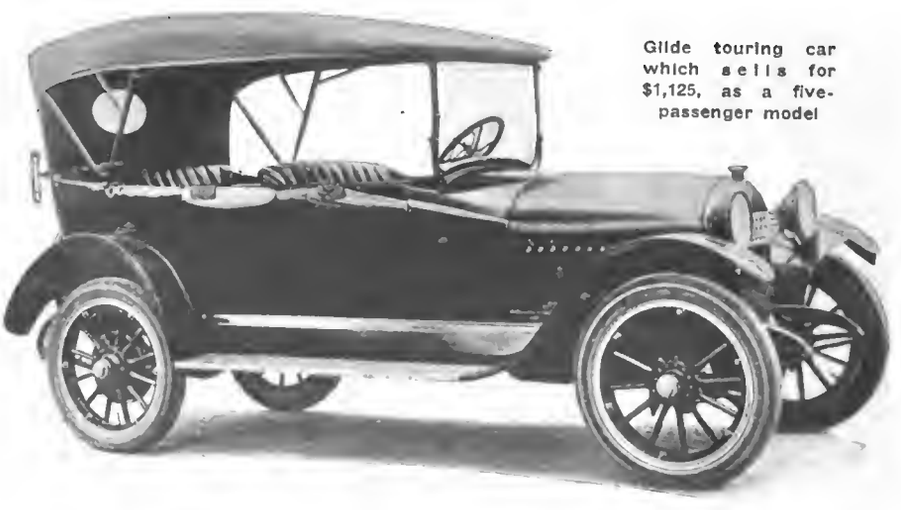
All the improvements in the body can really be summed up in the words, increased roominess. The 47-in. seat is 5 in. wider than in the 1916 car. The front seat is 1½ in. wider than previously. The windshield is 1¼ in. wider and 1½ in. higher besides the alteration in curving it to conform to the shape of the cowl. The top is also new, being a five-bow design with bare top holders and having the rear curtain fitted around the corners of the body to exclude dust. It is fastened to the back of the body by German silver molding.

A unit power plant is employed having block cylinders and three-point suspension. The six cylinders have a bore of 3⅛ and a stroke of 5 in. and are of L-head form with the valves on the right. This is a Rutenber product designed particularly for the Bartholomew company, and is known as model 25.

Three Piston Rings

The pistons are cast iron and are fitted with three separate rings. Two of these are close to the top and the third just beneath the wristpin boss. The wristpin is secured in the boss by a set screw and engages through a bronze bushing with the drop-forged I-beam connecting-rod.

The 2-in. crankshaft is a forging, as is also the camshaft which has a diameter of 1⅛ in. with the cams integral. The shafts are hardened and ground and are carried on plain bearings at the center and front and in an S. K. F. double row self-aligning bearing at the rear. Mushroom type flat



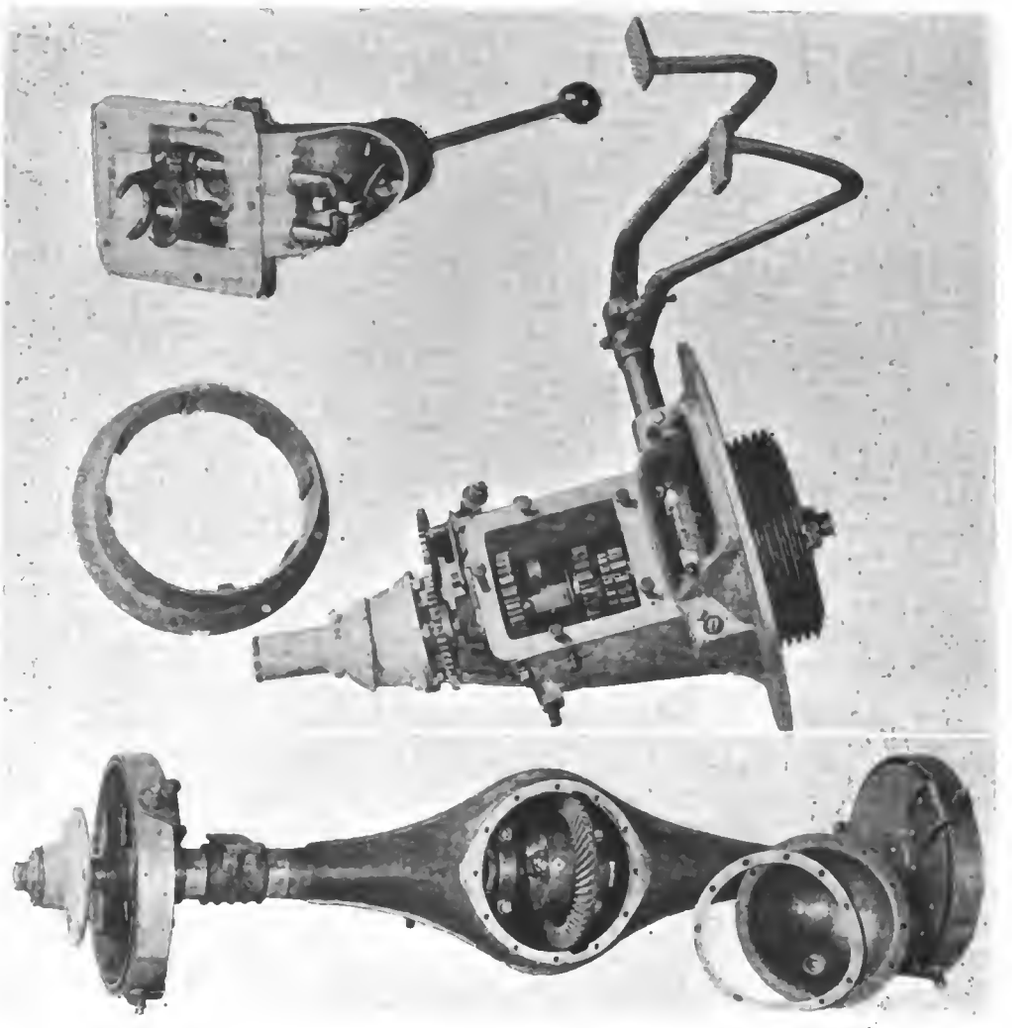
Glide touring car which sells for $1,125, as a five-passenger model

followers take the valve drive. These are offset 1/16 in. to distribute the wear. The valves are made in two parts with alloy steel stems and carbon steel heads. The diameter in the clear is 1 5/16 in. and the lift is 5/16. One of the features of the valve construction is that the brackets, together with the entire lifter mechanism, can be taken from the engine without disturbing the camshaft. This is done by removing the cover plate and stud nuts and then turning the starting crank until the valves are at their lowest level.

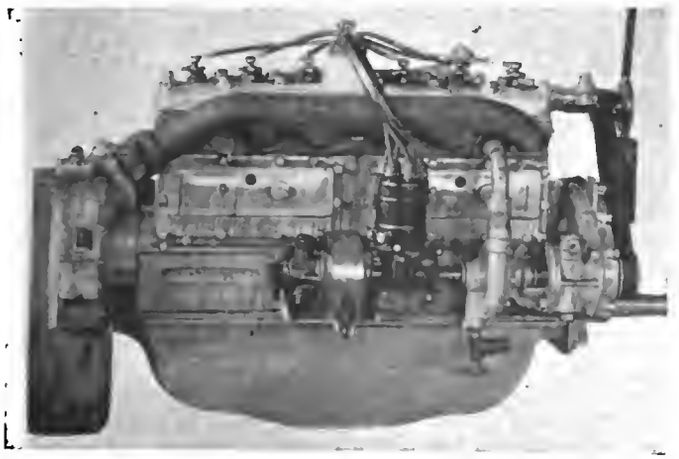
Standard timing is used with the intake valve opening at 15 deg. after top center and closing 50 deg. before bottom center. The exhaust valve opens 45 deg. before bottom center and closes 10 deg. after top center. The compression of the engine is 75 lb. absolute.

Lubrication is by accommodation pressure and splash feed with a 1½ gal. reservoir in the bottom pan. From this the oil is drawn by a plunger pump which is driven by an eccentric off the camshaft. There are direct leads from the pump to the main bearings which thus receive a supply of oil under pressure. The other leads go direct to the crankcase where the oil is led to splash troughs placed beneath each connecting-rod throw. Provision is made for the mounting of an oil pressure gage and this may be regulated by an adjustable relief valve.

Complete Westinghouse equipment is used throughout, even to the fitting of an ammeter and voltage regulator. It is a two-unit layout with a reversible switch which alters the direction of current flow automatically so that the contact points of the breaker box are prevented from pitting. For engagement with the flywheel a Bendix gear is used. The battery is a Willard of 80 amp. hr. capacity. Two sets of bulbs are provided in the headlights and there is also a dash light which can be employed as a portable lamp by means of a 12-ft. extension cord.



Details of the three-speed gearset and floating axle used in the 1917 Glide



Right side of Glide six engine, showing the generator and ignition distributer mounting

Gasoline is fed by means of the Stewart-Warner vacuum system which is mounted beneath the hood and operates in connection with a 16-gal. tank at the rear of the frame. Carbureter is a Rayfield and is provided with an efficient choking device which renders it unnecessary to prime the engine through the petcocks even in the coldest weather.

From the engine the power is taken by a dry multiple disk clutch having twelve steel plates. Six of these are faced with Raybestos. The selective gearbox is Brown-Lipe, mounted in an aluminum case, to cut down weight. From this the drive passes through a Spicer universal joint which is dustproof and self-lubricating. The propeller shaft is hollow, having a tubular section and taking the drive directly to the pinion shaft upon which is mounted the spiral bevel pinion. This transmits the power to the floating axle shafts through the Brown-Lipe differential. Two sets of brakes with 14-in. drums having a face width of 2 in. are bolted to the rear wheels. Wheelbase is 119 in.

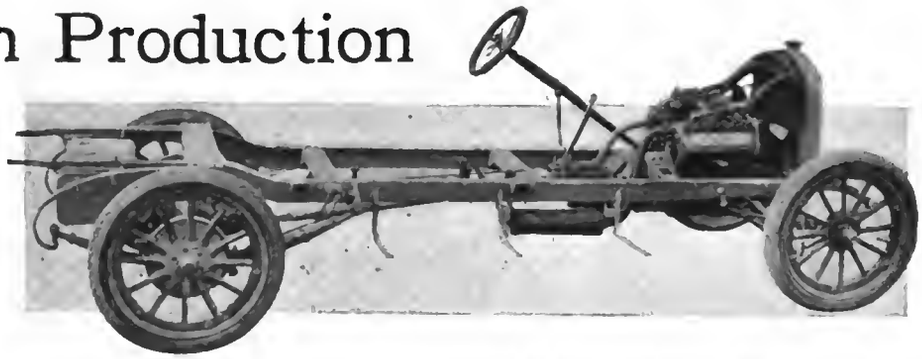
Hotchkiss Drive Used

Hotchkiss drive is used as both the propulsion and torque strains are absorbed in the springs. This is in conformity with the policy to be noted throughout in keeping the car as light as possible. The tire sizes are 34 by 4.

At the price, $1,125, full equipment is included. The price mentioned is for the five-passenger body. A detachable sedan top can be had for $200 additional.

Yale Eight in Production

New Seven-Passenger Car Is Mounted on Chassis Made Up of Standard Units



Chassis of the Yale eight, showing three-quarter elliptic type of rear springs, fuel tank mounting and installation of unit power plant in the frame

THE Yale Eight, which is produced by the Saginaw Motor Car Co., Saginaw, Mich., is characterized by the use of standardized products throughout. For the present it will be supplied only in seven-passenger form at $1,350, though the addition of a Winter top is contemplated. The standard color is ivory white for the body with black fenders and trim. Yale blue and black is an optional finish furnished without extra cost.

The engine used in the new car is built by the Saginaw company and adheres to standard practice in design, having its 3⅛ by 4½-in. L-head cylinders cast in two blocks of four each. Formula horsepower is 31.25. The carbureter is a Rayfield. The Remy ignition unit is acessibly mounted directly at the front of the V. The electric lighting and starting system is a two-unit outfit and the battery is a Willard.

Thermo-Syphon Cooling

Lubrication is primarily by force feed with auxiliary oiling by splash. Cooling is by thermo-syphon. The clutch is a multiple disk type transmitting power through a Muncie three-speed selective gearset in unit with the motor. Hotchkiss drive is a feature.

The chassis has a 126-in. wheelbase and 34 by 4-in. tires are used, with non-skid in the rear. Axles are Timken and steering is Lavine.

Wind Resistance Minimized

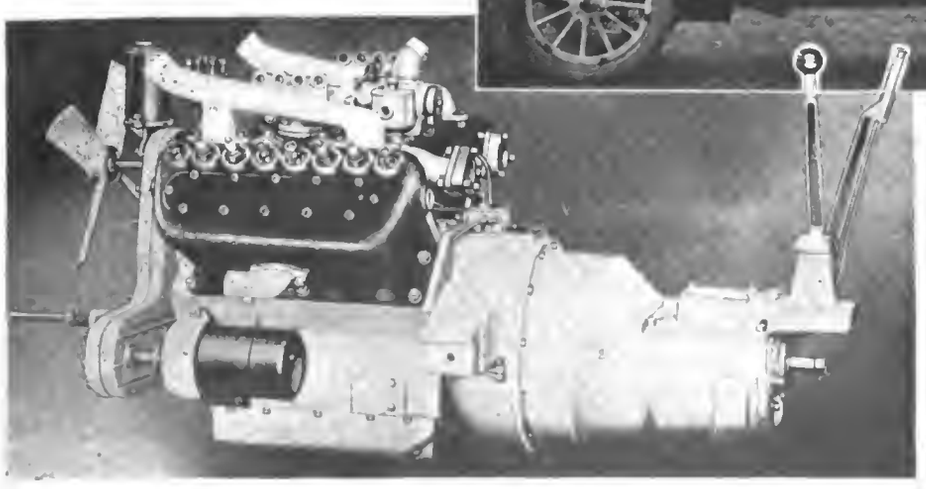
The attempt to reduce wind resistance to the minimum is apparent in the body design. The hood is tapered to blend well with the rather deep cowl and the sides are perfectly smooth. The windshield is smartly raked. There is a cowl at the back of the driver's seat which serves to house the auxiliary seats. All doors are fitted with pockets. The upholstery is leather and the backs of the seats have been moulded to fit the backs of the occupants.

Comfort an Aim

Great care has been taken to insure excellent riding qualities, and to this end the weight has been proportioned over front and rear axles only after long experiment. The spring suspension is normal in front, but in the rear there is modification of the three-quarter elliptic idea, which, however, does not appear unusual. The springs are 56 in. long.

The Saginaw Motor Car Co. has recently purchased the plant of the American Electric Wheel Co., which will be used to facilitate production. The E. B. Sutton Sales Co. has taken over the entire distribution of the Saginaw company. Headquarters have been established at the factory.

The eight-cylinder, seven-passenger Yale touring car which is now going through production. It has a 126-in. wheelbase, three-speed selective gearset and uses 34 by 4-in. tires. Cooling is by thermo-syphon and Hotchkiss drive is a feature. With complete equipment the car sells for $1,350



Yale eight-cylinder unit power plant. It has a bore of 3⅛ in. and a stroke of 4½, the formula horsepower rating being 31.25. The generator mounting is shown, carburetor and ignition units being carried in the V between the cylinder blocks

Burford Truck in 2 and 4-Ton Models

Internal Gear Drive Used on Smaller and Worm Replaces Chain on Larger of New Vehicles

TWO models, a 2-ton and a 4-ton, will compose the line of the Burford Motor Truck Co., Fremont, Ohio, for 1917. The internal-gear drive is used on the smaller chassis and a worm axle on the larger, the former being a continuation of last year's practice and the latter a change from the chain drive employed previously.

Engines Are Similar

The engines used are similar on both models, though different in size and in the fact that the smaller has block cylinders while the larger has pair castings. Dimensions are 3¾ by 5½ in. for the 2-ton and 4½ by 6¾ in. for the larger model.

Lubrication has been cared for particularly, oil being forced to the main crankshaft bearings by a plunger pump, and also supplied to dip troughs for the connecting- rods. Oil pump and strainer gauze are both very easily removable.

On the side of the cylinders remote from the camshaft there is a front end gear which drives the water pump, and the Eisemann magneto is coupled to the water pump shaft by a universal joint. The pulley for the fan belt is set on the same line, just in front of the water pump, keeping the belt high up and so well protected from the destructive action of oil and water.

Difference in Gearsets

On the 2-ton model the flywheel is contained in a bell housing which incloses the leather-faced cone clutch and supports the three-speed gearset, but the 4-ton type has a separate gearbox mounted independently and giving four speeds. This large gearset is of rugged construction, having gears 1½ in. wide with a 5-7 pitch, which makes for great tooth strength. Driveshafts and transmission gears are all chrome-nickel steel.

Strength in frame and springs is obtained by the use of high-quality steel and ample proportions. Radius rods are employed on the 4-ton model, but the smaller truck has Hotchkiss drive, the springs taking both torque and load. There is plenty of load space, the 2-ton being obtainable with either 132-in. or 144-in. wheelbase, and the 4-ton with a wheelbase of 175 in. Throughout both chassis a number of New Departure ball and Bower roller bearings are used.

Brakes Differ

There is a little difference in the brake equipment, the smaller having the conventional expanding brakes in the wheel drums, but the emergency brake acts on a drum attached to the bevel pinion shaft. This axle is made in the Burford plant. The 4-ton has a Sheldon axle, and uses Sheldon double expanding brakes.

Special Bodies Made

Tires are 36 by 3½ on the 2-ton, single in front and dual rear, while the 4-ton has 36 by 5 in., similarly disposed. The smaller chassis lists at $2,250 without body or cab, the latter costing $50 extra, and the 4-ton chassis sells for $3,600. Bodies of any kind can be supplied on special order. A fore-door cab can be supplied at an extra cost of $50.

Both models are electrically lighted, employing Willard storage batteries of the 6-volt, 80 amp.-hr. type. Each model also comes complete with horn, jack and tool kit.

The steering gears are of the conventional worm-and-nut type, with an 18-in. wheel on the 2-tonner and a 22-in. wheel on the 4-tonner. Right drive is adhered to in both models.

Colorado To Have 45,000 Cars

Secretary of State Estimates Registration Increase of 50 Per Cent Before End of 1916—Over 200 Manufacturers Represented—Analysis by Makes

By H. G. Hedden

DENVER, COL., Sept. 16—Secretary of State Ramer estimates that automobile and motor truck registration in Colorado will pass the 45,000 mark before the close of the year 1916. During the first 6 months of the year 36,231 cars and trucks were recorded, representing the products of over 200 manufacturers. This is a gain of 14,405 cars or 66 per cent over the 21,826 registered during the same period in 1916. When the 45,000 mark is passed the increase over last year will be over 50 per cent. Mr. Ramer estimates that the 40,000 mark was passed early this month, which registration means one motor vehicle for every 20 of Colorado's 800,000 population. This estimate is based upon partial returns received for July and August, upon the calls from County clerks for more license tags and the continued heavy sales reported by State distributors of cars.

$150,000 in Fees

Receipts from motor vehicle license fees in Colorado for 1916 will total between $150,000 and $175,000. No count has been made thus far, however, and the gain will depend upon the ratio of high-power cars. The license fees are $2.50, $5 and $10, for up to 20 hp., 21 to 40, and above 40, respectively. Inasmuch as the Fords, which pay only $2.50, represent 43 per cent of the total for the first half of this year, as against 34 per cent for the same period last year, it will be seen that the gain in receipts can hardly keep pace with the gain in number of cars registered.

The registration shows the following division of cars, according to class and horsepower:

	Denver	Outside	Total
Gasoline passenger cars up to 25 hp.....	4,912	15,762	20,674
Gasoline passenger cars above 25 hp.....	4,153	8,368	12,521
Gasoline trucks	440	181	621
Electric passenger cars	471	82	553
Electric trucks	67	6	73
Stanley steamers	65	75	140
Dealers' cars, unclassified	270	1,309	1,579
San Miguel County, unclassified.....	...	70	70

This shows a comparative ratio of approximately 24 per cent for Denver and 76 per cent for the outside counties in the low-power class gasoline passenger cars, with 33 per cent for Denver and 67 per cent for the outside territory in the class above 25 hp.

15,727 Fords Registered

An analysis by make of all the registrations available to date in Colorado shows that there are 15,727 Fords on record,

Various makes	169	145	314
Grand total	10,045	25,931	35,893

NOTE:—*Includes trucks. **Includes electric trucks. †Trucks. ††Includes trucks and steam passenger cars.

Overland holding second place with 2926, Buick third with 2369 and Maxwell fourth with 1707. Of the Fords 3494 are registered in Denver and 12,233 in the rest of the State. There are 659 Overlands in Denver and 2267 outside the city. Denver has 437 Buicks as compared with 1932 for the balance of the commonwealth and 534 Maxwells as against 1173 outside.

These four cars held the first four places last year, but Overland is now credited with second position, which was held by Buick last year.

Of the total of 35,893 registrations available when the analysis by make was undertaken this week, 34,598 were gasoline passenger cars, 335 gasoline trucks, 142 electric vehicles, including passenger cars and trucks, 140 steam machines and 314 miscellaneous. The latter being those whose make and type were not apparent from the registration records. The tabulation herewith shows the number of each make registered in Denver and the rest of the State, the number in each county being given in the second table. The county registration is not entirely complete but approximates the correct figures very closely.

Increased Gains Each Year

A study of the registrations in Colorado for the past three years brings out strikingly the tremendous increases made each year.

To the 1913 registration of 13,624 cars, 1914 added 4809 cars, or an increase of 35 per cent, while 1915 showed a gain of 9821 cars, or 53 per cent, over 1914, and this year promises a gain of 15,000 to 18,000 cars, or more than 50 per cent over last year.

The record for the lone carless county is still held by Dolores County, located in the extreme southwestern corner of the State, highly mountainous, thinly settled and with few roads.

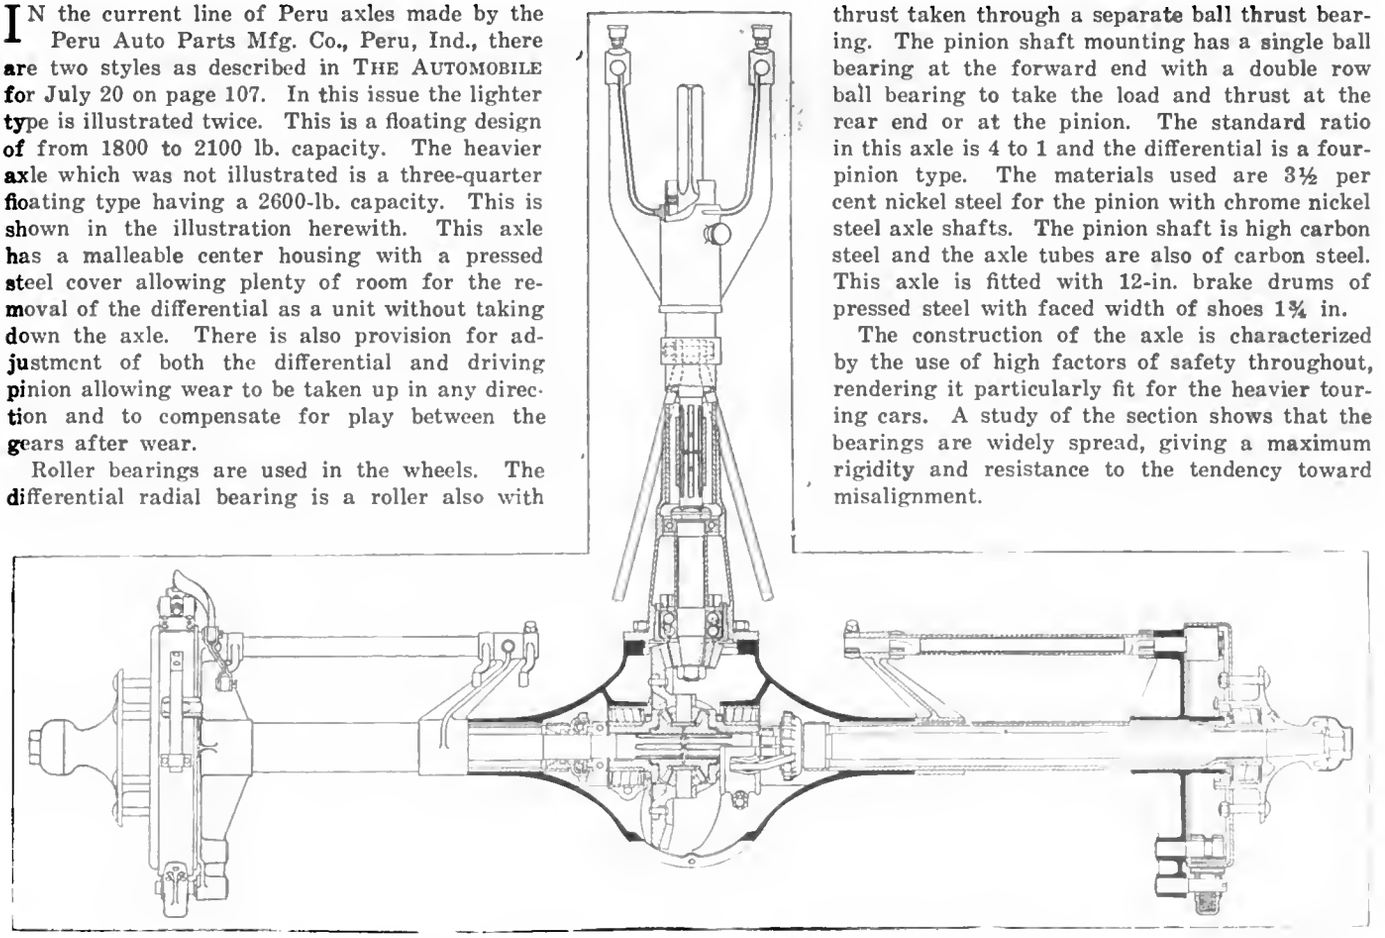
Peru 2600-Lb. Axle with Malleable Housing

IN the current line of Peru axles made by the Peru Auto Parts Mfg. Co., Peru, Ind., there are two styles as described in THE AUTOMOBILE for July 20 on page 107. In this issue the lighter type is illustrated twice. This is a floating design of from 1800 to 2100 lb. capacity. The heavier axle which was not illustrated is a three-quarter floating type having a 2600-lb. capacity. This is shown in the illustration herewith. This axle has a malleable center housing with a pressed steel cover allowing plenty of room for the removal of the differential as a unit without taking down the axle. There is also provision for adjustment of both the differential and driving pinion allowing wear to be taken up in any direction and to compensate for play between the gears after wear.

Roller bearings are used in the wheels. The differential radial bearing is a roller also with thrust taken through a separate ball thrust bearing. The pinion shaft mounting has a single ball bearing at the forward end with a double row ball bearing to take the load and thrust at the rear end or at the pinion. The standard ratio in this axle is 4 to 1 and the differential is a four-pinion type. The materials used are 3½ per cent nickel steel for the pinion with chrome nickel steel axle shafts. The pinion shaft is high carbon steel and the axle tubes are also of carbon steel. This axle is fitted with 12-in. brake drums of pressed steel with faced width of shoes 1¾ in.

The construction of the axle is characterized by the use of high factors of safety throughout, rendering it particularly fit for the heavier touring cars. A study of the section shows that the bearings are widely spread, giving a maximum rigidity and resistance to the tendency toward misalignment.



Section through the Peru 2600-lb. axle, which is a three-quarter floating type

Liberty Production on Quantity Basis

In Half Year of Company's Existence Scientific Plant Has Been Developed and Sales Approach $5,000,000

AN excellent example of the rapidity of industrial organization and immediate launching into manufacturing activity which is characteristic of the automobile industry, is the progress made in 6 months by the Liberty Motor Car Co., Detroit, Mich. This company, though incorporated only last February, already has a scientifically laid out factory and has been turning out cars in quantity for 2 months. The merchandising side of the business has kept pace with the manufacturing end and sales of the new Liberty six are approaching the $5,000,000 mark, distributing representation having been secured in practically all the leading cities of the country.

The first Liberty car was on the road in April. The factory buildings formerly occupied by the R-C-H Corp. were secured and remodeled to suit the new conditions. New buildings were constructed and old ones rearranged; and equipment to care for modern progressive assembly seemed veritably to be in the plant over night, so industriously did the entire organization work.

By July 4, all was ready; materials having been purchased and delivered, and everything in order. According to a prearranged schedule, cars bearing the Liberty name were being produced long before the end of July, and in presentable quantity.

Ideal Assembly Plant

The buildings are one story and spacious so as to make an ideal assembly plant. Progressive assembly, following a chain system that is slightly modified to meet the needs of the concern, is used. A moderately inclined track has been built down the center of the largest of the group of buildings, this track being about 275 ft. long. At the starting point it is elevated about 1½ ft. above the floor, and at the finish end it slopes down to floor level. The object of this very slight incline is to make it very easy to move the cars along after each operation. A slight push moves the vehicle without effort, and gets away from the necessity of a power conveyor of any sort. Further, the elevating of the track makes it more comfortable for the men, who can work standing at normal height without platforms or falsework. This results in higher speed and, consequently, greater production.

The Assembly Circle

About thirty cars can be accomodated by this assembly track at one time, and the chassis parts are stored on either side of the track. Beginning at the opposite end from the start of the inclined final assembly track, the frames commence their journey through the frame and spring assembly departments and wind up at the chassis paint. Simultaneously in another building, the unit power plants are assembled and prepared for the block test. After passing this examination, the motors go to a position beside the track from which they can advantageously be assembled to the chassis. Thus, beginning at one end, a swing in a complete circle is accomplished, and when discharged from the main line, the completed cars are road-tested and then driven 100 ft. to the long loading platform.

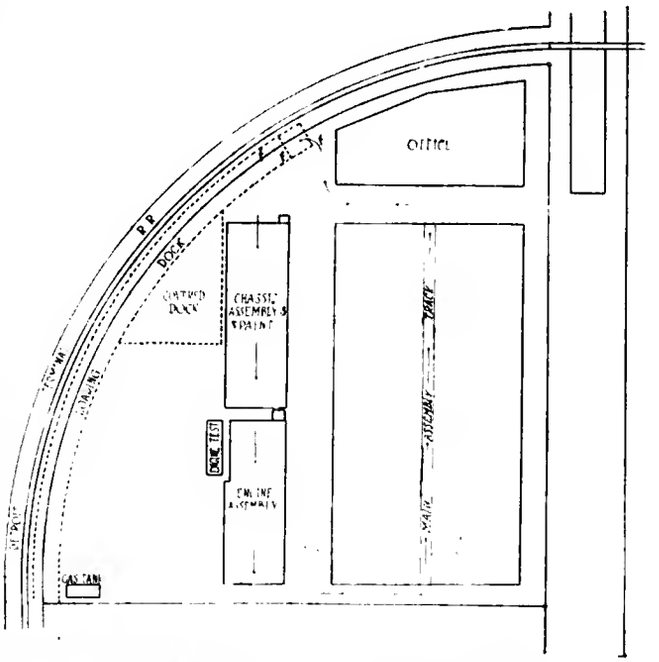
This summary of operations will show that Liberty has laid out its plant scientifically, and in accord with the best experience in building cars rapidly and substantially. It shows that entering into the manufacture of automobiles to-day is no venture for a weak organization, but that brains and experience, backed up by a reasonable amount of money, can succeed even against the great handicap of going into a field of manufacture that is now most keenly competitive.

15.4% of N. Y., N. J. and Pa. Roads Are Bituminous

ROADS treated with bituminous preparations constituted 15.4 per cent of the highways in the three middle Atlantic States, New York, New Jersey and Pennsylvania, in 1914, as compared with 1 per cent in the same States in 1909. This improvement is entirely due to the increase in the use of automobiles and trucks, according to the third 5-yearly study of road mileage, road types and highway finances in these States reported by the Office of Public Roads and Rural Engineering in department bulletin No. 386.

Approximately 9 per cent of the improved road mileage of the three commonwealths is now surfaced with concrete brick or other of the more substantial materials used in road construction as compared with 1 per cent in 1909. In 1904, when the first road study was made neither bituminous nor the more substantial roads were found, untreated macadam and gravel roads predominating. Roads of the unimproved type were reduced from a percentage of 51 to only 39.3 in the 5 years from 1909 to 1914.

On Jan. 1, 1915, the three States mentioned had roads totaling 185,770.84 miles, Pennsylvania having approximately 91,500, New York 79,000 and New Jersey 15,000, these statistics being exclusive of practically all streets in incorporated cities and towns. New Jersey added 17 per cent of surfaced roads in the 5 years from 1909 to 1914, Pennsylvania 7 per cent and New York 3.5 per cent.



Layout of the factory buildings of the Liberty Motor Car Co.

Progressive Assembly System Speeds Up Liberty Production

At the start of the assembly line in the factory of the Liberty Motor Car Co., Detroit, Mich. The chassis run down the track accumulating their component parts as they progress. Note the engine being lifted into place at the right and the overhead runways delivering wheels from the stockroom

The Rostrum

Why Four-Cylinder Pistons Are Larger

EDITOR THE AUTOMOBILE:—Will you kindly tell me why the piston is larger in four-cylinder cars than in six and eight-cylinder cars and why they will develop more power than a four-cylinder?

Harrodsburg, N. Y. H. G. S.

—The reason that the bore of the four-cylinder motor is in general less than that of six and other multi-cylinder engines, is simply because of the fact that more power than is necessary for the car is not desired. Every cylinder assembly acts as a separate engine in supplying power. The same amount of power can be obtained from six smaller cylinders as from four larger ones. Hence, to secure the desired amount of power with four cylinders, it is natural that each of the cylinders should be made larger.

Looking at the matter from another angle, that of piston displacement, it will be remembered that displacement is a direct factor of power. If a displacement of, say, 300 cu. in is desired and if enough power will be secured from this displacement, it would be obtained by using four cylinders of 75 cu. in. displacement or six cylinders each having 50 cu. in. displacement. Naturally, the pistons for the 75 cu. in. cylinder will be larger than those for the 50 cu. in.

Naphthalene Not Recommended in Fuel

Editor THE AUTOMOBILE:—Please advise me as to the use of naphthalin or naphthalene with flakes in gasoline for increasing mileage and as a carbon remover. It has been recommended to use a teaspoonful to every 5 gal. of gasoline and I am told that this substance is put up under many names and sold for that purpose. Please advise me as to its qualities and how it works and if you advise me to use same, giving reasons for your conclusions.

Fall River, Mass. E. J. D.

—The use of naphthalene or, as it is commonly known, camphor, is not recommended in gasoline. As a matter of fact it will deposit as much carbon as it will remove and will result in a sooted engine. A simple experiment which will readily show you the carbon-forming tendencies of camphor may be performed by simply holding a camphor or mothball over an open flame. The carbon will leave the camphor in long string-like formations.

Compression Bad on Three Cylinders

Editor THE AUTOMOBILE:—I have a 1916 model 43 Oldsmobile which has poor compression on all but one cylinder when cold, but does not show so much difference when hot. I have had the head off and ground the valves. I think it is in the gasket joint as the old gasket showed black carbon streaks, especially between cylinders. It hasn't the power it should have and has only run 2200 miles. Would it help any to put in two gaskets and shellac all sides of them, or is there anything else that will make it hold?

2—I am getting about 15 miles per gallon of gas. How many should I get with a new Stromberg carbureter?

3—Will this carbureter increase the power acceleration speed and make starting easy?

4—Is the Fracto a good device for headlights? Will it prevent glare and give good driving light?

Kenosha, Wis. T. A. F.

—Since the old gasket shows carbon streaks it is quite likely that you are right in your surmise that the car is losing power due to leakage. The new gaskets well shellaced may remedy the trouble. Also, go over the intake manifold connections very carefully and be sure that there are no air leaks around these.

2—It is pretty difficult to state what mileage you should get to a gallon of fuel without knowing how fast you drive, what load is carried in the car and other details which have their effect. In all probability, however, 15 miles to a gallon is a good average consumption.

3—In fixing upon a carbureter for their car the Oldsmobile engineers have no doubt taken all the matters which you mention into consideration, and while it is within the realms of possibility that you may secure a gain by changing your carbureter there is no reason why you should not get satisfactory service from the one which is on your car.

4—THE AUTOMOBILE has never had an opportunity to test out this device, but no doubt you could secure a demonstration from its manufacturers.

Redesigning Michigan Radiator

Editor THE AUTOMOBILE:—I desire to make a change in the radiator design of my 1913 Michigan car. I have designed one of the following dimensions and would like to know if it is large enough to cool a four-cylinder motor of 4¼ by 5¼ bore and stroke. The height is 25¾, width 22½ and 3¾ in. through cross section. The design is the same as the 1916 Mercer.

Pittsburgh, Pa. N. H.

—The radiator you mention would be sufficient, provided you have good pump delivery. The cooling of an engine does not depend so much on mere capacity of the radiator as it does on the volume of water that is handled in a unit of time. The purpose of the radiator is to carry a given number of B.T.U. from the engine in a given amount of time. Generally, the thermal units lost through the cooling water are about 35 per cent of the heat taken into the engine with the fuel. Under abnormal conditions, such as climbing long hills, this percentage will increase to as high as 50 and if the cooling chamber is too small it will go above the capacity of the radiator, causing overheating.

The method of determining the amount of heat carried off by the radiator is to first measure the quantity of water in cubic feet passing through the cooling system in 1 min. The temperature of the entering water is then subtracted from the temperature of the water leaving the jackets, giving the range between extreme temperatures. This temprature range is multiplied by the cubic feet of water passing through in a minute to determine the B.T.U. per minute. Knowing the calorific value of the fuel, the theoretical radiator can be readily determined in the manner suggested.

As a matter of fact manufacturers of cars do not determine their radiator size so much by the theoretical calculation as they do from a knowledge of what can be expected from a given size engine, a pre-determined pump and a known radiator size. This is a matter of development and even calculating on this basis errors have been made which have resulted in a necessary increase of radiating surface. Radia-

tors of different forms have different efficiencies and the mere capacity and dimensions of a radiator do not tell anything unless its efficiency is known. You do not mention the form of radiator you are employing, but, assuming it to be of the honeycomb type, it will be sufficiently large if the pump capacity is great enough to keep the radiator filled with rapidly flowing water at low engine speeds.

Even the fan design is of greatest importance in cooling. A fan that is sufficient for one radiator will be bad for another. The reason for this lies largely in the shape of the radiator, which may be such that it does not permit the fan to draw through all sections. A simple test can be made to determine the area of draw of the fan by placing small pieces of paper against the outside of the radiator when the engine is turning over at idling speed, and seeing if the paper remains drawn against the face of the radiator. It very often happens that certain areas of a radiator have a positive back current or eddy passing through them which instead of pulling cold air from the exterior of the car gives a flow of warm air which has been heated from its confinement beneath the hood.

Information on Stearns-Knight Engine

Editor THE AUTOMOBILE:—What are the most difficult features to overcome in the manufacture of a Knight eight engine? What part of the motor would be most likely to give trouble in operation, that is, in ordinary touring service?

2—Kindly illustrate the Stearns-Knight six engine in THE AUTOMOBILE. I wish to know the distance from driveshaft of transmission to front of engine, also width from tip to tip of arms that the engine is hung on, and distance between front and rear arms.

Swan Lake, Miss. H. D.

—In manufacture there is little doubt but that the grinding work is the thing which must be watched closest on a Knight eight-cylinder engine. This must be accurate for all cylinders. As for trouble in operation, there is no reason why any part should be conspicuous in this respect after manufacture has been carefully carried out.

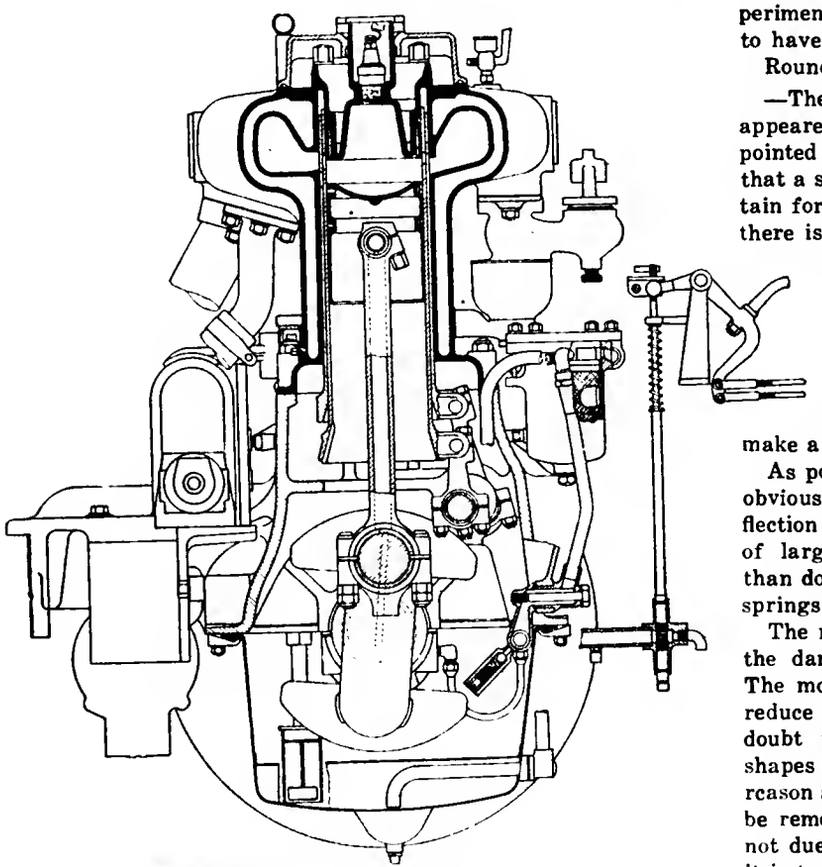

Fig. 1—Transverse section through Stearns-Knight six-cylinder engine

2—The Stearns-Knight engine is shown in section in Fig. 1. The distance from the driveshaft of the gearset to the front of the motor is 39⅜ in. The width of the arms in front is 20¾ in. and at the rear 26⅞ in. The distance between the front and rear arms is $18\frac{13}{16}$ in.

Believes in Full Elliptic Springs

Editor THE AUTOMOBILE:—There has been much speculation as to the most comfortable spring for the automobile, but strange to say, the full elliptic spring is not mentioned. This is probably due to the fact that so few have had the experience of riding in cars fitted with these springs, as the conventional half and three-quarter elliptic are mostly used.

I claim that there is nothing that can approach the full elliptic both front and rear, with the front spring slightly tilted backward, as in the Franklin, to receive road shocks. This may seem a broad assertion, but it is conceded by everyone who has had experience. There may be a few very heavy, high-priced cars fitted with deep cushions and shock absorbers that give comparative ease, but I am speaking of the ordinary size car. This also holds true with respect to pleasure wagons as long ago the elliptic spring was used. Then came the desire for something better and all sorts of springs were tried, but they soon disappeared and the elliptic came back and stayed because the principle was right.

I would like to ask why manufacturers of automobiles do not use them more. Is it the cost, or the difficulty of attachment on a steel chassis, or both? Is it the appearance that is objectionable? There are thousands of cars made to-day that meet every requirement except riding qualities, and we believe it would be a big selling factor if some other leading makers would adopt the elliptic spring. It sold my car after trying a score of others and after using it 5 years and experimenting with different models it would seem a hardship to have to change.

Round Top, N. Y. J. W. F.

—The point you bring up is covered in an article which appeared in THE AUTOMOBILE for Sept. 7, page 393. As pointed out in this article, by A. Ludlow Clayden, the idea that a spring had some special virtue because it was of a certain form has been pretty well exploded. On the other hand, there is no doubt that certain forms of springs have certain advantages but no spring is easy riding simply because of its external shape. It is rather in the development of its individual units that the secret of its success will be found alive. The length of the spring and the number of leaves have a marked effect regardless of the shape, and the ratio of sprung to unsprung weight of the chassis will also make a material difference.

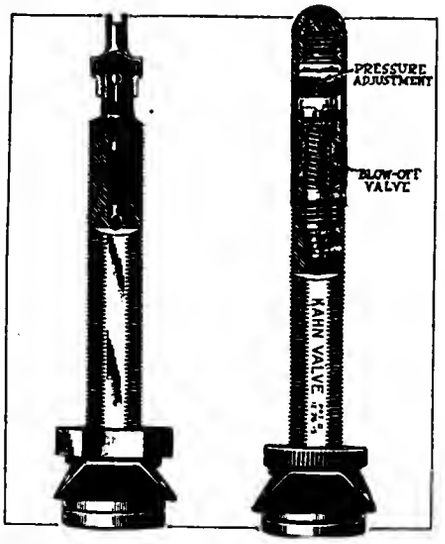
As pointed out, in the article mentioned, a long spring will obviously alter its curvature less for a given amount of deflection than a shorter spring, since the tangent to the circle of large diameter more closely approaches the periphery than does a tangent to a small circle. Fiber stresses on long springs are also less than on shorter ones.

The number of leaves in a spring has a direct effect upon the damping action which reduces the bounce or rebound. The more leaves there are the greater the surface area to reduce the throwing action of the spring by friction. No doubt manufacturers find that the chassis weights and shapes suit certain springs better than others, and for this reason a variation will be found in external shape, but it must be remembered that where easy suspension is obtained it is not due so much to the virtue of the shape of the spring as it is to the scientific way in which the spring design has been worked out.

ACCESSORIES

Armstrong Inner Tubes

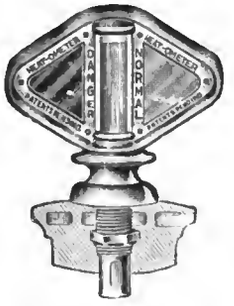
LONGER tube life and greater comfort and convenience for the car owner are the features claimed for Armstrong inner tubes, due to the use of the Kahn automatic valve. As shown in the accompanying illustration, this valve differs from the conventional type in that it is provided with a blow-off valve and a pressure adjustment so that when the desired degree of inflation has been reached no more air enters the tire and the whistling of the blow-off indicates the fact. The valve also differs from the usual type in that the valve stem fits through a hole in the body of the valve instead of having the stem screwed into the body of the valve. The operation of the pressure adjustment is clearly shown in the illustration. The inner tubes themselves are laminated, being made of heavy red rubber. The manufacturer controls the Kahn valve construction and states that the tubes sell at standard prices.—Armstrong Rubber Co., Inc., 118-122 Adams Street, Newark, N. J.



Left—Conventional tire valve. Right—Kahn valve used in Armstrong tubes

Heat-Ometer

This instrument is intended to apprise the driver of an overheated condition of his engine. As shown in the illustration, it is inserted through a hole drilled in the radiator cap and held in position by a lock nut. A diamond-shaped frame holds the glass indicator tube containing a sensitive liquid, which is pink at normal temperatures, but turns a deep purple when a dangerous degree of heat is reached. The frame at each side of the tube is paneled, one side being enameled pink and the other purple, enabling the driver to check the engine temperature by comparison. The standard size sells for $3, and the junior for $2.—Heat-Ometer Co., Inc., 1 Broadway, New York City.

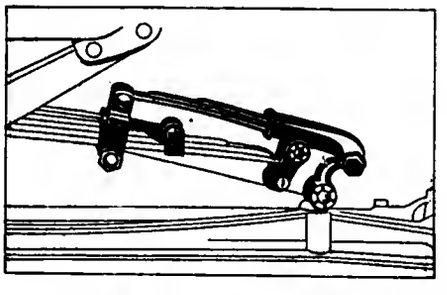


Heat-Ometer, a radiator gage

United Stands and Cranes

The Every-Way engine stand supports the engine while being overhauled, allowing the workmen to reach every portion with ease. The base is composed of two steel Z-bars bolted to the floor. To this two uprights of cast iron are fastened, cored hollow, with vertical slots in which the two steel brace clamping nuts travel. One upright is rigidly bolted to the base, the other being adjustable to take any width of engine, and is locked in a manner similar to the tail stock of a lathe. The supporting arms for the engine are steel angles, with numerous holes bored both in the horizontal and vertical sides. These angles are pivoted in the center to the two uprights. The engine is bolted to the angles by the same supporting brackets that support it in the chassis. The height to the top of the angles from the floor is 30 in.; length of angles, 42 in.; length of base, 52 in.; weight, 185 lb.

A portable, hand operated floor crane, having the high lift and deep overhang required in repair shop work, is also manufactured. A heavy cast iron base, mounted on truck wheels, supports the light steel superstructure carrying the hook, chain and drum. Because of the heavy base and light upper structure, the center of gravity is very low, preventing top-heaviness, and permitting a high lift. The U-shape of the base allows the crane to be placed in any desired position about the car, and is narrow enough to pass between the wheels of a car. Prices, No. 66, 1-ton, 6 ft. 6 in. lift, 33 in. overhang, $64; No. 76, 1-ton, 7 ft. lift, 33 in. overhang, $66; No. 80, 2-ton, 7 ft. 6 in. lift, 36 in. overhang, $82.—United Engine & Mfg. Co., Hanover, Pa.



Duplex cantilever spring for Fords

Hi-Comp Piston Rings

Two eccentric interlocking rings combine to form a single concentric ring. The rings are made from soft gray iron and ground together. It is not necessary to take the rings apart, as they expand sufficiently to fit over the piston. The design of the ring is said to give an equal expansive power on all parts of the cylinder, even though worn out of round. Two rings only are required for each piston. Price, all sizes to 5½ in., $1.65 each.—Continental Piston Ring Co., Memphis, Tenn.

Hi-Comp piston ring composed of two eccentric interlocking rings

Duplex Cantilever Springs

A new type of auxiliary spring for Ford cars has been developed in the Duplex cantilever spring. Upon each end of front and rear springs one of the Duplex springs is fastened, the upper end being secured at about half the distance to the middle of the standard Ford spring; the lower end under the front springs is attached to the present Ford perch and the front spring suspended

Every-Way engine stand, showing mounting of engine

from the Duplex spring, producing a cantilever action. This is said to eliminate side-sway and promote easy riding of the body. The rear Duplex springs attach to the perch in the same manner and add 5 in. to the span of the ordinary Ford spring. A set costs $15. —Duplex Cantilever Spring Co., Chicago, Ill.

Wegman Automatic Decarbonizer

This device supplies moisture to the intake manifold. Water is taken from the waterjacket above the carbureter down through tubing to the intake manifold, where it is carried with the mixture to the cylinders. The amount flowing is regulated by a needle valve used in connection with a sight feed glass on the tubing, and the supply is automatically shut off when the engine stops by a ball check valve. The device may be attached to any make motor by drilling and tapping two ⅛-in. standard pipe tap holes—one in the intake manifold and one in the waterjacket. It is claimed that the water is turned to superheated steam by the explosion temperature, which removes the carbon and increases the power of the engine. Price, $5.—Manufacturers Distributing Co., 400 Publicity Bldg., St. Louis, Mo.

Morton Front Wheel Brakes

Designed to supply a front wheel braking system for most makes of cars, no alterations to the car are required in the installation, and the brakes are said not to interfere with the proper operation of any part of the car. The brakes are of the expanding type, and so connected that the braking effort is applied to all four wheels at once. Quickness in stopping and prevention of side sliding or skidding are the advantages claimed for these brakes.—Morton Brake Co., 45 S. Tenth Street, Minneapolis, Minn.

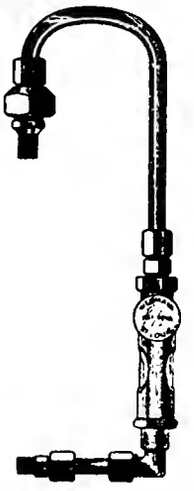
Comet Dash and Trouble Lamp

A combination dash and trouble lamp. On the dash, behind the lamp socket, is an automatic reel carrying 10 ft. of lamp cord. A spring in the rewind reel holds the lamp to the dash as a dash lamp. When used as a trouble lamp, it is freely portable. Price, $5.—Auto Specialty Co., Galesburg, Ill.

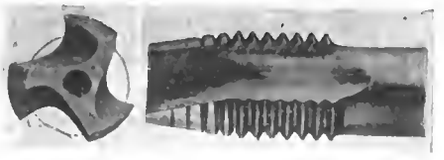
New Greenfield Tap

This tap, styled the "Gun" tap, is so made that it cuts with a shearing action, curling the chips ahead of the cutting edge and preventing clogging. The cutting edges are ground at an angle at the point, permitting the tap to cut freely and make clean, sharp threads. The body of the top has no cutting action, only serving to hold the work true to lead. The taps are made with two or three flutes only, left shallow so that the tap is nearly as strong as the solid stock. It is claimed that chipping is confined to the cutting edge, which may easily be reground. Regrinding may be repeated until only two or three full threads are left, it is said, and will retain its cutting size to that limit.—Greenfield Tap and Die Corp., Greenfield, Mass.

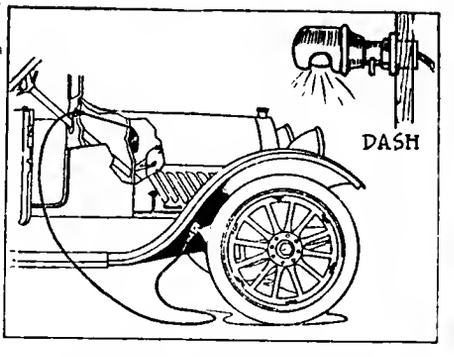
The Morton front-wheel brakes are of the expanding type, and connected with the rear-wheel braking system



Wegman Decarbonizer, which supplies moisture to the intake manifold, draining the water from the waterjacket



The new Greenfield tap



Comet dash and trouble lamp combined

Ventilating Hood Holder

This ventilator is intended to permit the free circulation of air beneath the Ford hood. These holders are substituted for the standard Ford clamps, and allow the hood to be clamped in an elevated position. The forced draft caused by the motion of the car passes over the motor, and escapes at the rear. The running temperature of the engine is lowered, and the performance of the engine is bettered, it is claimed. In cool weather the hood may be locked in the closed position. Price, per set of four, $4.50.—V Air Valve & Mfg. Co., Denver.

M. & E. Metal Shingles

Light, fire and storm-proof metal shingles are made up of copper, tinplate or galvanized iron. Constructed on scientific principles, this shingle can be put on more readily than any other form of metal roofing, it is said. Expansion and contraction are provided for; and the large overlap makes an absolutely tight roof of one-sixth pitch or over. A pleasing appearance, combined with reliability at a moderate cost are the advantages claimed for this type of shingle. Prices, Gothic, 14 by 20 size, 68 shingles per square, $4 painted, $5.75 galvanized.—Merchant & Evans Co., Philadelphia, Pa.

Lally Motor Tread Mill

Power for driving a saw or any machine requiring a power drive may be taken from the rear wheels of a car by the use of this device. It consists of a frame carrying a cross shaft with three pulleys and a jacking device which lifts the car wheels and presses them against the two outer pulleys on the shaft. When the engine is run the shaft is driven and power taken from the middle pulley by a belt. The jacking device is operated by a screw and the tension of the rear tires against the drums may be adjusted.—Lally Commercial Body Co., Everett, Mass.

Ventilating hood holder

Building vs. Assembling

MANY of the manufacturers who commenced their business as chassis assemblers, using stock parts throughout have recently changed their system, and some of them now make all the principal parts of their car. This has come about in two ways. In some cases the manufacturer has enlarged his factory and equipped to make his own parts in the parent plant, as for example the Hudson extension for the making of the Super-six engine. Others have bought up parts producing plants, as for example the complete absorption of various parts makers into the General Motors organization.

It is interesting to speculate as to the ultimate effect, and the reasons for the observed changes in policy. No doubt several automobile assemblers have been driven to making their own parts by failure of their original supplier to make deliveries on schedule. In other words the condition of the materials market has reacted via the parts maker and has mildly frightened the automobile producer. In other cases the desire for a distinctive design has been the mainspring.

Meanwhile the parts makers have all improved their plants and nearly all have enlarged; they have better facilities than ever before, so when the cost of raw material comes down again, the parts makers will be able to offer very tempting prices indeed. In conditions of enormous demand and high material cost it is less easy for the parts specialist to hold his own against the car builder with a fairly large output, than it is in normal times.

No other industry owes so much to detail specialists as does the automobile industry and it is hard to believe that the parts makers will not be able to retain their position as conditions ease, so any great extension of individual manufacture of complete cars is unlikely. In another 3 or 4 years we ought, however, to be able to see clearly when it does pay to make parts specially for one car and when it does not, a matter which is still debatable.

"Tanks"

THE huge war machines which have just made their appearance as participators in the British advance on the Somme seem, from the cabled reports, to be exactly what so many war story writers of the past have imagined. H. G. Wells pictured just such machines 10 or 12 years ago in one of his novels. and the impregnable motor car has been used by many another author of fiction.

A Matter of Cost

That such machines were possible, that even bigger ones could be built, has been known to automobile engineers for a long time. What has hitherto been lacking was sufficient funds to enable sufficient experiment to be made. No doubt these British crawling forts are the product of many experiments and many failures, and they have been built with no regard whatever to their cost.

Of course we are still ignorant as to the exact size and detail of these machines, probably very little detail will be available till the end of the war. One certain thing. however, is that they must be vastly heavier than the biggest caterpillar tractor ever built in America if their power of crumbling down houses and breaking off trees is as great as the daily press reports state, even though it is reported that the chassis used in their construction are of American manufacture.

There is no fundamental reason why one could not build a land traveling machine as big as an ocean liner if there was any purpose to be served, just as there is no doubt an automobile could be built that would do 200 miles an hour, if the incentive were sufficient. It is. however, not easy to see how monster land machines could serve any useful purpose in peace time although many other war creations have afterwards found their place in the scheme of things and history may repeat itself once more in this connection.

U. S. Troop Trucks

IT is about time that the United States government tried the motor truck as a means of transporting troops. The reflection of the French success on the Marne should be found in this country. Recently two regiments were transported 200 miles in 32 hours, using 132 trucks. This is only a start. Let us try longer distances with more men.

Open Price Value in Co-operation

Price Publicity and Profit-Sharing High Lights of Babson Conference

WELLESLEY HILLS, MASS., Sept. 15—The Third Babson Conference on Co-operation was held here Wednesday, Thursday and to-day. Its object is the promotion of co-operative competition, which includes the open price and profit-sharing.

The open price is the most radical part of the plan, for profit-sharing is quite extensively practised and is generally understood.

The open price means price publicity, and in those associations which are founded on this idea the members freely exchange the prices they make on different articles, the bids they submit on contracts, and even the cost of production.

It is opposed to price maintenance and yet it tends to reduce price cutting. The element of futurity is eliminated. No member tells what his price shall be, but, instead, tells what it has been or is now. This prevents unscrupulous buyers from playing one manufacturer against the other and beating down prices by false statements. But there is nothing to prevent any man making any price he wishes. He can sell below cost if he wants to. The big idea is that if all the prices are known to all there will be less tendency to cut ruinously than if all work in the dark and slash dangerously low to make sure of getting the business.

Open-Price Operation

The open-price plan is operated through associations, which exchange the information through a bureau. There are about twenty associations to-day and the plans vary in detail. In some all the data connected with a sale is given—price, customer's name and cost. In others less is given, running down to the price alone.

The open-price part of the conference was devoted principally to an explanation of plans now in effect. The speakers were: D. B. Doremus, Salt Producers' Association; Ernest H. Gaunt, Optical Manufacturers' Association; W. V. Spaulding, Leather Belting Exchange, and H. S. Wales, Pressed Metal Association.

Cost Finding

Another phase of the work of these associations is that of cost finding. Efforts are made to have manufacturers install systems that will tell them the exact cost of the product, which information will be of assistance in making prices. The speakers stated that cost systems disclosed some startling facts to manufacturers.

In the employees' profit-sharing part of the conference three plans were described:

1. Simple share in company's profits. Described by Everett Morse, president Simplex Wire & Cable Co., Cambridge, Mass.

2. Share in profits and stock interest in business. Plan used by Dennison Mfg. Co.; described by Mr. Dennison.

3. Share in profits under fraternal interest of company without interest in company. Plan of Ford Motor Co. Described by Dean S. S. Marquis, head of educational department of the Ford Motor Co.

—

Times Square Motor Supply Co. Formed with $1,000,000

NEW YORK CITY, Sept. 20—The Times Square Motor Supply Co. has been formed here to take over the business of the Times Square Automobile Co. and all its branches. The new company has $1,000,000 in preferred stock, all of which has been subscribed and 40,000 shares of common of no par value. The stock will be offered on the New York Curb.

All capital will be used in enlarging the business of the company, which plans to establish twenty new stores within 90 days and twenty more before May 1, 1917, making a total of fifty. Accessories will constitute the entire stock, neither new nor used cars being bought or sold.

Officers of the new company are: Morris Froehlich, president; Jesse Froehlich, vice-president; Louis Mansbach, treasurer; and John E. Gores, secretary.

—

Invents Two-Wheeled Armored Car

AUBURN, ILL., Sept. 16—S. J. Clark, this city, has invented a two-wheeled armored motor car, designed for military use, which he has submitted to the war department at Washington. The car is equipped with a small central wheel in front of the two main wheels. The principal object of the car is to protect men from fire while digging trenches, being easily shifted from point to point. It is also designed for patrol duty, operating under almost any kind of conditions, due to its light weight.

—

Crowther Chassis on View

ROCHESTER, N. Y., Sept. 15—A chassis has been assembled by the Crowther Motor Co. which incorporates the Duryea roller drive in which the power is applied to the rim of the wheel. This is now on exhibition at the Powers Hotel in this city. It is stated that the company will be soon ready for production in their Rochester plant.

U. S. Caterpillar Battery

Holt Machine Can Pull Big Guns at 3 M. P. H at a Big Saving

NEW YORK CITY, Sept. 20—Considerable excitement has been manifested in the daily press regarding the so-called Tanks or crawling forts in use by the British army. From the information that has leaked through the ever-vigilant censors it would appear that these are a super-developed caterpillar tractor, very possibly of Holt design as far as the chassis is concerned.

The success with which these heavy tractors seem to have been used on the other side lead to the natural question as to what has been done in this country along the same lines, and it is gratifying to note that while the United States has not as yet done anything on the heavily armored tractor very thorough data has been accumulated on the subject of tractor transport for heavy artillery.

It is understood that at the present time there is under process of organization a tractor battery in which an entire regiment with twenty-four heavy field pieces will be drawn by caterpillars. This organization will be ready, it is believed, in about a year and is to be stationed in the Hawaiian Islands. The battery which is to be known as the ninth heavy field artillery will have no horses at all, the caterpillar tractors taking the place of 1000 of these animals. The place of saddle horses will be taken by motor cycles and the reserve ammunition will be carried by motor trucks. It is very probable that this regiment will be equipped with artillery which will correspond to the famous German 42-cent. gun.

Full data as to costs, etc., have been worked out at the experimental station at Fort Sill, Okla., and it is found that in this heavy work the cost of the motor-drawn battery would be about $40,000 less than a horse-drawn one, and the annual saving of pay, clothing, rations and forage would be about $25,000.

—

A. S. A. E. Members Can Join S. A. E.

NEW YORK CITY, Sept. 20—Members of the American Society of Aeronautic Engineers can become members of the Society of Automobile Engineers without payment of initiation fees, provided these memberships are taken out within 90 days. This announcement was made in THE AUTOMOBILE last week, except that the name of the Aeronautical Society was used in error for the A. S. A. E. and it was stated that annual dues need not be paid. This should have referred to initiation fees.

$500 Electric in Boston?

Battery That Will Recharge and Marked Economy Features of New Car

BOSTON, MASS., Sept. 16—Plans are now under way here to build an electric car with a battery that will recharge itself when running on level ground, and which can run 2 or 3 days without getting a boost. It will run very cheaply, will weigh less than 1500 lb. and will sell in the neighborhood of $500. Plans are under way to place the stock on the market, and the men behind it are all big enough so that their names mean something. The man who has devised the machine has a national reputation in the electrical world, and is connected with the biggest company in the country making electrical apparatus.

An experimental car has been thoroughly tried out and it has proved a success.

More complete details regarding the new car will be available as soon as the manufacturing arrangements are under way.

Lane Trucks Out Soon

KALAMAZOO, MICH., Sept. 16.—The new plant of the Lane Motor Truck Co., Kalamazoo, will be turning out manufactured goods within a short time. M. H. Lane reports that the necessary parts for a large number of trucks have been ordered and that the output will be marketed rapidly as soon as the new factory is ready for the work ahead.

Light Four Tractor Tested

MARION, OHIO, Sept. 16—The Huber Mfg. Co. gave a demonstration of its Light Four tractor on the J. B. Guthery farm, located 2½ miles west of Marion, this week. The tractor pulled three 14-in. plows, plowing at the rate of a little better than 1 acre an hour. The furrow was 9 in. deep.

Bound Brook Oil-less Bearing Co. Adds

BOUND BROOK, N. J., Sept. 16 — The Bound Brook Oil-less Bearing Co., is erecting a re-enforced concrete addition, 50 by 100, to its plant No. 2, to take care of the increased business in Nigrum impregnated wood bearings.

Hench & Drongold to Make Automobile and Truck Bodies and Parts

YORK, PA., Sept. 16 — The Hench & Drongold Co., this city, large manufacturer of garden implements, has entered the automobile field as maker of wood work of all kinds for automobiles and trucks, including bodies and parts of both wood and metal. The company will also build special machinery and do machine and forge work. Special equipment has been installed in the company's large new plant, which covers about 6 acres.

Van Dorn Tool Doubles Capacity

CLEVELAND, OHIO, Sept. 15—The new plant of the Van Dorn Electric Tool Co., located on the heights above Cleveland has doubled the output of the company. The new building is three stories and is of steel, brick and concrete. It is located on a spur of the Cleveland Belt Line.

American Chain Salesmen Inspect New Bridgeport Plant

BRIDGEPORT, CONN., Sept. 15—At a convention of American Chain salesmen held recently, a thorough inspection was made by the men of the new plant which is being erected here. This will double the capacity of the Weed concern, as it includes 50,000 sq. ft. of floorspace. The roof is just being closed on one of a group of six buildings and a duplicate of this five-story building will be completed in 30 days.

Continental Begins Another Addition

MUSKEGON, MICH., Sept. 13—The Continental Motor Co. has begun work on the erection of a new automatic screw machine factory building, which will be one story high and of the saw-tooth roof style. When this building is completed the automatic screw machine department, which is now located on the third floor of the L factory building, will be moved into the new plant.

Kelly-Springfield May Move

AKRON, OHIO, Sept. 18—The Kelly-Springfield Tire Co. is considering the removal of its plant from this city to Cumberland, Md. If moved, the plant will be tripled in capacity. The Akron plant will be sold for, it is expected, $750,000, and negotiations are under way for the donation by Cumberland of $750,000 and a 75-acre site. The company now employs 1500 men, but in Cumberland would have 3000. Kelly-Springfield is paying $4 a share and earning about $12.

Maxwell Assembly Plant for Dallas

DALLAS, TEX., Sept. 13—The Maxwell Motor Car Co., Detroit, Mich., has purchased a site for an assembling plant to be the distributing point for five States. The Dallas plant will be the third of its kind to be erected by the company.

Master Calorite Plugs Adopted by P. O.

HARTFORD, CONN., Sept. 16—The postmaster general has awarded to the Hartford Machine Screw Co., manufacturer of master calorite spark plugs, the contract for the Postal Service.

Waukesha Motor To Expand

Increases Capital from $200,000 to $1,000,000—Adds to Plant Facilities

WAUKESHA, WIS., Sept. 16—The Waukesha Motor Co., Waukesha, Wis., manufacturer of motor car, truck and tractor motors, has increased its capital stock from $200,000 to $1,000,000 to provide for extensions to its plant. Work on a new office building is now under way, and plans are being prepared for large extensions of the machine shop, assembly department, and testing shop. The company has been obliged to decline acceptance of numerous large orders for engines because its facilities already are being pushed to the utmost by the orders now being executed.

Harroun Motors Buys Plant

DETROIT, MICH., Sept. 18—The Harroun Motors Corp., in which Ray Harroun is a principal, has bought the Prouty & Glass Carriage Co. plant at Wayne, and will begin the manufacture of a car designed by Harroun, as announced in THE AUTOMOBILE last week. First models were built in the Dodge Power Building. The car will be sold for less than $600.

Bosch Magneto Co. Adds Again

SPRINGFIELD, MASS., Sept. 16—The recent addition to the local works of the Bosch Magneto Co. is to be further augmented by an addition providing more than 60,000 sq. ft. Ground has already been broken for the new building, and it will be rushed to completion.

The addition is to be a single-story building, with saw-tooth roof providing maximum light and ventilation.

When this second addition has been completed there will have been more than 130,000 sq. ft. added to the Bosch works during 1916.

Maxwell Plant for Dallas

DALLAS, TEX., Sept. 16—The Maxwell Motor Car Co. has purchased a site for an assembly plant here, which will be the distributing point for five States. The plant is the third of its kind in the United States.

Brunswick-Balke Tire Plant Contracts Awarded—Plan Dwellings

MUSKEGON, MICH., Sept. 11—Construction work on the automobile tire factory of the Brunswick Balke-Collender Co. will be started soon, the contract for the building having been awarded. The

structure will cost $40,000 to $50,000, and will have 40,000 sq. ft. of floor space. It is to be ready for occupancy within sixty days.

In order to provide for the increase in the number of its employees, the Brunswick company has also contracted for the erection of about thirty double dwellings, to be occupied only by its own workers.

—

Loewe Is Brunswick-Balke Mgr.

MUSKEGON, MICH., Sept. 18—F. J. Loewe has been appointed general manager of the Brunswick-Balke-Collender Co., billiard and bowling alley fixture maker, which entered the automobile tire manufacturing field last April. For the benefit of its workmen the company has started construction work on a large number of double houses.

—

Russell Resigns from Bessemer

GROVE CITY, PA., Sept. 16—R. F. Russell has resigned as production engineer of the Bessemer Motor Truck Co. to become identified with the Air Reduction Co. in New York. Mr. Russell has been connected with the Bessemer for the past 3 years.

—

Taylor Joins Evapco Co.

DETROIT, MICH., Sept. 16—Kirk Taylor has been appointed sales and advertising manager of the Evapco Mfg. Co., this city, succeeding W. O. Seelye. Taylor was formerly assistant manager for the New Era Spring & Specialty Co. The Evapco company hereafter will sell only to jobbers.

—

Millar, of Auto Parts Mfg. Co., Dies

MILWAUKEE, WIS., Sept. 16—James D. Millar, secretary and treasurer of the Auto Parts Mfg. Co., Milwaukee, died of apoplexy this week, aged 62 years.

Imperial Brass Co. Expands

—

Will Have 150,000 Sq. Ft. After Additions Are Completed—24 Hr. Schedule

CHICAGO, ILL., Sept. 18—The Imperial Brass Mfg. Co., this city, will begin next week the construction of an addition to its factory which will double its floor space. The present building contains 75,000 sq. ft. and the addition will contain an equal area, giving a total of 150,000 sq. ft. The new foundry space will more than double the present foundry space. Like the present plant, the new building will be of heavy mill construction and will be erected on an adjoining site at Harrison Street and Racine Avenue. Bids are now being taken for the building work. Orders have been placed for the new factory equipment.

The company's plant has been running night and day for several months without doing any war business.

—

Ford Distributes $850,000

DETROIT, MICH., Sept. 18—The Ford Motor Co. has distributed $850,000 as bonuses among 1399 heads of departments, superintendents, foremen, and other employees, in sums of $100 and up. This is $120,000 greater than the 1915 bonus.

—

Tobin with Cutting, Armstrong & Smith

DETROIT, MICH., Sept. 16—F. D. Tobin, assistant district manager of the Willard Storage Battery Co., Detroit, has resigned to become affiliated with the Cutting, Armstrong & Smith Sales Co.

—

Iowa Rubber Plant in Bettendrof

DAVENPORT, IOWA, Sept. 16—The Iowa Rubber Tire Co., recently organized, will locate its plant in Bettendrof, a suburb of Davenport. A tract of 10 acres has been purchased, and an option secured upon an adjacent tract of similar size. It was necessary to locate the plant close to the Mississippi River, as 200,000 gallons of water will be consumed daily in the various processes of manufacturing tires. Ground will be broken on Nov. 1. An initial order for $100,000 worth of machinery has been placed. C. H. Roth, who recently resigned as vice-president of the American Tire and Rubber Co., has arrived in Davenport to take active charge of the department of sales of the new concern.

—

McQuay-Norris Men Promoted

ST. LOUIS, MO., Sept. 18—The McQuay-Norris Mfg. Co. has made the following promotions in its selling force: Frank J. Stanley of the traveling force is made manager of the Cincinnati branch; Howard W. Sweeney is made manager of the Denver branch.

—

Stockbridge Heads N. E. Winton

LONDON, ENGLAND, Aug. 26—Ball and Motor Car Co. of Cleveland has sent Frank W. Stockbridge to Boston to become manager of the New England branch on Commonwealth Avenue. He succeeds F. A. Hinchcliffe, who has taken the agency for the Jordan car.

—

Wizard Parts Co. Formed

BAY CITY, MICH., Sept. 15—The Wizard Auto Parts Mfg. Co. was recently organized here to manufacture a new steering device for Ford and other cars, invented by L. J. Weatherwax. It is said that several automobile manufacturers after having investigated the merit of the new invention have made propositions to Mr. Weatherwax for exclusive rights to use the device. Mr. Weatherwax is president of the company; C. J. Scheurmann is vice-president; F. B. Scheurmann, secretary-treasurer.

Selberling Field, Akron, Ohio, as it appeared Labor Day on the occasion of the field and track meet held by the Goodyear Tire and Rubber Co. This athletic carnival is said to be the largest ever held by a private corporation

Hydraulic Pfd. Issue $1,000,000

Pressed Steel Co. Plans to Retire Present Issue of $200,000

CLEVELAND, OHIO, Sept. 16—The Hydraulic Pressed Steel Co., this city, has issued $1,000,000 7 per cent cumulative preferred stock, which has been purchased by Borton & Borton. J. H. Foster, vice-president and general manager of the company, states that the new capital will be used in extending and developing the company's business, it being proposed to retire the present preferred issue of $200,000, which is callable at 102½. A sinking fund will be established Jan. 1, 1917, and each year thereafter $50,000 worth of the new stock will be retired. The stock will be callable at 107½. The company will not be sold.

Total net assets of the company will show an excess of three times the new preferred stock issue, and the net quick assets about one and one-half times. The earnings of the company for the past 2 years have averaged four times the dividend requirements of the new preferred issue. The subscription price has not yet been set.

—

General Bearings Corp. to Take Over Standard Roller

PHILADELPHIA, PA., Sept. 16 — The General Bearings Corp. is about to be organized here to take over the business of the Standard Roller Bearing Co., this city, which has been in the hands of receivers for 3 years. No information as to the personnel of the new company is ready for publication, but it was stated that the capital stock will be about $5,000,000.

The receivers, R. S. Woodward, Jr., and S. Laurence Bodine, are preparing their report to be submitted to the United States District Court in this city for approval. In the meantime an application has been made for the renewal of the present license which was granted by the Hess-Bright Corp., holder of the Conrad patents for ball bearings, and which is about to expire. The renewal is being asked for as a matter of protection to the new company and will be considered by the court.

The plans for reorganization, it was said, will allow the present stockholders to participate by paying an assessment of $7.50 on each share of common stock and $15 on each share of preferred.

—

$40,000 Co. to Make Visible-Measure Gasoline Dispenser

LOUISVILLE, KY., Sept. 16—The Visible Measure Gasoline Dispenser Co. has been incorporated here to manufacture, sell, install, rent and lease the Visible Measure Gasoline Dispenser. The capital stock of the company is $40,000, divided into 4000 shares of $10 each, and the limit of indebtedness which may be incurred is $10,000.

Incorporators and their holdings are: J. Henry Brady, 3000 shares; William A. Earl and William A. Pell, 10 shares each.

—

Materials Market Holds Steady

NEW YORK CITY, Sept. 20—Tin and cottonseed oil showed the greatest changes in the materials market quotations during the past week. Both were up, cotton seed oil by 58 cents per barrel and tin by 50 cents a 100 lb. Lead also increased so that it has now attained a level of 7 cents per pound. Lard oil left the dollar mark and ascended to $1.08. No drops in prices are to be noted in the quotations.

—

Calmont Resigns from Jackson

JACKSON, MICH., Sept. 11—G. C. Calmont, has resigned as advertising manager of the Jackson Automobile Co.

—

Ryan Heads Gibson Branches

INDIANAPOLIS, IND., Sept. 20—The Gibson Co., Indiana Overland distributors, has appointed P. J. Ryan as supervisor of its six branches.

Fuller Ouput Worth $700,000

Parts Manufacturing Concern Has Record Year—New Plant Is Planned

KALAMAZOO, MICH., Sept. 12—This has been the biggest year in the history of the Fuller & Sons Mfg. Co. The value of the output of automobile parts for the fiscal year 1916 as given by the officials is $700,000, as compared with $225,000 in 1915 and $75,000 in 1914. The working force, which was about fifty men in 1915, ran up to 225, and even 250 at times, during the present year. By 1918 the concern expects to have a new plant of more than twice the size of its present premises.

—

Ellis-Smith Replaces Rub-On

BUFFALO, N. Y., Sept. 16—The Ellis-Smith Mfg. Co., Inc., is the new name of the Rub-On Mfg. Co., Inc. The change became effective Sept. 1. The management and sales policy of the company remain the same.

—

Portage Rubber Raises Dividend to 10 Per Cent

BARBERTON, OHIO, Sept. 16—Directors of the Portage Rubber Co., this city, have placed the stock on a 10 per cent yearly basis by declaring a quarterly dividend for a time of 2½ per cent of the common, payable to stock of record Nov. 3.

—

Dividends Declared

Gray & Davis, Inc., quarterly dividend of 1¾ per cent on preferred, payable Oct. 1.

Springfield Body Corp., quarterly dividend of 2 per cent on preferred, payable Oct. 1, to stock of record Sept. 21.

Wilson & Co., Inc., quarterly dividend of 1¾ per cent on preferred, payable Oct. 2, to stock of record Sept. 20.

Stutz Motor Car Co., 2½ per cent on common, 1½ per cent on second preferred, and 1¾ per cent on third preferred, payable Oct. 2 to stock of record Sept. 15.

Billings & Spencer Co., Hartford, Conn., quarterly of 2 per cent, and an extra dividend of 3 per cent payable on Oct. 2.

Allis-Chalmers Mfg. Co., quarterly of 1½ per cent on preferred, payable Oct. 16 to stock of record Sept. 30.

Texas Co., quarterly of 2½ per cent, payable Sept. 30 to stock of record Sept. 15.

Saxon Motor Car Corp., quarterly of 1¾ per cent, payable Oct. 2 to stock of record Sept. 29.

G. M. C. Common Up $120 in Week

Market Strong in Many Issues —Chevrolet Increase $18 and Firestone $25

NEW YORK CITY, Sept. 19—General Motors common still remains the feature of the market with a net increase of $120 per share during the last week. This makes a rise of $155 in 3 weeks and is not only a new high mark for the issue itself but sets a record for the New York Stock Exchange, with one exception which is the sale of Northern Pacific at $1,000 per share during the panic of 1901.

Firestone came back during the week. It was off $30 a week ago, but its increase of $25 brings it back to $1,015 bid and $1,030 asked. Another rubber stock to show an advance was Miller which is now up to $265, an increase of $27 a share during the week. The other tire and rubber stocks remained quite firm with little fluctuation as compared with the more active stocks. Chevrolet, which was quite steady last week, took another forward move and increased $18 a share so that the closing price yesterday was $213.

—

Scripps-Booth Elects Directors

NEW YORK CITY, Sept. 18—The board of directors of the Scripps-Booth Corp., which was recently formed to acquire and operate the Scripps-Booth Co. and the Sterling Motor Co., of Detroit, is made up of the following: C. H. Booth, president; W. H. Little, N. J. Miller, W. L. Scripps, F. J. Sesenbrenner, Alfred P. Sloan, Jr., and T. P. Warner.

Up to the present time the production of Scripps-Booth cars has reached approximately 6000, about one-third of which has been sold in foreign markets.

—

Saxon and Stutz Stock on 'Change

NEW YORK CITY, Sept. 16—Stocks of the Saxon Motor Car Co., Detroit, Mich., and the Stutz Motor Car Co., Indianapolis, Ind., have been listed on the New York Stock Exchange, and will be traded in in a few days, or as soon as the permanent certificates are ready. The new stock of the General Motors Co. is being actively traded in on the Broad Street curb "when, as and if issued." Since Monday last the stock has advanced some 35 points.

—

Grant Earns $78,000 in August

CLEVELAND, OHIO, Sept. 16—Net earnings of the Grant Motor Co. in August amounted to $78,000. This is at the rate of 40 per cent on the common stock after paying the dividend on the preferred.

—

Gasoline 1 Cent Lower in Ohio

COLUMBUS, OHIO, Sept. 16—The price of gasoline in Columbus and central Ohio territory has been reduced from 22 to 21 cents per gallon. It is expected that the price will be still farther reduced in the near future.

Ky. Crops to Boost Car Sales

Corn Yield Expected to Equal 1915 Record—Tobacco and Hay Do Well

LOUISVILLE, KY., Sept. 16—Kentucky automobile manufacturers, distributers, dealers and factory representatives are elated over the latest report of the United States Department of Agriculture, forecasting for the State a corn crop of more than 114,000,000 bushels, which is equal to the crop of 1915, the largest ever raised in the State; a tobacco crop of 472,000,000 lb., which is 115,000,000 lb. larger than the crop of last year, and is a new high record, and a hay crop of 1,240,000 tons, an increase of 15,000 tons over 1915, and also a new high record. Crops falling short of 1915 include wheat, with an estimated production of 8,190,000 bushels as compared with 9,900,000 bushels in 1915; oats with a yield of 4,540,000 bushels, a decrease of 920,000 bushels from 1915, and apples, with a yield of 2,470,000 barrels as compared with 4,170,000 barrels in 1915. The large crops of corn, tobacco and hay more than offset the decreases in the other crops and the sharply advanced prices for all farm products give the crops of the State a substantially higher value than the crops of 1915.

This means prosperity in the Blue Grass State, and there is no question but what big corn, tobacco and hay crops

will result in a greater demand for cars. Farmers and people out in the rural districts are buying more machines than ever before.

It is pointed out by local automobile men that in a crop year marked by extreme fickleness of weather, from which the country as a whole has suffered severe losses in the principal crops, Kentucky has been conspicuously fortunate.

Skinner a Manufacturers' Representative

NEW YORK CITY, Sept. 16 — Kenneth Skinner has resigned as secretary of the Micro Piston Ring Co., this city, having sold his interest in the concern. Mr. Skinner has gone into business as a manufacturers' representative under the firm name Auto Appliance Co., 1960 Broadway, where he represents the G. H. Dyer Co., Cambridge, Mass., and the Asbestos & Rubber Works of New Jersey, Camden, N. J. The Auto Appliance Co. is also planning other connections.

Electric Charging Station in Melbourne

MELBOURNE, AUSTRALIA, Aug. 26.—The municipal electric supply department in this city will open a charging station for electric vehicles at its power house on Spencer Street. This station will be open day and night. The cost of current for charging will be 2 cents per unit between the hours of 10 p. m. and 8 a. m., and during other hours will be 3½ cents per unit. A charge of $2.43 per vehicle per week will be made for accommodation.

The absence of electric vehicles from the streets of Melbourne is largely due to the lack of charging stations, and the establishment of the above station will do much to create a demand for American electric vehicles of all kinds.

Barley Cars Painted to Suit Buyer

STREATOR, ILL., Sept. 16—The Barley Automobile Mfg. Co., Streator, has decided to paint all of the cars manufactured in the future in accordance with the wishes of the buyers. A lengthy list of color combinations has been prepared which is submitted to patrons.

Cleveland Dealers to Protect Buyers

CLEVELAND, OHIO, Sept. 16—Cleveland dealers have formed an association for the protection of automobile buyers, offering a uniform service policy. This policy will insure to the purchaser the service to which he is entitled, a strict fulfillment of the manufacturer's guarantee, inspection and adjustment.

Ceylon Import Duty Increased

COLOMBO, CEYLON, Aug. 20—The duty on automobiles, excluding trucks, imported into this country has been increased to 33 1/3 per cent ad valorem, the increase being effective Aug. 2. The former rate on automobiles was 5½ per cent ad valorem.

May Revive Hoosier 500-Mile

Proposed Increase of Purse to $50,000 May Mean Longer Distance

INDIANAPOLIS, IND., Sept. 16—It is expected that the Indianapolis Speedway will ask a sanction for a race of 500 miles with a purse of $50,000 to be held next Decoration Day. The original speedway contest was for this distance, but it was reduced to 300 because of the seeming unpopularity of the longer event.

Some time ago the speedway managers agreed not to offer more than $100 per mile and since a purse of $50,000 is being considered by the Indianapolis management, it necessarily follows that the distance must be increased if the $100 per mile agreement is to be kept.

22 Entries for Astor Cup

NEW YORK CITY, Sept. 19—Twenty-two entries have been received so far for the Astor Cup Race which will be held on the Sheepshead Bay track on Sept. 30. The entries are:

Car	Driver	Car	Driver
Crawford	Moore	Sunbeam	Christaens
Crawford	Klein	Sunbeam	Chevrolet
Crawford	Chandler	Deusenberg	Milton
Kleinart	Unnamed	Deusenberg	D'Alene
Delage	Franchi	Mercer	Pullen
Delage	Devigne	Mercer	Ruckstell
Dans L'Argent	Muller	Deusenberg	Buzane
Deusenberg	Devlin	Blue Bird	Unnamed
Peugeot	Resta	K. W. P. Sp.	Packard
Hudson	Vail	Olson	Unnamed
Adams Sp.	Adams	Olson	Unnamed

In addition the management expects further entries which will bring the list up to thirty-two.

Speedway Men Meet Sept. 29

NEW YORK CITY, Sept. 18—Representatives of speedways in Tacoma, Indianapolis, Chicago, New York, Cincinnati, Providence, Des Moines, Omaha, Kansas City and Sioux City will meet in this city Sept. 29 to fix the speedway racing dates for 1917. Some of these tracks are represented by three or four men, which brings the gathering up to twenty-five or thirty.

Returned Soldiers to Build Roads

TORONTO, ONT., Sept. 16—The Dominion Military Hospitals Commissions, which met in Toronto, to-day, under the presidency of Senator Lougheed, adopted resolutions advocating the building of a national highway by the Federal Government and the promulgation of a comprehensive land settlement policy for returned soldiers. The first resolution set forth: That as a considerable number of the men who have enlisted and are at present overseas or about to proceed thither, are unskilled laborers for whom it may be difficult to provide employment immediately on their return, the commission advocates the building of a national highway by the Federal Government. It would respectfully submit to the government that such an undertaking would be a work of the greatest value. Among the advantages would be:

1. Temporary employment would be provided for thousands of men who would not otherwise find work.
2. No public would provide so large an amount of employment at so small a capital outlay.
3. The highway would be of immense value as a means for the transit of agricultural and other produce.
4. It would be the means of attracting numbers of tourists, entailing the spending of money within the borders of Canada.
5. It would solve the problem of demobilization, as it would allow of a gradual disbanding of the troops from coast to coast.
6. It would be a most practical memorial to Canada's part in the great war.

Bearings on British Embargo List

LONDON, ENGLAND, Aug. 26—Ball and roller bearings and steel balls and rollers for bearings have been added to the British list of goods the exportation of which is prohibited to all destinations.

Spark plugs have also been included in the embargo list but these are prohibited from being exported to all foreign countries in Europe and on the Mediterranean and Black Seas, other than France, Russia (except through Baltic ports), Italy, Spain and Portugal.

Illinois Dealers Must Use Number Plates on Demonstrators

BLOOMINGTON, ILL., Sept. 16—Illinois automobile dealers must attach a license plate to every car used for demonstrating purposes, or which are otherwise engaged for commercial purposes. This announcement was made by Ben Cochrane, State examiner for chauffeurs who is now going over the State, issuing licenses to all drivers. In some cities, the dealers have purchased one license and utilized but the single plate. The courts have ruled that one license is sufficient but each car must carry a number. The duplicate plates will be furnished by the Secretary of State for their exact cost. Each dealer is being notified of the requirements of the law, and the authorities in each city have been directed to see that all dealers respect it.

400,000 Cars in Iowa?

DES MOINES, IOWA, Sept. 16—Iowa will have 400,000 automobiles, or one for every six persons in the State, according to the prophecy of W. D. Wilwerscheid of St. Paul, Minn., who manufactures automobile number plates. The registration for this year is already 190,000, and the total is expected to exceed 200,000 before the end of the present year.

84,000 See Show at Milwaukee

State Fair Included 202 Gasoline Cars, 2 Electrics and 14 Trucks

MILWAUKEE, WIS., Sept. 16—More people saw the second annual motor show of the Milwaukee Automobile Dealers, Inc., at State Fair park this week than visited the Milwaukee Auditorium show last January. Nearly 84,000 people paid 10 cents to see the Wisconsin State Fair automobile show of 1916. In all, nearly 100,000 people were admitted to the concrete automobile building. The official attendance at the fair for the week was 172,500, indicating that approximately one-half of the total number of visitors to the fair paid to see the show, and more than two-thirds of the persons who entered the big fair park actually saw it.

A total of 202 passenger cars; two electric cars; fourteen motor trucks, and thirty-one accessory exhibits were crowded into Automobile Hall this year.

Dealers of note from many parts of the country came to Milwaukee this week to inspect the exposition and get a line on the reasons for the great success achieved by the Milwaukee dealers' association in conducting a show at a State fair. Since the motor car became a factor, it has been exhibited at State and county fairs, generally under canvas, or in an open shed, not far from cattle and sheep, or in some corner of the fair grounds not needed for something else. It was the same at the Wisconsin State fair until 1915, when the M. A. D. leased a great concrete, shed-like "Machinery Hall," spent several thousand dollars in walling in the four sides with steel and glass, and leased out space to its members and other tradesmen on the same basis as it did for the annual show held in the Auditorium.

When the fair was over and the show closed its doors, there was enough left from the small admission charge so that every member of the association could receive a percentage return on his expense. Not only that, but every exhibitor was more than satisfied that his expenditure was well worth while on the basis of sales actually made and agencies actually placed.

Although not scheduled to open until Monday, Sept. 11, at 10:30 a. m., the show was ready for inspection at 2 o'clock Sunday afternoon. This year's fair was a 7-day event, instead of running only 5 days, as in former years.

$3,200 for Roads

On Wednesday, which was State and Good Roads day, the M. A. D., as previously pledged, turned over the entire receipts of the show to the Good Roads Association of Wisconsin, to further highway improvement propaganda. It is said that more than $3,200 was realized in this manner.

The booster tour took care of practically all the advance work of the association. It called the attention of from 750,000 to 1,000,000 people to the State fair automobile show.

—

30,000 Automobiles at Iowa Fair

DES MOINES, IOWA, Sept. 16—Over 30,000 automobiles, valued at about $200,000,000, passed through the gates of the Iowa State Fair during the 10 days of that recent event. Over 5000 cars entered the grounds daily on several of the big days of the fair, and ten men were working at top speed to take care of the car entrances during the rush hours. The fair this year, with a total attendance of over 300,000, was the greatest in the history of the State.

—

Car Show Building at Brockton

BROCKTON, MASS., Sept. 18—A $25,000 automobile exhibition hall is to be erected on the Brockton Fair Grounds. It will have display space for 108 cars, and will be completed the latter part of September. It will be 200 by 125 ft., with only two rows of posts, and will be electrically lighted.

Automobile Hall, in which the Milwaukee dealers held their exhibit at the State Fair

Giant's Despair Climb Oct. 7

A. A. A. Sanctions Revival of Classic—Eleven Events Based on Car Prices

WILKES-BARRE, PA., Sept. 18—The Giant's Despair Hill Climb will be held Oct. 7, according to the A. A. A. sanction.

The events are based upon the selling price of the cars entered, and are: 1, under $800; 2, under $1,200; 3, under $1,600; 4, under $2,000; 5, under $3,000; and 6, under $6,000; 7, Class E, nonstock, open to Class C cars with less than 230 in. displacement; 8, Class C, nonstock, division 6C, 231 to 300 in.; 9, Class C, free-for-all; 10, members of the Wilkes-Barre Auto Club, cars costing under $1,600; and 11, cars owned by members of the Wilkes-Barre Club, costing more than $1,600.

—

Omaha to Have Closed Car Salon in October

OMAHA, NEB., Sept. 20—A distinctly new departure is the closed automobile salon, first to be held in the country at Omaha during the latter part of October, and intended to become an annual event, the same as the regular automobile show, usually held in February, with which it will not conflict. It will be held in the main aisle of the main Brandeis Stores building, and will include the display of some forty closed cars.

If possible the salon will be kept open during the evening. It is planned to continue it for 3 days. Arrangements are in charge of a committee of three, headed by Clarke G. Powell.

—

N. Y. C. Sets Aside Parking Space, Due to Strike

NEW YORK CITY, Sept. 16—Special parking space has been provided in downtown New York for the large numbers of automobiles now being used by business men in reaching their offices, owing to the lack of transportation facilities caused by the traction strike. The following spaces have been set aside to meet these temporary conditions:

State Street, around park curb.
Battery Place, up to park curb.
Wall Street, Pearl to South Street, one line in center of street.
Burling Slip, Water to South Street, one line in center of street.
West Street, Rector to Cortlandt Street, two lines along outer edge of marginal way.
West Street, Christopher to Gansevoort, two lines along outer edge of marginal way.
Twelfth Avenue, Twenty-fourth to Thirtieth Street, two lines along outer edge of marginal way.
Fifty-seventh Street, Eighth to Eleventh Avenue, two lines in center of street.
Fourteenth Street, Fourth Avenue to Broadway, inside police stanchions on south side of street.
Fourth Avenue, Sixteenth to Seventeenth Street, vehicles to be backed up to west side of park curb.
Fourth Avenue, north of Fourteenth Street, vehicles to be backed up on west side to railing around monument.

Blevins and Davis in Merger

$500,000 Deal Combines Studebaker Dealers—New Co. Has Six States

CLEVELAND, OHIO, Sept. 16—The Blevins Auto Sales Co., Toledo and Cincinnati, and the A. R. Davis Motor Co., Cleveland, both Studebaker dealers, have been merged into a new $500,000 company headed by Harry W. Blevins. The company has contracted for $12,000,000 of Studebaker cars and will have the distribution of Studebakers in Ohio and portions of five adjoining States. The company starts with three buildings, in Cleveland, Cincinnati and Toledo. Associated with Blevins, who is president of the new company, are Vice-President A. R. Davis, Cleveland; Treasurer J. O. Hahn and Secretary H. G. Rossiter, Toledo. Davis was at one time branch manager for the Studebaker corporation and up to this time Hahn has been Cleveland branch manager.

Harry Newman Resigns

CHICAGO, ILL., Sept. 19—Harry Newman, president of Harry Newman, Inc., Chalmers dealers in Chicago, Milwaukee and Springfield has resigned to take a factory position. S. E. Comstock has been made general manager of the Chicago branch. Joseph B. Diebler will control the Milwaukee branch and J. D. Sullivan, Springfield.

Theft Insurance Rates Raised

BLOOMINGTON, ILL., Sept. 16—Increased rates for insurance against automobile theft have been decided upon by the Western Automobile Underwriters. The lower-priced cars, which are in greater danger of theft, due to difficulty in identification, have been raised from $2.75 to $5. On cars valued at $700 to $1,200 the rate has been increased from $2.25 to $3.50. The rate on cars valued at $1,200 to $2,100, has been raised from $2 to $3, while on the higher-priced cars, the advance has been from $1.75 to $2.

Capital-to-Capital Car in Detroit

DETROIT, MICH., Sept. 16—The capital-to-capital touring Hupmobile reached this city to-day to pay its respects to the originator of the tour, President J. Walter Drake of the Hupp concern. The party left Lansing, the capital of Michigan, and the sixteenth visited so far by the car, early in the day, and was met just outside of Detroit by a large party of good-roads enthusiasts, who formed a guard of honor, and, escorted by a band, brought the touring car through the downtown streets of the automobile metropolis and out to the Hupp factory. Detroit marks the end of the first division of the long hike. It means that the car has now traveled 3050 miles of the 20,000-mile trip it has undertaken with the intention of visiting every State capital in the interest of good roads. The car left Washington, D. C., the starting point, on Aug. 28.

Locomobile Holds Fourth Sale

NEW YORK CITY, Sept. 18—The Locomobile Company of America is holding its fourth semi-annual exchange car show and sale this week at its New York branch. The branch salesroom on West Sixty-first Street is devoted entirely to exchanged and rebuilt Locomobiles.

Ohio to Drive Out Motor Leagues

COLUMBUS, OHIO, Sept. 16—State Insurance Superintendent Frank Taggart declared he would start at once the task of driving out of Ohio all of the motorists' leagues and organizations which sell with their membership psuedo insurance policies which provide, besides membership in the organization, monetary compensation in case of accidents, free legal advice, free legal defense and many other attractive features.

Judge Taggart ruled these organizations are doing an insurance business without complying with the insurance laws of the State, and as such are illegal and their agents are subject to prosecution.

Arrested as Tire Swindlers

AKRON, OHIO, Sept. 16—Carl F. Geyer, manager of the Double Service Tire & Rubber Co., here, and manager of two other tire concerns, and Ralph C. Harper, assistant manager, were placed under arrest here by Federal authorities on a charge of using the mails to defraud.

Geyer and Harper are charged with doing a fraudulent mail order business, and Federal authorities said they had sold hundreds of defective tires, representing them as standard quality.

The arrests are the result of a year or more of investigation here by Federal officers and automobile clubs of Northern Ohio.

Geyer and Harper also are alleged to have been receiving tires for repair without returning them. They sold stock in the company for 25 cents and guaranteed buyers 80 per cent dividends, according to Federal officers.

Velie Represented in Australia

MOLINE, ILL., Sept. 16—The Velie Motor Vehicle Co., this city, has closed with Andrew Robertson, representing Clutterbuck Bros., Sydney, Australia, for representation of the Velie line in that country.

J. W. Packard a Packard Dealer

Buys Buffalo Branch of New York Co.—Will Also Handle Liberty

BUFFALO, N. Y., Sept. 18—J. W. Packard, who founded the Packard Motor Car Co., Detroit, Mich., and who gave his name to the car, has re-entered the automobile industry. He has purchased the Buffalo interests of the Packard Motor Car Co. of New York, and will conduct the Buffalo branch as an agency, handling the Packard and the Liberty. Mr. Packard is president of the new business, which is called the Packard Buffalo Motor Co., Inc. B. C. Day, former manager of the branch, is vice-president, and the other directors are: W. D. Packard, capitalist, a brother of the president; E. C. Sutton, president of the Wheat's Ice Cream Co., and L. R. Davidson of the Davidson Ore Mining Co.

The first Packard car was built in Warren, Ohio, by J. W. Packard, in 1899. While the business was still in its infancy Mr. Packard sold his interest to the group which now controls it, and has not been actively connected with the industry since.

The Packard Motor Car Co. of New York has opened a branch in White Plains.

Iowa Denby Dealers Meet

DES MOINES, IOWA, Sept. 16—Iowa dealers for the Denby Motor Truck were assembled here during State fair week, and at their convention listened to talks by Garvin Denby, president of the company, and W. J. Aitken, sales manager, who came from Chicago for the event. President Denby predicted a big business ahead in Iowa for the motor truck men, both among farmers and merchants.

Abler Opens Office in N. Y.

NEW YORK CITY, Sept. 18—M. M. Abler, manufacturers' representative, with branches in Amsterdam, Holland, Birmingham, England, and Soerabaya, Java, has opened a New York office at 32 Union Square East. The concern is now representing Studebaker cars, Goodyear tires, the Automobile Supply Mfg. Co., Brooklyn, N. Y., and intends other connections.

Bearings of Pa. Branch in Chicago

PHILADELPHIA, PA., Sept. 16—The Bearings Co. of Pennsylvania, this city, will open a branch in Chicago. Louis C. Smith, formerly associated with the Class Journal Co. in Chicago, will be manager.

Factory Miscellany

Standard Tire Plant Progresses—The new unit of the plant of the Standard Tire & Rubber Co., Willoughby, Ohio, is almost completed. It contains a power plant sufficient to turn out 1500 to 1800 tires per day. Equipment has been ordered. The company is now bringing out a black tread tire guaranteed to run 3500 miles.

Atterbury Rebuilds—Atterbury Motor Car Co., Hertel Avenue, Buffalo, N. Y., is rebuilding its factory recently destroyed by fire. The estimated cost of the new factory is $50,000.

Tire Plant for Belleville—Maple Leaf Tires, Ltd., has secured a factory site of 22 acres in Belleville, Ont., and has commenced building operations. The company will employ 100 hands at the start. The main building will be nearly 300 ft. long and of concrete and steel construction. It is intended to rush it toward completion before cold weather sets in. Fifty men are now at work preparing for the foundation.

Overland Service Plant in Brooklyn—The Willys-Overland Co. has leased a site 150 by 130 at St. Marks and Underhill Avenues, Brooklyn, N. Y., on which it will erect a service plant. The rental for a period of years is $100,000.

Hudson Service Plant in N. Y.—The Hudson Motor Car Co. of New York, Inc., has let the contract for a service station, 203 by 239, four stories, between West Sixty-eighth and West Sixty-ninth Streets and the North River.

Tom Thumb Tractor Grows—The Tom Thumb Tractor Co., University and Thirtieth Avenues, S. E., Minneapolis, Minn., plans increasing its facilities to twenty-five tractors per day by April 1, 1917. The plant now makes ten tractors per week and employs about thirty men. This number may be increased to 200.

Harrow Spring Adds—The Harrow Spring Co., Kalamazoo, Mich., is to build a large addition to its plant.

Christensen to Expand—The Christensen Engineering Co., Milwaukee, Wis., which has increased its capital stock from $300,000 to $1,000,000, will immediately increase its output of the Christensen air-starting mechanism. The starter is generally used on fire department cars, aeroplanes and motor trucks, many having been shipped to Europe in the last 18 months for war purposes. The factory at 841 Thirtieth Street will be enlarged and from 75 to 100 men added to the payroll.

Boone County Tire Buys Site—The Boone County Tire and Rubber Co. has been organized and will shortly commence the manufacture of tires at Belvidere, Ill. Ten lots have been purchased in a suburb of that city and plans have been prepared for the necessary buildings. When in operation, the plant will turn out 200 tires per day and will employ from 150 to 200 persons. It is hoped to have the buildings erected and machinery installed by Jan. 1.

Parker Rust Proof to Build—The Parker Rust Proof Co., Detroit, Mich., which will manufacture a rust-proof liquid used on motor cars, has purchased a site on Conant Road, in Hamtramck, for a factory, work on which has already been started. It is stated that 700 men will be employed in the plant.

Big Four Tire Plant—The Big Four Tire and Rubber Co., Cleveland, Ohio, has purchased as temporary quarters the plant of the Ohio Rubber Co. on the Lake Shore and Big Four tracks at Berea for about $12,000. There are 18,000 sq. ft. of floor space in the plant, which occupies a tract of 5½ acres. The company is moving its machinery into the building and expects to begin manufacturing in about 60 days. The company is to manufacture a patented combination rubber, fabric and steel tire.

United Smelting's New Mills—The United Smelting & Aluminum Co., Inc., New Haven, Conn., has opened its new rolling mills in that city. Work is furnished in aluminum sheets, coils, circles, etc., to any specifications.

Miller Has Factory Paper—The Miller Rubber Co., Akron, Ohio, is issuing a factory paper entitled "Miller Talk," every one of the 3000 employees being asked to contribute.

Firestone Opens in Kansas City—The new branch building of the Firestone Tire and Rubber Company in Kansas City, Mo., was opened Sept. 14, and a dealers' convention was held during the day, which was attended by 500 dealers from various points in the branch territory.

The new building is eight stories high, and contains shop, storage and shopping facilities.

The dealers spent part of the morning inspecting the new quarters and meeting the various Firestone executives from the home office in Akron. The day's events included a group photograph, luncheon, motor parade, business session, in which sales and distribution problems were discussed, and ended with a banquet in the evening.

The Automobile Calendar

ASSOCIATIONS

Sept. 25—Indianapolis, Convention for Formation of Indiana Automobile Trade Assn., under auspices of N. A. T. A., Hotel Claypool.

Oct. 2-5—St. Louis, Fall Meeting Assn. of Automobile Accessory Jobbers.

TRACTOR

Oct. 14-29—Dallas, Tex., Demonstration, Texas State Fair.

The Week in the Industry

Picard & Stern Ford Dealers—A. J. Picard and E. Joseph Stern have opened a Ford agency at 1659 Broadway, New York City. Picard is the principal in A. J. Picard & Co., an accessory jobber and dealer and distributer of the Genemotor electric system for Fords. Stern is associated with Picard in the Picard company.

To Handle Scripps-Booth—Michigan distribution of the Scripps-Booth four and eight-cylinder cars has been secured by the newly-formed Oldsmobile Distributing Company, Detroit. Recently W. H. Collins and F. J. Muellerschoen bought out the Oldsmobile branch here, and the taking on of the Scripps-Booth adds another car to the line.

Howard Denneen's N. E. Sales Mgr.—S. B. Howard, formerly eastern and foreign representative of the General Motors Company, has been appointed New England sales manager of the Denneen Motor Company, Cleveland, Ohio.

E. P. Strang, formerly with the Kirk-Latty Mfg. Co., Cleveland, has been appointed middle western sales manager of the Denneen company.

Fisk Rubber Builds Service Station—The Fisk Rubber Company opened a new branch office and service station in Galesburg, Ill., leasing a new building, corner of Simmons and South Kellogg Streets. The Galesburg branch is one of a series being established throughout Illinois. The building has a frontage of 60 ft. and a depth of 80 ft. A vulcanizing department and repair shop will be inaugurated.

Earle and Boggs Open N. Y. Office—L. H. Earle and G. A. Boggs, who resigned from the Continental Motors Company last July, have incorporated as Earle & Boggs, to act as manufacturers' representatives for materials. Offices have been taken at 1790 Broadway, New York City, and accounts opened with the Pierce Governor Company and the Blood Brothers Machine Company.

King from Branch to Factory—Changes have been made at the New England branch of the B. F. Goodrich Co. at Boston by the promotion of officials to the factory. Edward King, for several years office manager, has been brought to Akron to join the administration forces. O. E. Hoeger, for some years office manager at St. Louis, has been moved to the Boston branch. C. E. Littlefield, who had charge of advertising and publicity at Boston, has been promoted to a position at Akron under E. C. Tibbetts. Mr. King was presented with a gold watch by his associates before leaving for Akron.

Storey Takes Maxwell in Canada—F. H. Storey, formerly an official of the Maxwell factory, at Detroit, Mich., has arrived in Winnipeg, Man., to take over the interests of the Maxwell Company of Canada, from Fort William to the Pacific Coast.

One of the first steps Mr. Storey will take will be the complete reorganization of the Maxwell service department in Winnipeg. Also there will be new showrooms of the type used by the Maxwell American firm during the New York-Chicago and Boston automobile shows last year, opened at 700 to 708 Portage Avenue.

Cleveland Retail News—The Jordon Motor Car Agency has been formed to handle the Jordon in Cleveland, Ohio, and space has been taken temporarily at 2052 Euclid Avenue. C. C. Neighbors, formerly of the Neighbors Motor Car Company, will be the manager, while V. E. Watkins will be sales manager. Their territory will consist of Cleveland and northeastern Ohio.

The Carris-Franklin Company, 1829 East Thirteenth Street, will handle the Franklin in Cleveland and adjacent territory. C. S. Carris has been associated with the Franklin organization for thirteen years. The employees of the service department of the agency all came from the Franklin factory.

The local sales office of the Standard Tire & Rubber Co., at Cleveland, has been moved from 5017 to 6521 Euclid Avenue. The executive offices remain in the Hippodrome Building.

J. Preston Penfield has been chosen president of the Luxurious Light Car Co., 1849 Euclid Avenue, Cleveland, to succeed J. M. Smith, who has gone to the Cole Sales Co. of Indiana.

E. D. Endsley has been appointed sales manager of the Alter Motor Car Company, distributer of Scripps-Booth and Liberty in Cleveland.

Gets H. A. L. in Ohio—A. W. Woodruff has organized the Woodruff Motors Co. and has opened offices and salesrooms at 2019 Euclid Avenue, having been appointed distributer of the H. A. L. for northern Ohio.

Edison Opens in Los Angeles—The Edison Storage Battery Supply Co. has opened its Los Angeles office on the fourth floor of the San Fernando Building, Fourth and Main Streets.

James F. Rogan, who has been acting as local distributer, will become resident manager.

H. A. L. California Distributers—The Eugene Schuler Co., San Francisco, Cal., has been appointed distributer for H. A. L. cars for the State.

Pearl Motor Car Co., Los Angeles, will have charge of the territory of southern California.

Mountain Trade News—The Colorado Motor Co., Denver, is the name of a new Reo distributing agency for Colorado, with headquarters at 1535 Cheyenne Place. The manager is George J. Hawley, formerly manager of the Reo-Saxon Auto Sales Co., Colorado Springs.

The William Thorney Auto Co., Denver, Apperson distributer for Colorado and Wyoming, has secured the Regal distributing agency for the same territory.

The Carter Motor Car Co., Denver, formerly the Overland Auto Co., which was Overland distributer for Colorado and Wyoming several years up to the recent opening of the Willys-Overland branch here, now has the King and Saxon distributing agency.

The Motor Bank, Denver, is the name of a bank just opened at 1245 Broadway, chiefly for the purpose of helping dealers finance their business when stocking up with cars.

The Roberts Auto Co., Denver, Marmon distributer for Colorado and Wyoming, is having a $20,000 building erected at 1231-1239 Broadway, on a $30,000 site. The building will be two stories high and 50 by 150 ft.

Heiser Brothers Co., Denver, Velie distributer for Colorado and Wyoming, has moved from 1236 Broadway into a new $38,000 building of its own at 700 Broadway. The new structure is 50 by 125 ft., one story and basement.

The Premier Motor Car Co. of Denver, is the name of a new $25,000 incorporation to distribute the Premier in Colorado, Wyoming and New Mexico. O. H. Woods is president and treasurer, and Charles H. Davis, formerly salesman for the Norton-Buick Co., is manager. The salesroom will be located in the Fisk Building.

The Cadillac Motor Co., Denver, Cadillac distributer for Colorado and Wyoming, is erecting a $40,000 fireproof building of steel, concrete and brick, on the corner of Broadway and East Fourteenth Avenue. It will be 50 by 133 ft., three stories and basement.

Cowl Board and Speedometer Combined—for Ford Cars

Here's a new Stewart Product for Ford Cars—a Cowl Board, beautifully finished in black enamel, with a Stewart Speedometer mounted in the center.

It adds a finish and a touch of distinction to the Ford dash.

And it holds the Speedometer in a position where it is easy to read.

And the price complete is only a trifle more than the single cost of the Speedometer.

Already selling fast in all parts of the country.

Get in among the leaders.

Speedometer for Fords, $10
Cowl Board, $1.25 Price Complete, $11.25

"It will pay you to see that the car you buy is equipped with Stewart Products"

Spicer Mfg. Co. Reorganized

$7,000,000 Corporation to Take Over Business—Name and Management Unchanged

PLAINFIELD, N. J., Sept. 26—The business of the Spicer Mfg. Co., probably the largest maker of universal joints in the world, has been purchased by a syndicate of bankers headed by Merrill Lynch & Co., New York, and Cassatt & Co., Philadelphia. The purchasing syndicate is now offering $1,500,000 first preferred 8 per cent stock at $100 per share. There will also be $500,000 second preferred and $5,000,000 common stock. The first preferred 8 per cent stock has the privilege of conversion into common stock at any time.

Officials Continue in Office

C. W. Spicer and the other officials who have been responsible for the remarkable success of this company will continue to occupy their present positions, in fact, the management will not be changed in any way.

Owing to the fact that Spicer universals are used by a number of the big quantity producers of automobiles, the demand in the past 2 years has increased enormously and the factory at South Plainfield has been expanded in order to take care of its customers. At the present moment a large extension is in process and it is said that the number of universals made during 1917 will not be less than 700,000. Of these, of course, a large proportion are sent out in pairs welded to driveshafts as complete units. Practically all the needs of the automobile industry are taken care of by nine different sizes of universals, this covering both passenger car and truck, so the business is a very straightforward one as a manufacturing proposition.

The reputation of the Spicer joint has been obtained mainly by the use of high grade material and careful workmanship of the wearing parts. A proper selection of the steel and accurate heat treatment are features of the business to which C. W. Spicer has given very particular attention.

—

Tainsh Mitchell Sales Manager

RACINE, WIS., Sept. 26—John Tainsh, formerly assistant sales manager of the Mitchell Motors Company, Inc., this city, has been appointed general sales manager, which position was left vacant by the election of O. C. Friend as president and general manager. George W. Hipple retains the office of general merchandising counsel, and there are three assistant sales managers, Frank W. Pelton, for 3 years in charge of advertising, adding to his duties those of assistant sales manager in charge of western sales; William Liniger, formerly Eastern field representative, becomes assistant sales manager of Eastern sales, and F. W. Archer sales manager in charge of distribution. Federico Sarda, at present abroad in the interests of the company, continues as foreign sales manager.

—

Plath to Handle Harroun Sales

DETROIT, MICH., Sept. 25—John J. Plath, who was sales manager of the Maxwell Motor Co., has resigned to join the recently organized Harroun Motors Corp., where he will have charge of the sales department.

No successor has been named yet by the Maxwell company to take Mr. Plath's place, who, previous to his promotion as sales manager of the company, was manager of the Maxwell branch in New York.

—

Roamer Price Increased $50

STREATOR, ILL., Sept. 26—The Barley Motor Co., this city, has increased the price of the Roamer car $50, making the new price $1,850.

$100,000,000 G. M. Corporation

New Organization To Take Over G. M. C.—1916 Profits 168.61% on Common

HIGH LIGHTS OF G. M. C. 1916 REPORT

Net Profits	$27,740,596
Gain over 1915	12,814,274
Gross sales	156,900,296
Gain over 1915	62,475,455
Cars built	132,088
Gain over 1915	56,020

NEW YORK CITY, Sept. 27—A new $100,000,000 company, to be styled the General Motors Corp., will on Nov. 1 take the place of the present General Motors Co. Holders of more than 65 per cent of the stock of the General Motors Co. have signified their consent to the readjustment and the plan will become effective Nov. 1, 1916.

The formation of the new company will have no effect whatever on the plan of operation of the various General Motors subsidiary companies, nor will there be any changes in personnel or management. Although it had been rumored that with the formation of the new company, the Chevrolet Motor Co. would be taken in, officials of this company state that mention of the Chevrolet company did not enter into the discussion.

Announcement of the readjustment plan follows publication of the General Motors Co.'s annual statement, as of July 1, 1916, which shows that the net profits for the fiscal year were $27,740,596, after deducting preferred dividends. This represents 168.61 per cent on the $16,511,783 common stock outstanding and compares with $14,926,322 net profit for the year 1915, an increase of $12,814,274.

Plan Formally Ratified

N. A. C. C. Forms Traffic Board

Committees of Traffic Managers and R. R. Men to Handle Freight Car Shortage

NEW YORK CITY, Sept. 26—A committee of four traffic managers, consisting of: H. R. Moule (Chalmers), Chairman; H. Higginbottom (Dodge), H. M. Newlin (Maxwell), and C. W. Eggers (Willys-Overland), has been formed to co-operate and confer closely with the Traffic Department of the National Automobile Chamber of Commerce on the question of freight car supply, and the department will put into effect any action that may be helpful.

A committee of five railroad operating men has also been appointed, consisting of: C. H. Bieber (Michigan Central), Chairman; H. J. Merrick (New York Central), C. B. Strohm (Santa Fe), J. W. Roberts (Pennsylvania Lines) and E. E. Betts (Chicago & Northwestern), to give the handling of automobile equipment special thought and co-operate with the chamber in proper supervision of the cars.

The N. A. C. C. has notified its members that car balances of the American Railway Assn. show a net shortage of 14,281 freight cars. This is the lowest supply ever reported at this time of the year when there is usually quite a surplus of cars. A year ago this surplus was 264,243 cars, notwithstanding which a serious car shortage was experienced during the months immediately following.

Members are told this condition indicates that each freight car must be made to perform maximum service and it is urgently recommended that incoming freight at the factories be unloaded promptly and not be permitted to accumulate; also that shipments of automobiles to dealers should be unloaded immediately upon arrival, inasmuch as such shipments are in the special automobile cars, which will be the first to feel the shortage of equipment.

—

N. A. C. C. Committees Named

NEW YORK CITY, Sept. 23—Following is the personnel of the various committees of the National Automobile Chamber of Commerce for the coming year:

Patents—Chairman, C. C. Hanch, Studebaker Corp.; William H. Van Dervoort, Moline Automobile Co.; Windsor T. White, White Co.; W. C. Leland, Cadillac Motor Car Co.; Howard E. Coffin, Hudson Motor Car Co.

Traffic—Chairman, William E. Metzger, Argo Electric; R. E. Olds, Reo Motor Car Co.; A. I. Philp, Dodge Bros.

Show—Chairman, George Pope; W. C. Leland, Cadillac Motor Car Co.

Legislative—Chairman, H. H. Rice; Waverley Co.; J. Walter Drake, Hupp Motor Car Co.; J. I. Farley, Auburn Automobile Co.

Electric Vehicle—Chairman, H. H. Rice, Waverley Co.; Fred R. White, Baker-R & L Co.; W. C. Anderson, Anderson Electric Car Co.

Commercial Vehicle—Chairman, Windsor T. White, White Co.; Alvan Macauley, Packard Motor Car Co.; H. Kerr Thomas, Pierce-Arrow Motor Car Co.; P. D. Wagoner, General Vehicle Co.; M. L. Pulcher, Federal Motor Truck Co.

Good Roads—Chairman, Roy D. Chapin, Hudson Motor Car Co.; W. E. Metzger, Argo Electric; C. C. Hanch, Studebaker Corp.

Hand Book—Chairman, Carl H. Pelton, Maxwell Motor Co.; A. I. Philp, Dodge Bros.; A. L. Riker, Locomobile.

Membership—Chairman, Wilfred C. Leland, Cadillac Motor Car Co.; Hugh Chalmers, Chalmers Motor Car Co.; C. W. Churchill, Winton Co.

—

Torbensen Axle Elects Officers

CLEVELAND, OHIO, Sept. 23—At a meeting of the stockholders of the Torbensen Axle Co., this city, V. V. Torbensen was elected president; W. J. Baxter, vice-president; J. O. Eaton, treasurer; and A. H. Ide, secretary. These officers, with S. H. Tolles, constitute the board of directors.

Besides the officials named, W. F. Rockwell has been appointed works manager; R. A. Bruce, sales manager; and C. I. Ochs, purchasing agent.

—

151,067 Overlands in Year

TOLEDO, OHIO, Sept. 23—The Willys-Overland Co. shipped 151,067 automobiles during the 12 months ending Sept. 19, of which 59,378 were small light cars. This is nearly double the record of the preceding 12 months when 80,750 cars were shipped. More unfilled orders for immediate shipment are on hand at present than there were a year ago.

—

Rosenberg is M & S Engineer

DETROIT, MICH., Sept. 22—R. H. Rosenberg, formerly with the Universal Machine Co., Bowling Green, Ohio, has resigned to become chief engineer with the M & S Gear Co., this city.

—

$5,000,000 Firestone Stock Sold

CLEVELAND, OHIO, Sept. 25—H. S. Firestone, president of the Firestone Tire & Rubber Co., closed negotiations, Sept. 22 for the sale of $5,000,000 new preferred stock issue of the company to the Cleveland Trust Co. The stock will be offered to the public soon.

This transaction is unusual in rubber financing as it is the first large issue to be sold carrying as low a dividend rate as 6 per cent. Previous issues have been on a 7 per cent basis.

The stock is callable at 110 and the redemption price will be at the same figure. Beginning in 1921 the company agrees to redeem the stock to the extent of 5½ per cent of the largest amount at any time outstanding. The present issue, $1,000,000 has been called for redemption at 110 as of Nov. 1. The new stock will be issued as of that date or earlier.

Goodyear Adds to Agents

No Exclusive Territory Given—Dealers Must Make Money and Give Service

AKRON, OHIO, Sept. 26—The Goodyear Tire and Rubber Co. will put into effect Oct. 1 a new plan for retailing its tires. The number of dealers will be reduced about 66 per cent, and those that remain will be required to be of high business calibre. All price lists will be withdrawn Oct. 1 and the new plan will be instituted at once.

Dealers under the new system must be a service station as well. They must carry an adequate stock of tires, tubes and accessories and must be in position to give to the public the service to which Goodyear considers the public entitled.

No Price Changes

There will be no change of consequence in price. Tires will be sold as heretofore on the consumers' list, and the dealer's price will be based upon what has become to be known as the pink list. No requirements as to price maintenance will be made. The only thing the company will insist upon is that the dealer so conduct his business that he is a worthy representative.

It is estimated that there are now in the United States 25,000 or 30,000 Goodyear dealers, and it is also estimated that under the new plan there will be only about 10,000. If the present volume of factory production continues it is obvious that the dealers under the new plan will do in the aggregate 200 per cent more business than they are doing now.

Plan Tried Out

The plan has been operating partially in Chicago, Kansas City, St. Louis, Boston and New York for several weeks. It was begun for the first time about three months ago. The present lists have not yet been withdrawn in these cities, but the placing of service dealers has been begun.

While the Goodyear move is radical among large tire producers, it is not entirely new with Goodyear for its cord tire has been handled on this basis. Because the cord tire was a new type and a comparatively expensive article, it was required that the dealer maintain a certain stock and be equipped to take care of his trade.

The new contracts with dealers will not give exclusive territory, although one of the company's executives states that in towns of a reasonably small population there might not be more than a

(*Continued on page* 551)

Kent Motors Car at $985

Four-Cylinder Touring and Roadster Models Planned—Buy N. J. Plant Site

NEW YORK CITY, Sept. 23—The Kent Motors Corp. has been formed here to manufacture a four-cylinder touring and roadster model at $985. A plant site has been purchased in Newark, N. J., and it is stated that a plant to produce 5000 cars a year will be started at once. Production of cars will be started about Jan. 1. The company will absorb the Kent Motors Corp. of New York, which heretofore has been a dealer, handling at various times the Pullman, the Abbott-Detroit and the Elcar; distribution of the Elcar will be continued for the time. F. H. Clarke, president of the old company, is president of the new one, and associated with him as directors are: Wallace A. Hood; Major A. White, president New York Plate Glass Co., president of the City of New York Insurance Co., and vice-president of Madison Trust Co.; Thomas L. Raymond, Mayor of Newark, N. J.; P. P. Dean, chief supervising engineer; L. A. D. Percival, president Amalgamated Paint Co., New York; R. J. Cosgrove, formerly of the Ford Motor Co.; Lloyd H. Foster, factory superintendent, formerly of the Hupp Motor Car Co. and Briscoe Motor Co.; and Alexander U. Conquest, formerly assistant engineer, Daimler Motor Works, England.

The car will have a Continental 3¾ by 5-in. engine equipped with Bosch magneto and Bosch lighting and starting and Zenith carbureter. Other specifications are: Borg & Beck clutch; Grant-Lees gearset; Timken axles; Gemmer steering gear. The wheelbase will be 116 in. on 32 by 4 tires and rear springs will be three-quarter elliptic. Equipment includes top, slanting windshield, Stewart speedometer, 8-day clock and the usual tools.

—

Canadian Ford Copies Selling Plan

WINNIPEG, MAN., Sept. 24—The Ford Co. of Canada has decided to adopt the selling plan recently started by the American company. In Centre Winnipeg, Michael Ert, Limited, will act as Ford selling agents and will immediately construct a new service station and garage in order to be in position to supply first class service. North Winnipeg will be controlled by the Universal Motor Co., a newly formed organization having behind it representatives of the brewing firm of Drewry's, Ltd., on part of whose property the new garage and service station will be erected.

West Winnipeg will be under the control of Dayton and Studely, former members of the factory branch sales staff. This firm is also erecting a new service station and show rooms.

A garage and service station will also be opened in the South Winnipeg district, but the name of the firm securing the agency has not yet been announced. Any of the agents can sell in the other man's territory, but the service stations will only be expected to cover the districts as outlined. The entire sales staff of the factory branch has been closed and most of the members of the staff have secured positions with the new selling organizations.

Dealers Give Bonds

A bond has to be given by all of these dealers protecting the interest of other agents in regard to any price cutting, retail sale prices of the Ford as advertised having to be maintained in every instance.

—

Automobile Securities Corp. Formed

NEW YORK CITY, Sept. 23—The Automobile Securities Corp. has been incorporated here with $100,000 capital to deal in automobiles, accessories, etc. The incorporators are: C. R. Allison, P. Lacroix and W. L. Glover, New York.

—

Crow-Elkhart Motor Co. Now

INDIANAPOLIS, IND., Sept. 25—The Crow Motor Car Co., Elkhart, Ind., was granted permission by court order last week to change its name to the Crow-Elkhart Motor Co. The name of the car manufactured by the company recently was changed to the Crow-Elkhart.

—

Sweet Leaves M. & A. M. for U. M.

NEW YORK CITY, Sept. 25—William E. Sweet, for 10 years general manager of the Motor & Accessory Manufacturers, the national organization of the accessory industry, has resigned to become assistant to the president of the United Motors Corp., New York. This organization is a holding company recently formed and its subsidiaries are Delco, Hyatt, New Departure, Remy, Klaxon and Perlman. Mr. Sweet assumes his new position on Oct. 15, and will have offices at 33 West Forty-second Street, this city. He will have the management of the corporation under the direction of the president and board of directors. Mr. Sweet was directly responsible for the organization and development of the accessory association and his new position should give him good opportunity for development work. A. P. Sloane, Jr., of the Hyatt company is president of the corporation, E. A. Deeds, of Delco, vice-president, and Dewitt Page of New Departure, secretary-treasurer.

Another Record for Hudson

Makes Transcontinental 'Frisco-N. Y. Round Trip in 10 Days, 21 Hr., 3 Min.

SAN FRANCISCO, CAL., Sept. 24—The Hudson Super-six which arrived in New York, Sept. 18 after shattering the record for the trip from San Francisco to New York by 15 hr. has returned to San Francisco, the elapsed time for the round trip being 10 days, 21 hr. and 3 min. The elapsed time between New York and San Francisco was 5 days, 17 hr. and 32 min. as against 5 days, 3 hr. and 31 min. for the journey eastward.

Remaining in New York only long enough to replenish gasoline and lubricating oil and give the drivers a chance for some rest, the car was started back to San Francisco on Sept. 18 at 10.50 p. m. It was checked out of New York by Jas. A. Hemstreet of the American Automobile Assn. who checked it in on its eastward journey.

Drivers the Same

The same drivers had the car in charge in its second transcontinental dash, Ralph Mulford, A. H. Patterson and C. H. Vincent alternating at the wheel.

The total distance traversed was a trifle less than 7000 miles (6952), and the average daily mileage was about 700.

On the return journey heavy rains were encountered which caused the drivers to go through the Sierra Nevada mountains, thus increasing the distance. But for this, the time, according to the drivers, would have been about 15 hr. less. The last stretch to the Pacific Coast required 35 hr., whereas the same distance was covered in the eastward journey in 20 hr.

—

Chandler Export Office Moves

NEW YORK CITY, Sept. 23—W. S. M. Mead, vice-president of the Chandler Motor Car Co. in charge of exports, has removed his offices from the salesrooms of the Brady-Murray Motors Co., New York distributors, to larger quarters at 1790 Broadway. C. S. Levitt, formerly traffic manager of Gaston, Williams & Wigmore, has joined the Chandler export staff to look after its rapidly increasing foreign shipments.

—

3½-Ton Acme on the Way

CADILLAC, MICH., Sept. 19—The Cadillac Auto Truck Co., will shortly bring out a new model. This will be a 3½-ton truck, the largest yet made by this concern. Full particulars are not yet available.

BRAZIL

Largest Country in South America Is Not Greatest Automobile Market—Poor Roads Big Handicap—State of Sao Paulo, with Its Coffee Industry, Is Best Field for U. S. A. Automobiles, Trucks and Tractors

Part I

By David Beecroft

¶EDITOR'S NOTE:—This is the first of a series of articles embodying the close observations of automobile and general trade conditions in Brazil made by Mr. Beecroft, Directing Editor of THE AUTOMOBILE, during a 10-weeks' trip through Argentina, Uruguay and Southern Brazil as a delegate of the United States Government and member of the Argentine Return Visit Committee. Future articles will further analyze the possibilities of selling cars, trucks and tractors in the United States of Brazil.

BRAZIL does not offer the great automobile market possibilities to-day that Argentina does. Last year we exported over seventeen times as many cars to the Argentine Republic as to Brazil. This is an unexpected condition, in that Brazil is much larger in area than Argentina—Brazil is as large as all U. S. A., leaving out Alaska, whereas Argentina is equal in area to that part of our country east of the Mississippi River. But go further: Brazil has a population of 25,000,000 and Argentina has only 8,000,000. Automobile buying capacity cannot be gaged by area or population.

Will Be Great Market

Brazil will one day be a great buyer of U. S. A. cars; it may be a greater buyer than Argentina, but for the present the reverse holds good. Last year we exported 4444 automobiles to Argentina and only 253 to Brazil. These figures do not represent the correct purchasing ratio between the two countries. The Argentine figures are partly due to war prices for grain and beef, the two great products of Argentina. Our automobiles have been selling to Argentine farmers, who might not have taken to them so readily had it not been for the unexpected cash that flowed from Europe.

Brazil was not so fortunate. She is not the great grain-producing nation that Argentina is. She is not so great a cattle-raising nation. Her goods were not so much in demand. These are not the only reasons that have made Brazil such a poor buyer. There are several others that cannot be answered in a word, or in one article.

The U. S. A. automobile and truck and accessory maker are more interested in Argentina than Brazil for varied reasons. It is debatable if the population of Brazil is as potential a buying population as Argentina's. Argentina is much more white in population than Brazil. There is much African blood through all parts of Brazil, with the possible exception of one or two States along the Atlantic south of Rio de Janeiro. The Atlantic seaboard and southern Brazilian States are the only ones that greatly interest our manufacturers, although there are some ports in the Amazon valley that are absorbing numbers of our cars. The valley of the great Amazon is the largest area in the world that has not come under the sway of man as it should. It is very backward. It is an exceedingly difficult area to handle due to the climatic conditions, in places it lies directly under the equator. The population is very largely colored. It is generally conceded as a poor place for white men.

There is another difficulty, namely, the wide river beds of the Amazon and its many tributaries, which are often overflowed for miles on either side, rendering cultivation very difficult. Because of this situation it is to the southern part of Brazil that our makers must to-day turn their attention.

In this southern section there is no better place than the State of Sao Paulo, the great coffee land of South America, and as fine a part of South America as can be found. Sao Paulo is a white State, with white labor on the coffee plantations. The people in the hustling City of Sao Paulo are white. They are as honest people as you can find. They have a complete grasp of modern business methods. Their fair city and productive state bristle with twentieth-century ideas. You can find no better territory south of the equator. It is a place of greatest interest to our entire automobile and farm-tractor industry.

Before going into details of the automobile selling market in Brazil it is better to gain a clearer conception of the state in general. The map on the opposite page will assist.

Brazil as a Country

The country is known as The United States of Brazil. Brazilians are as proud of the title as we of ours, The United States of America. They do not like our title, because South America is as much America as North America. They say we should style ourselves The United States of North America. A person from any country in South America is as much an American as one from North America.

In area Brazil is as large as we are, but in population only one-third. The country is divided into twenty-one States—just as we are divided into forty-eight. We have our federal capital in the District of Columbia, and in Brazil the federal district is called Rio de Janeiro, and in it is located the federal capital, the City of Rio de Janeiro. As with us each State in Brazil has its State capital and there are the two legislative houses, the House of Representatives and the Senate. The map shows the division into the different States and the capital of each State is given.

The Atlantic seaboard from Natal to Rio Grande do Sul gives every indication of progress. The network of rail-

The United States of Brazil

THE United States of Brazil, a federation of twenty-one states each with its own government, occupies the largest part of the continent of South America. In area Brazil compares with the United States of America, the Dominion of Canada, the continent of Europe and the continent of Australia. Each occupies approximately 3,000,000 square miles. In population Brazil ranks much higher than Australia or Canada but not so high as Europe or U. S. A. Brazil has 25,000,000, Canada has approximately 8,000,000 and Australia has 5,000,000.

Each of the twenty-one states comprising the United States of Brazil has a house of representatives and a senate, both being elective bodies. The map shows the names of all twenty-one states and the capital city of each is marked. There are scores of smaller cities in each state but they are not indicated.

The part of Brazil in which U. S. A. automobile, truck, accessory and tractor makers are most interested is that section along the Atlantic coast from the mouth of the Amazon river to Uruguay. The line of ports shows that settlement started from the coast. All of these ports have very modern docks with electric or hydraulic cranes for loading and unloading. We have no docks in U. S. A. that in general can compare with them.

From these ports railroads pierce the interior, those radiating from the great coffee port of Santos being the most extensive. These railroads are generally held by Europeans, England being by far the largest controlling interest. Brazil does not compare with Argentina in railroad mileage, but good progress is being made in pushing her roads.

This section of Brazil covered by railroads is the greatest buying center for automobiles. The northern part of Brazil is accessible by the great Amazon river and its large tributaries. The Amazon is navigable for steamboat lines from New York for over 2000 miles; in fact, you can take a steamer in New York and sail entirely across Brazil on the Amazon. You can reach Peru this way. Then several of the Amazon tributary rivers on the south are navigable for much of their length.

roads is a good indication of the relative importance of the different sections. The State of Sao Paulo has most railroads; it is the coffee land. The great State of Minas Geraes has many railroads to serve its valuable mining interests, the State being the greatest mineral area of Brazil.

All along the coast you will observe that railroads radiate from the ports, but as yet the line of ports has not been linked together by railroads. Thus as yet you cannot travel from the Port of Bahia to Rio by train. Connecting railroad lines are under construction, but it may be several years before all connections are completed. The same is true between Bahia and Pernambuco. Both of these are large cities, Bahia with 300,000 population and Pernambuco with 200,000 people. Their population would warrant them being connected, but the percentage of African blood exerts a curtailing influence.

Few Long-Distance 'Phones

There are many other things in connection with Brazil that surprise you. Thus you cannot talk by long distance telephone from Rio to Sao Paulo, 310 miles, the two greatest cities in the country. Both cities have excellent telephone systems and both have lines radiating out from them for miles, but as the two cities are in separate States it will require federal legislation to let them be connected up. Business is much hampered because of this. Rio is not only the political capital, but the business capital of the country and should be in long-distance telephone communication with the other great cities. There are good telegraph lines and the rates are reasonable.

In contrast with this in the State of Sao Paulo, which is as large as all our six New England States with New Jersey thrown in, you can talk from the capital city of Sao Paulo to the city of Santos, the port of Sao Paulo, 50 miles distant; and you can also talk to Ribeirão Preto, a city of 25,000 in the northern part of the State. This city is conspicuous as the birthplace of Santos Dumont, the Brazilian national hero in the aviation world. It is also the greatest center of the coffee growing industry, and was recently placed on the motor map of Brazil by the Ford agent in Sao Paulo establishing a branch in it. Other cities in the State of Sao Paulo are served by long-distance telephones, as well as by a very complete telegraph system.

Lack of Good Roads

In the question of good roads you are equally surprised when considering parts of Brazil. The country is hopelessly without roads, but like in U. S. A. the feeling is strong that the automobile will build roads. Brazil is further back than Argentina in road building and much further back than the little country of Uruguay, which is the aggressive center in road building in South America.

It is impossible to drive a motor car from Rio de Janeiro to the summer capital of Petropolis, a distance of little over 50 miles. The City of Rio is surrounded by mountains, and to build roads over these would be very expensive. Good railroads have been built, and as usual roads have suffered where railroads have gone through. This is specially true where the government owns the railroad, as is the case with some lines in Brazil. It is almost impossible to conceive of a city of nearly 1,000,000, people and one of the finest located cities in the world, and a city literally filled to overflowing with expensive European automobiles, and yet not having a road on which you can drive to the summer capital where the government spends the summer months among the mountains, where the diplomatic heads live and where many of the great business men reside. You must take the trip by train. It cannot be made by automobile.

Being hemmed in by mountains naturally restricts the sale of cars in Rio, and it also has had a very restricting influence on the sale of motor trucks. Although you cannot drive out of the city to other cities there are many fine drives around the city, and in the mountains; in fact, there is one drive of nearly 60 miles through the adjacent mountains which is perhaps the finest scenic motor drive in the Western Hemisphere. The roads are excellent. We would be proud to have them in the White Mountains of New Hampshire or among the Rockies in Colorado. They are graded with the finest engineering precision. The surface is smooth and you are led near to the summits of high mountains, 2500 ft., with curves and straightaways that challenge the art of any road builder in Colorado or New Hampshire. These roads are of recent creation and stand a monument to the road-building influence of the automobile. They are being extended every year and it will not be long before you can drive from the Brazilian capital to other great cities in the country just as we can go to-day from New York to Chicago or St. Louis or Kansas City. It will not be to-morrow, or next year, or 5 years, but it is coming. We cannot tell how fast. The influence of the car will have a big bearing on the time required.

Sao Paulo Roads Best

All parts of Brazil are not so poorly served by roads as the vicinity of the federal capital. In this respect the City of Sao Paulo occupies a much superior position. The entire State of Sao Paulo is still backward in roads compared with practically any State in U. S. A. It is only in the last few months that the new road has been completed between Sao Paulo and its port of Santos. Early this year motor trucks were driven over the new road for the first time. Even at present that part of the road at the Santos end is very bad in wet weather, whereas the remainder is best described as a modern stone road. It is now possible to go by car in a few hours from one city to the other.

The road is rather unusual in that you have to climb 2700 ft. in going from Santos to Sao Paulo. Santos is at ocean level and Sao Paulo on a high plateau. You do not ascend this plateau gradually as you reach the mile-high point at Denver, Colorado, but the ascent is exceedingly abrupt. It is so abrupt that the railroad has resorted to a cable system to draw the cars up in groups of three, lowering three at the same time. The railroad has in making this 2700-ft. ascent divided the rise into five short divisions and adopted the cable system for each division. The entire rise is made in 7 miles. The railroad is one of the great railway engineering jobs of the world, and as it raises through the fog or clouds that hang on the face of the plateau its roadbed is a succession of tunnels through the rock alternating with steel viaducts over narrow gorges.

Rolling Coffee Lands

With the exception of this precipitous rise the entire State of Sao Paulo is a rolling country with soil in the best coffee sections as red as you ever saw soil in New Jersey or Georgia. This red soil is ideal for coffee culture; in fact, is considered the best in the world. The coffee grows on the hill tops. It revels in elevation. The valleys are used for other crops.

While the entire State of Sao Paulo is given over to coffee cultivation, do not gain the impression that in traveling across the State the eye falls on nothing but coffee bushes. This is literally true in many sections such as Ribeirao Preto, but after running through such a region you may go for 10 or 15 miles through a section not cultivated and you will not spy a single coffee bush. Coffee is the be-all and end-all of agriculture in the State, but rice, sugar cane and other products are cultivated. Coffee is the great crop, just as corn in Illinois or wheat in Kansas. The government of the State has for 40 years kept a keen eye on the coffee situation and much legislation has been passed to protect the coffee industry. Several years ago when everybody in Sao Paulo was planting coffee trees the government saw the dangers of over-

production, a situation which finally overtook the State and caused a disastrous coffee panic, and legislated, prohibiting the planting of more coffee trees, and went further, empowering the government to buy large quantities of coffee in order to keep it out of the market and so hold prices so as to return necessary profits to the coffee planters. This act on the part of the citizens of the State of Sao Paulo is but one example of their business acumen.

Coffee Owners Are Wealthy

From an automobile manufacturing viewpoint the State of Sao Paulo and the coffee industry are of premier importance. It is here that it is easiest to sell motor cars, motor trucks and farm tractors; and while Rio, the federal and business capital, is practically dead as a market, the State of Sao Paulo is the best market for U. S. A. automobiles in Brazil.

The owners of coffee plantations are wealthy enough not only to own cars, but motor trucks and farm tractors. Coffee culture is generally carried on in large areas. It is not a small-farm system as we know in Iowa, Kansas or any other State in the Mississippi valley. The industry is the one in South America that is not in the hands of foreigners in the sense that the nitrate industry of Chile, and the mining industry of Bolivia and Peru are so largely controlled by European or American industries. Railroads in South America are almost invariably controlled by foreign capital; so are telephone systems, telegraph systems, water works for cities, and many other public utilities. But coffee in Sao Paulo is an exception.

It is largely controlled by a group known as Paulistas, a hardy, adventurous white race that sprang from predecessors who traveled much through all the heart of South America in search of minerals. They bear a slight comparison with the Forty-Niners who worked their way across our prairies to the gold lands of the West. These Paulistas are an intensely business race, free from African blood, and are imbued with high ideals of government, agriculture and general business. The coffee industry could not be in better hands.

By government measures favorable to immigration they were able to induce enough whites from Europe to cultivate the coffee plantations, so that negro labor is scarcely known. On the other hand, the coffee plantation is one of the most cosmopolitan places to be found south of the equator. As many as sixteen different European and Asiatic nations have been represented in the laborers on a single plantation in the coffee-growing section.

Coffee in Brazilian Hands

While practically all of the coffee interests are controlled by Sao Paulo citizens, there are some of the largest plantations controlled by German and English interests, but their numbers are few. The industry is not in their hands.

The coffee industry is estimated in sacks of coffee. The average crop is 15,000,000 sacks. A sack weighs 132 lb. Upward of 1,000,000 tons of coffee are produced in the State of Sao Paulo each year. The State has well over 700,000,000 coffee bushes. There are over 16,000 large plantations, all of which are in the market for cars, trucks and tractors. Much educational work will have to be done. A few of them own cars and trucks, but the great majority have yet to be convinced that cars and trucks as well as tractors will all be investments rather than expenses.

Our U. S. A. cars are already selling in the City of Sao Paulo and also in the coffee country. The Ford dealer in Sao Paulo has sold over 800 cars, nearly all of which have gone into the coffee area. He has 110 sub-dealers in the State. Of these ten are regular dealers with salesrooms and who carry stocks of parts and accessories. The other 100 are generally salesmen who may keep their demonstrating car in a garage, or they may be the agent for National cash registers, Remington typewriters, Fairbanks-Morse scales or Singer sewing machines.

Many of our other makes of cars are represented in Sao Paulo, the city being the natural center for the State, just as Boston distributes to all of New England. Hupmobile has had strong connections for several years, and the dealer claims to have sold over 200 cars. The Hup first sold entirely in the coffee lands, but of late it has been introduced into the City of Sao Paulo and is now selling to the best families in the city. It is another example of how U. S. A. cars started selling first in the country and then started city invasion.

Overland has had representation for several years, but sales have not been so large as warranted, due to local agency difficulties. Cadillac has been represented, but has not been aggressively pushed.

Studebaker got established nearly a year ago. Arrangements were being made in June for Chevrolet representation. A dealer interested in Maxwell had ordered sample cars through a New York exporting house, but received coupés, runabouts and other closed models instead of five-passenger touring cars. There was little possibility of selling the closed types. The dealer was much displeased, but placed the blame entirely on the New York house. Dodge has just arranged for representation, as have one or two other makes.

The Jeffery Quad truck was demonstrated in the coffee lands for several weeks early last spring by George Gaidzik, export representative. He placed an agency for the cars and trucks.

Tires Are Well Handled

Practically all of our large tire concerns are represented, but not so well as in Buenos Aires or Rio. Firestone has representation in one of the largest garages in the city; U. S. has its agency with a supply house, and Fisk closed contracts in June with the Overland dealer, who also handles a line of accessories. Goodrich, Goodyear and a few other U. S. A. lines are handled by the Ford agent for Ford sizes. Michelin and Perelli are strongly entrenched. Michelin carries a large stock in Santos, so that a dealer can get all sizes and in any quantities within two days. Michelin pays the import duty on them.

As in all parts of Brazil there is plenty of gasoline through the entire State of Sao Paulo. You can buy gasoline in small villages as far as 14 miles from railroad lines. The gasoline is handled in 5-gal. cans, the same as in Argentina, and the price runs as high as 50 to 70 cents a gallon in our money. This holds back the sale of motor trucks quite seriously and is also a consideration in the purchase of a small U. S. A. car.

To-day there is not much pleasure driving in a motor car through the coffee lands due to the lack of roads. There are plenty of private roads through the plantations, but unfortunately you have to open gates when entering and leaving a plantation. Often these gates are padlocked and you must walk to the home of the plantation owner and receive permission to go through his private roads. You cannot drive from the city of Sao Paulo to Ribeirao Preto, the heart of the coffee country, without opening upward of 100 gates. Last June the automobile dealers in the city of Sao Paulo had a motor "raid" or test from their city to Ribeirao Preto. You go any way you may select, but have to be checked at all of the important towns and cities passed through on the trip. The rules permitted you to make the trip any time during the month of June and you could try as often as you liked. The distance is 350 miles. A Ford averaged 20 miles per hour for the distance and, as with the other cars, had to open the gates. Its time was 17 hr. and 20 min. A Mercedes made it in 15 hr. and 3 min.; a Zust in 15 hr. 13 min.; and a Gregoire in 17 hr. and 20 min. The Hupmobile and Benz made the best performances, making the trip in approximately 12 hr.

What Happens to a Neglected Storage Battery

An Autopsy on Cells Which Have Met an Untimely End—Symptoms of Trouble and How To Meet Them

By J. Edward Schipper

Fig. 1 — Judicious use of the hydrometer will ward off many minor battery evils

BATTERY TROUBLES AND REPAIRS

Symptom	Cause	Repair
Liquid low in one cell.	Cracked or broken jar.	New jar.
Electrolyte gravity won't rise—A.	Crystallized sulphated.	Recharge at slow rate of 3 amps.
Electrolyte gravity won't rise—B.	Lack of acid.	Go to service station if possible—if sure battery is otherwise O.K. add acid in outside container to bring up gravity, replace when cool.
Overheating.	Liquid low or charged too rapidly.	Refill with water and inspect regularly or alter generator regulation.
Electrolyte leaking at top.	Solution too high.	Draw out quantity with syringe.
Battery box disintegrated.	Acid eaten.	Do not fill so full.
Battery capacity low.	Undercharging.	Increase the generator output—have battery charged on outside current.
Buckled plates.	Overheating.	Charge at lower rate—keep liquid in cell—keep temperature below 110 deg.
Battery exhausts quickly while idle.	Short circuits.	Go over wiring and renew insulation.
Frozen battery.	Discharged in cold weather.	Damage may be irreparable—may try reforming charge for crystallization.
Rotting insulation.	Impure water — too much acid.	Use distilled water only or melted artificial ice.
Battery won't take charge.	Connectors loose—see crystallized plates.	Resolder connectors and plate holders.
Terminals corroded.	Acid leak through vents.	Clean with ammonia or washing soda.
Jars break rapidly.	Battery not fastened down.	See that proper cleats and bolts are fitted.
Separators punctured.	Overheating.	Renew separator and keep battery filled.
Lights rise and fall.	Battery low.	Recharge outside or by long run at 20 m.p.h.
Battery won't operate after storage.	Not maintained during storage.	Should have been kept charged — probably cannot be repaired owing to disintegration.
Lamps dim although electrolyte at high level.	Specific gravity too low.	Bring specific gravity up to 1.275 by charging—see that generator gives 20 per cent more current than lamp consumption.
Electrolyte down to 1.100.	Overdischarge.	Give reforming charge at 3 amps. until up to maximum density.
One cell dead.	Insulation destroyed.	Watch overheating and overcharging—keep electrolyte up.
Battery dead from usage.	Using without restoring.	Charge for 24 hr. at rate marked on battery or until electrolyte reaches 1.275.
Large sediment deposit.	Active material dropping.	Take battery to service station at once, as material has become loosened.

ALL three important forms of energy, mechanical, electrical and chemical, are used in the modern automobile. The mechanical has been with us so long that even the schoolboy is quite familiar with its principles. The electrical has been used in other lines to such an extent that it is not altogether a mystery. The chemical form, which is used in only one place, the storage battery, seems to be buried deep in uncertainty. Like most unknown quantities it is avoided and it is this condition that makes the average owner a contributor to an annual sum of $50,000,000 a year which may be called the Neglected Battery Fund.

The worst feature of this enormous loss and wastage is that it is due not so much to willful neglect as to lack of knowledge of what ought to be done and lack of information on what happens if the neglect occurs. Every man who owns an automobile knows that if he does not put air in his tires they will disintegrate much more rapidly than if the pressure were kept up to normal. Still a certain percentage will neglect the air in the tires, anyway. This same percentage will neglect the care of the battery even after they know what this carelessness is doing. The majority, however, realizing the results of not maintaining a proper state of affairs, take pains to see that conditions are such as to keep the cost level as low as possible.

Mechanical Neglect Rare

Neglect of the mechanical features of the car rarely occurs. Everyone knows that if oil is not put into the motor the cylinders will score and the life of the engine will not be anywhere near as long as it would be if it were kept properly lubricated. Wear is compensated for by adjustment. When a part is slightly out of order it is repaired at once before the damage goes further and affects parts which would otherwise remain in good condition.

All these principles apply to the chemical side of the car, in other words, the battery, as well as they do to the cylinder parts, or the tires. Neglect will cause certain well defined conditions to exist just the same as it will cause rim cutting in tires, scoring in cylinders and other definite conditions in the mechanical side of the car.

The point is that the owner will put oil in the motor because he knows exactly what will happen if he does not. He will put air in the tires because the condition which will result from not having the proper pressure is as clear to him as the fact that he will go hungry if he does not secure food. The automobilist of to-day is taking care of his car as he takes care of his own physical well being. He knows that good food will preserve his health. He knows that good oil will preserve his motor, but he does not know, taking motorists as a body, just exactly what will happen to his storage battery, the chemical element of the car, if he neglects it.

Storage battery books can be secured in any quantity and so can standardized directions on exactly how to take care of the battery; what the average owner does not know, however, is what is happening when this neglect occurs and it is purposed to show some of the actual conditions which have been found in batteries brought into service stations for repair long before the normal time for the end of the battery's life had arrived.

Primarily, the action of a battery is simple. It is simply a device which breathes in acid and discharges electricity or, conversely, breathes in electricity and discharges acid. The acid is the liquid which surrounds the lungs or plates of the battery. When the battery is charged the lungs are full of electricity and the acid surrounds them. When the battery is discharged the electricity is expelled from the lungs over the wires while the acid enters them. This is the fundamental process which takes place.

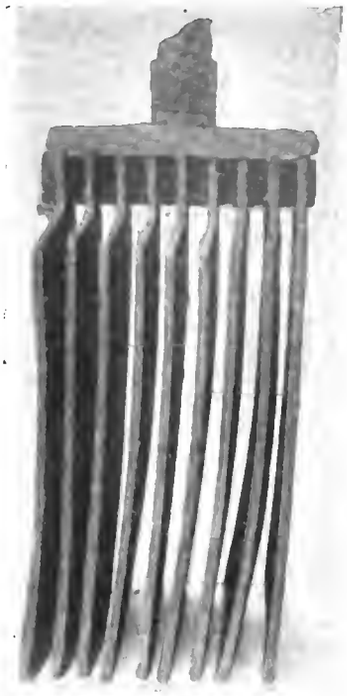

Fig. 2—An example of corroded terminal and warped plates

Any departure from normal conditions in the battery shortens its life just as any departure from normal conditions in life affects the health and period of existence of a man. A man must do a normal amount of work, take a normal amount of food and have a normal amount of sleep to remain in the best physical condition. A battery likewise must take a certain amount of food and must do a certain amount of work and have a certain amount of rest to attain its full period of life. The electrical system on the car is designed to maintain a proper balance between the feeding and exercise of the battery. If it is not doing so, this departure from normal is cutting into the life of the battery and making its owner one of the contributors to the annual $50,000,000 Neglected Battery Fund.

The first lesson that every battery owner receives is to keep water in it and to be sure that the liquid is covering the plates to the extent of at least ½ in. The Willard company alone has spent $250,000 a year in educating the public to do this and other necessary work. The campaign has had its effect so that now batteries which perish through the lack of added water have dropped from 90 per cent down to around 30 per cent. But even 30 per cent is so large that it is still found necessary by this concern to keep pounding away with its campaign. The percentage of people who know what they are avoiding by keeping the water in the battery is very small and it is interesting to point out what occurs from this neglect.

Only Covered Plates Active

Remembering that it is necessary for the plate or lung of the battery to breathe in acid before it can discharge electricity it will be seen that only those parts of the plates which are covered with the acid solution can bear any share of the burden of producing current. All of the plate above the level of the liquid is dead and useless. It is not receiving any food and it is not doing any work. If the arm of a man was shut off from the blood supply and was never used it would wither up and die. The unfed and unworked portion of the battery plate does the same thing. The material in it dries up. This is true both of the negative and positive plates in a battery. The negative plate, which contains a pure gray sponge lead, will crystallize above the point where it was submerged in liquid. This crystallized condition is commonly known as sulphation. The positive plate with its brown lead peroxide also suffers from the same cause and in much the same way when it is kept uncovered.

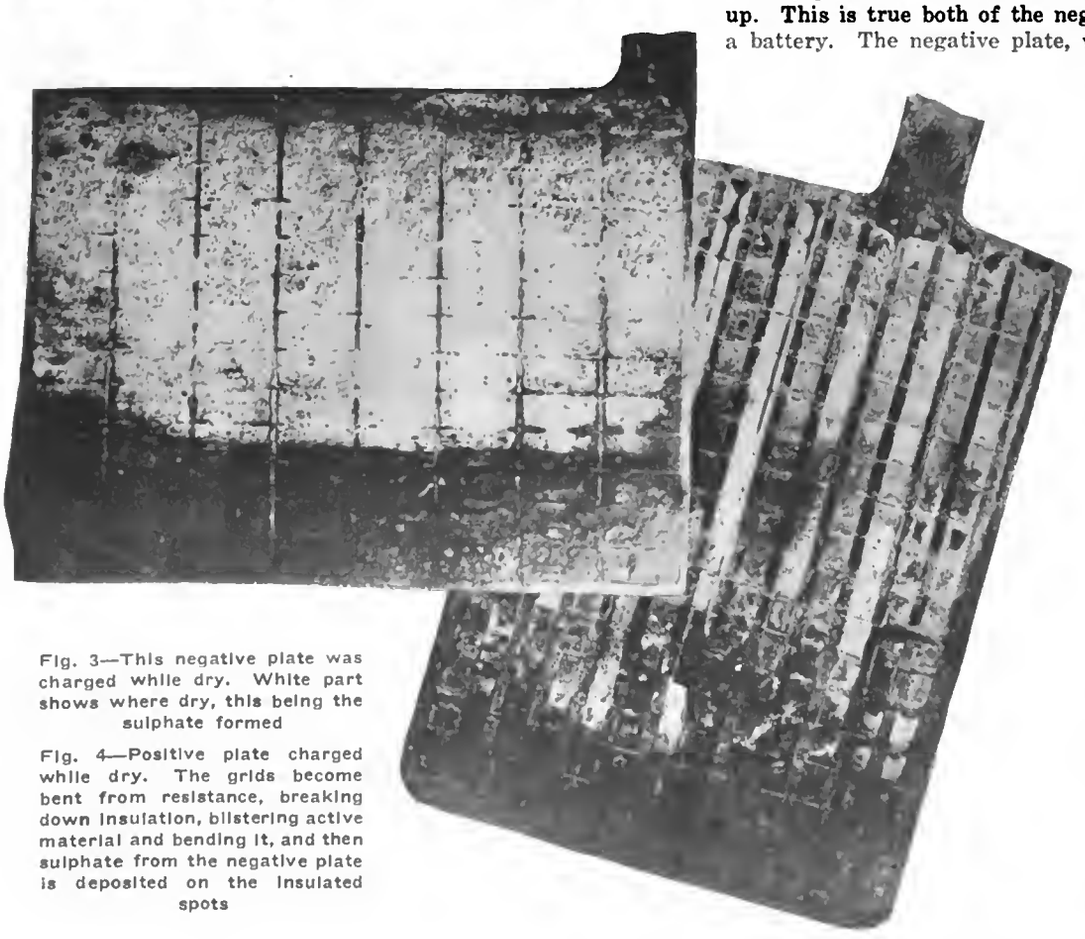

Fig. 3—This negative plate was charged while dry. White part shows where dry, this being the sulphate formed

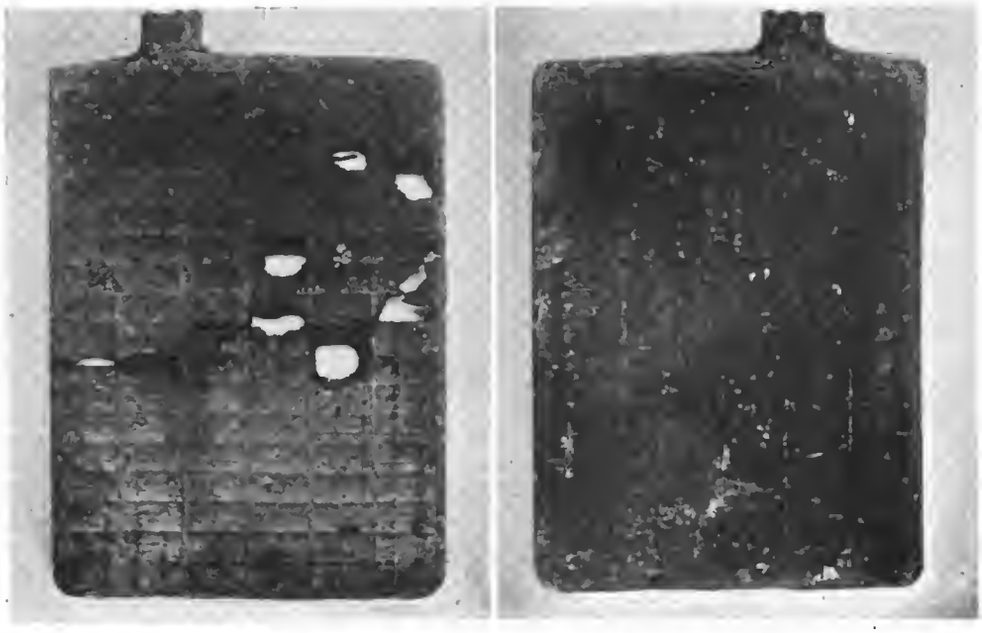
Fig. 4—Positive plate charged while dry. The grids become bent from resistance, breaking down insulation, blistering active material and bending it, and then sulphate from the negative plate is deposited on the insulated spots

It is quite clear that a battery which has only half the area of the plate covered by the acid solution or electrolyte can only possibly have half the capacity. Yet the electrical system on the car is designed for a battery of the entire capacity, and is pumping an electrical current into the cells of the battery at a fixed rate. This condition when the battery is not filled with electrolyte or flushed, as it is called, results in what battery men know as charging while dry. Owing to the rapid rate at which the small avail-



Left—Fig. 5—Positive plate crystallized. The material is burned through due to charging at a very high rate
Right—Fig. 6—Positive plate in good condition, which has been formed or charged

able plate area receives the current, what electrolyte is left rapidly boils away. The dry part of the plate, which is carrying the current, becomes warm due to the resistance of the grids. In the case of the negative plate sulphate soon forms, turning the active material into the hard, white crystalline structure which is shown clearly in Fig. 3, while with the positive plate the active material is first blistered due to the heat and this soon causes the plate to warp or buckle, breaking down the insulation or wood separator between the negative and positive plate thereby short-circuiting the two and rendering them useless. The battery, in other words, gradually becomes burned up through charging while dry.

If the owner could visualize what is occurring in his battery simply because he has neglected to put in distilled water once a week in Summer and once every two weeks in Winter, he would soon mend his ways. The negative plate shown in Fig. 3 and the positive plate in Fig. 4 are taken directly from a battery which has suffered from this neglect. It is quite useless for the owner to attempt to tell the man at the battery service station that his cells have been receiving attention because the tell-tale line showing the height at which the electrolyte stood is seared indelibly on the plates.

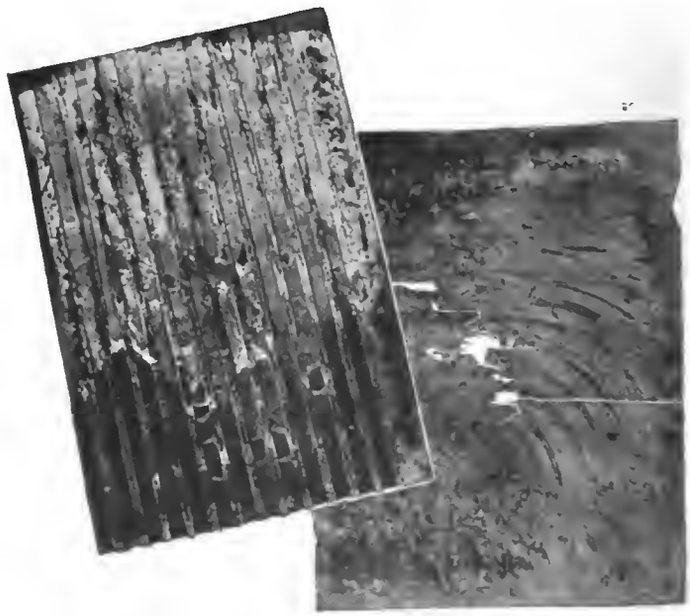
Owner Adds Water Only

Owing to the fact that the battery is of a rather complex chemical nature and that it is thoroughly sealed to prevent damage and leakage, the addition of water is the only actual administration that the owner can, as a general rule, give his battery. But if this is carried out it will generally prevent a great many troubles which can result indirectly, as well as directly, from a temporary period of neglect. It is necessary to use pure water such as distilled or melted artificial ice, in order that the pores of the active material in the plates are not clogged with impurities.

The effect of temporary neglect is partial crystallization or sulphation, as it is generally known, which the generator is not always capable of bringing back and which may require the use of what is known as a reforming charge or a slow charge over a long period which will have the effect of restoring the active material toward its original condition, although it is very seldom that it can be brought altogether back.

When sulphuric acid is poured into water the action is accompanied by heat. A rise in temperature of the solution will take place. A simple experiment will demonstrate this to you very clearly. Never pour the water into the acid but the acid into the water. If the water is poured into the acid the heat is generated so rapidly that it may result in an explosion which might cause serious damage.

When the battery is receiving its charge, the acid is leaving the plates and entering the water. This naturally causes a rise in temperature of the electrolyte. The resistance of the grids and other parts of the storage battery also causes a rise in temperature and the electrolyte of a battery receiving a charge will be seen to be gasing or bubbling. This rise in temperature must be very carefully watched or it will do damage to the battery. A battery should never be allowed to go above 110 deg. in temperature. If it gets up to 120 deg. it may de-



Left—Fig. 7—Separator, showing acid line. This separator has not broken down but shows charging while dry. The grooved side faces toward the positive plate
Right—Fig. 8—A separator broken down by the heat. It has been practically burned away

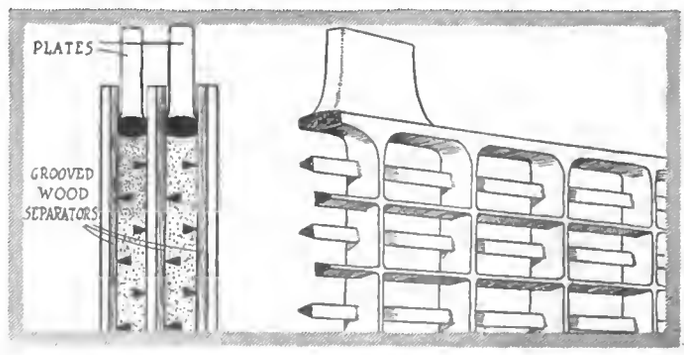


Fig. 9—Showing staggered grid and method of separation

teriorate rapidly. The more rapid the charge the more rapid is the feeding of acid into the water, and hence the quicker the temperature rise. It is therefore very important to know that the battery is not being charged too rapidly lest it cause trouble.

Fever from High Charge Rate

When a man's pulse becomes too rapid it is generally accompanied by a feverish condition. Even a slight rise in his temperature indicates to a physician that a process of destruction is going on in his body. The heart is pumping blood too rapidly and the influx of heat is affecting the body cells. In the same way the electrical anatomy of the car may be out of adjustment and electrical energy may be flowing too rapidly towards the storage battery. In other words, charging is occurring at too rapid a rate. It is being overfed and the result is that the temperature rise is too great and beyond the physical strength of the lead grids with the active material which is pasted into them. This causes the plates to warp and bend against the insulation. If it continues for any length of time this insulation is broken down and a short-circuit between adjacent plates puts an end to the activities of this part of the battery.

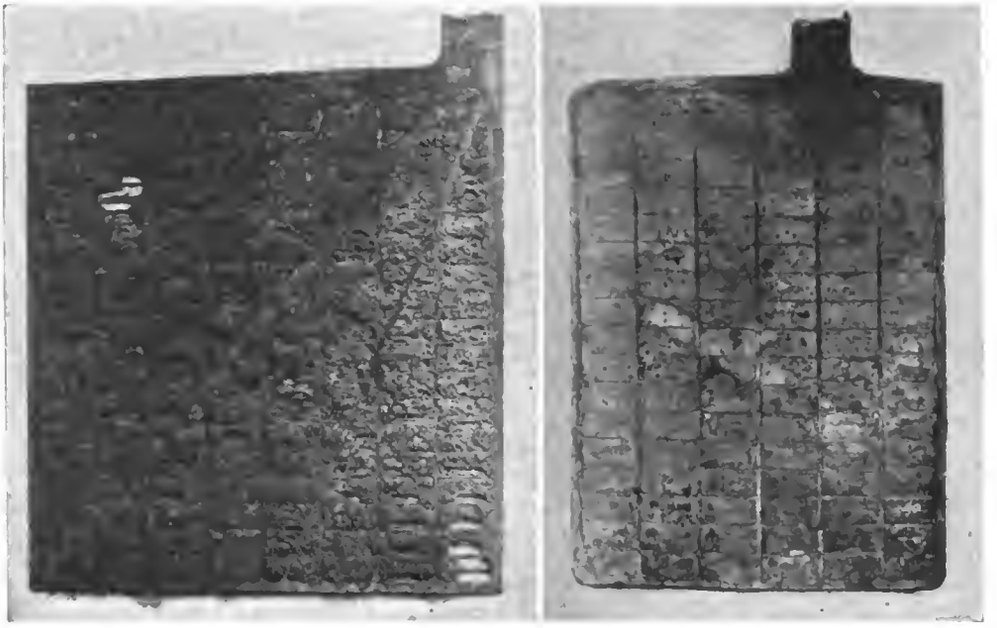

Fig. 10—Left—Negative plate sulphated right through from overheating caused by charging at too high a rate
Fig. 11—Right—Charged negative plate in good condition

This high temperature which occurs from charging at too high a rate also has its effect on the active material. It gradually becomes burned through and hard. Look at Fig. 5 which shows a positive plate that is crystallized, the material in it having been burned through due to this high rate of charging. Compare it with Fig. 6 which shows a positive plate in its normal condition. The color of a normal positive plate is a reddish chocolate brown. Deviations from this color show that some circumstances which should not have existed, have had their effect on the active material. A negative plate which has been sulphated clear through or crystallized completely from over-heating is shown in Fig. 10. This is also due to charging at too high a rate. The negative plate in good condition is a slate gray or lead color, as shown in Fig. 11.

Fig. 12—Left—Frozen positive plate. The material is loosened and falls out, due to standing idle while discharged
Fig. 13—Right—In a positive plate under the same circumstances the material becomes hard. Gray sulphate at top left corner is caused by broken-down insulation

Shorts from Broken Separators

Every time one of the wooden separators or insulators is broken down it puts the negative and positive plates on either side of it out of business. These plates must be insulated from one another in order that the current produced by their relationship may flow through the electrolyte, over the exterior line and back again to the battery. When they are in contact, due to the breaking down of an insulator, they are short-circuited upon each other and subtract their value from the strength of the battery.

It is readily possible for the battery service men to judge from the condition of the separators how the battery has been treated. Fig. 7 shows one of these separators in which the acid line is apparent, showing that the battery has been charged while dry. The separator is not broken down in this instance but it would have become so if the conditions indicated had been maintained for any length of time. The grooved side of the separator is shown. This goes toward the positive plate, the other side is flat and is toward the negative.

Separators which have been completely broken down are illustrated in Fig. 8. These have been disintegrated through

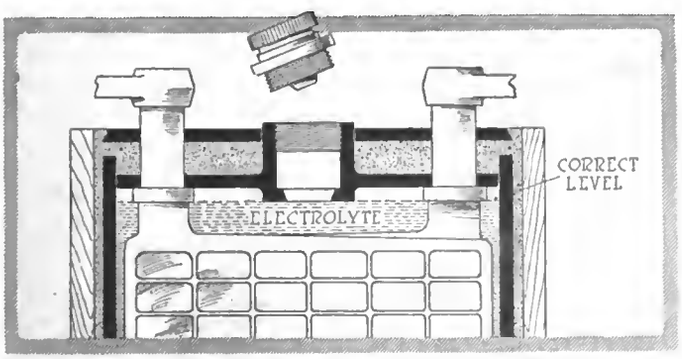

Fig. 14—Section of cell, showing correct level of electrolyte

heat and through contact with plates which have buckled due to the high temperature. It is quite frequent that the separator will break down just in one particular spot, allowing the two plates to come in contact with one another at this point. In disassembling the battery where this state of affairs has occurred, there will generally be a spot of the gray sulphate from the negative plate on the chocolate-brown surface of the positive.

The greatest clue that the owner has to the condition of his battery is in the use of the hydrometer syringe. As the thermometer is to the physician, the hydrometer syringe is to the battery doctor. A completely charged battery will give a reading of between 1.275 and 1.300, and if any cell is found to be below this reading, continually, the battery should at once be brought into the service station.

Starving the Battery

Starvation can bring down the vitality and health of a man just as well as overfeeding can do so, and in the same way a battery may be put into bad condition through not receiving enough current. Insufficient charging may be due to the fact that the generator is not delivering enough current, that the battery has been in a car which has not been used or in which frequent demonstrations of the starter have been made without recharging the battery or through some other conditions of abnormal service which causes the current to be taken from the battery without restoring it.

A man who has been starved for a considerable time could not be set down before a heavy meal. To do so would be disastrous and the same rule applies to a battery. A battery which has been overdischarged or undercharged for some time cannot be given a heavy charge to bring it back to its normal condition. It must be fed slowly just as the man must be given a little food at a time in order gradually to bring back his organs to their normal condition.

If a heavy charge is sent into a battery that has been starved for some time it will immediately overheat and then destroy the active material. If the battery is brought to a service station it is given a slow reforming charge so that the temperature of the electrolyte does not rise above 100 deg. Fahrenheit at any time. The charge is continued until the gravity of the electrolyte rises as high as it will. When it is found that the gravity has remained the same for 2 or 3 days with continued charging the battery is considered to be rejuvenated as far as possible. In some cases, this rejuvenation may take place in a few days; at other times it may take from 10 days to 3 weeks. It must be remembered, however, that just as starvation has left its mark on the constitution of a man, regardless of his recovery, it has in the same way had its effect on the life of the battery.

Battery's Wear through Usage

Batteries are very much like tires in a great many ways. If they are kept filled they will last a much longer time than if neglected in this respect. This applies to both tire and battery. The better the care given either the longer they will last, although each has a normal life. A battery's life is about 18 months. A leaky cell must be repaired as quickly as a leaky tube would be. It very often happens that the liquid in one cell will be found to drop down much more rapidly than in other cells. This should be an immediate indication that something is wrong. There is a leak through which the electrolyte is running away. The result is that the plates in this particular cell are being left dry and they will suffer in the way in which plates described and illustrated have suffered if the matter is not attended to at once. A cracked jar is generally due to traveling over a rough road with the battery not firmly clamped down. This corresponds very closely to a cut in the tire due to traveling over sharp stones on the road. If the leaky cell is not repaired at once it throws an additional load on the good cells and not only causes the deterioration of the dry plates left uncovered by the escaping liquid

Fig. 15—Cell cut away, showing how the plates are fitted into place in the jar

Fig. 16—Negative plate at the left and positive at the right, showing appearance before charging has taken place

but causes the good cells to overheat due to too rapid charging.

If a tire is filled with too much air it is over-stressed and it is harmed just as much almost as with under-inflation. The same way with a battery. It should not be filled too full, because overfilling will cause the solution to get down into the battery box and the acid will quickly rot whatever metal or susceptible material with which it comes into contact. There is a little vent passage in the cell cover through which the water is put into the battery. The water should be well below this as when the battery is in use gas bubbles are forming which quickly causes the pressure in the battery to rise if relief is not offered by an uncovered vent. When this vent is not open the water and acid are naturally forced out and run down inside the box.

A mistake which is very often made is in the addition of acid to the battery in order to bring the specific gravity reading on the hydrometer up to normal. No acid should be added by the owner, except when far away from a service

Fig. 17—A cracked battery jar, due to vibration caused by insecure fastening

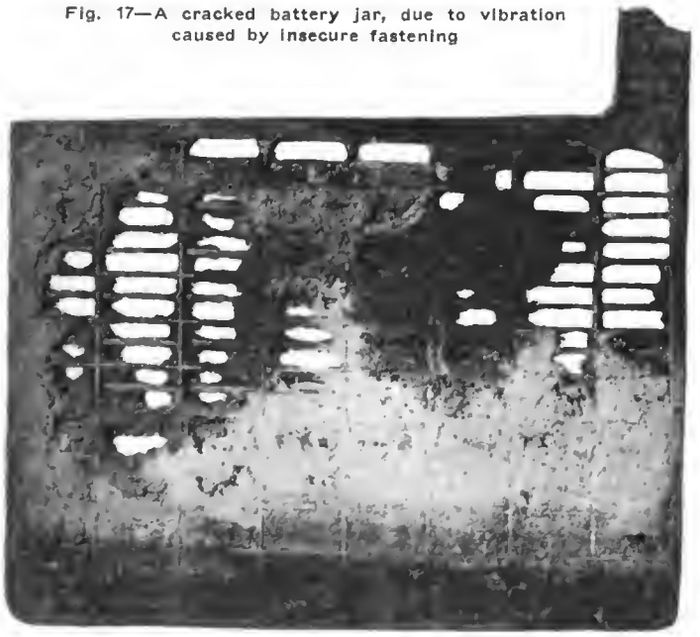

Fig. 18—Negative plate badly overheated, due to charging too rapidly. The acid line is clearly shown

station, as it takes a battery expert to know when the time has arrived for the acid to be put into the solution. If acid is added before it is necessary the solution becomes too strong and it immediately attacks the plates and separators, destroying the insulation and killing the entire battery. The effect is that when the battery is charged when the strong solution has been added the electrolyte becomes stronger and stronger until it is easily capable of breaking down the insulation.

At this time of the year many car owners are thinking of storing their batteries for the Winter. Improper methods of storing have destroyed many hundreds of batteries. There are two dangers in Winter: first, that the battery will remain idle in a discharged state, allowing the active material to become hard, or second, the battery may freeze. Normally a battery will discharge itself to a great extent if left standing idle two months. When discharged the electrolyte has a specific gravity of 1.12 and the battery will freeze at 20 deg. above zero. When the battery is fully charged and the electrolyte is up around 1.28 it will not freeze until 98 deg. below zero. Thus the danger of freezing is quite great on a discharged battery, but remote on a charged one.

What happens when a plate has been standing idle for some time is shown very clearly in Fig. 13 which is a positive plate that has remained in a discharged state until the material has become hard and stony. This can be corrected to a large extent by a very slow, long-enduring reforming charge. At the top left of this plate is shown a spot of gray sulphate which has resulted from the overheating acquired by an attempt to charge this hardened plate. The insulation has been broken down and the negative sulphate has come in contact with the positive plate. This plate is buckled but this cannot be seen in the illustration.

Results of Freezing

The results of a frozen battery can be seen in Fig. 12. The effect has been very much like water in stone or in a radiator. Owing to the discharged condition the acid has nearly all entered the plates leaving only water with very weak proportion of acid surrounding them. The result is that the water freezes at quite a high temperature, and as it freezes the little particles of ice expand and loosen the material, and even crack the grids containing it. As soon as a charge is given the battery the grids expand and the loosened material drops to the bottom, leaving the grids exposed as shown in the illustration. The whole battery has become disintegrated simply due to the fact that it was attacked by cold while in a discharged condition.

The battery should be fully charged when it is put away for the Winter and every 2 or 3 weeks should be given an additional charge to bring it up to its proper gravity reading. If the car is put away for the Winter and this is neglected a battery that readily starts the engine in the Fall may be nothing but a container and a mass of muddy, disintegrated material in the Spring.

An important point to remember in connection with batteries in which the material has been allowed to crystallize to a certain extent, due to the fact that it has been too long in a partially discharged condition, is that the specific gravity of the electrolyte cannot always be brought up to the proper gravity with the generator. In other words, the active material has gotten out of the control of the electric system on the car and must be reformed or given a fresh start. With a battery of this kind the charging should be given at about a 2 or 3 amp. rate and should not be allowed to rise beyond 5 or 6 amp. As explained in a case of this kind the temperature should not go over 100 deg. This tends to break up the crystals and to put the material back in the proper condition.

The more rapidly a battery is charged the hotter the solution becomes, and therefore when it is removed from the car and charged on an external circuit where there is plenty of time it is much better to charge at 3 or 4 amp. than it is to charge at a higher rate where the temperature of the solution goes above 100 deg. It must be remembered at all times that the solution becomes dangerous and a factor in the destruction of the plates if it goes above 110 deg. As soon as a battery is crystallized or sulphated to any extent the slow rate or reforming charge becomes imperative or else the plates will heat where the crystallization has occurred and remain cool in the normal places, thus giving unequal expansion to the plates, causing them to buckle and to drop the active material. A buckling plate exerts enough force to crack the container of hard rubber.

One precaution which is often neglected is to be continually on the alert for short circuits. These will drain the battery quickly, allowing it soon to come into its discharged state. In this condition sulphation or crystallization occurs, and the battery will deteriorate much more rapidly than if it were under a state of normal discharge.

Brake Design Not Up To Par

Engineers Could Improve Present Types with Comparatively Little Effort—Brakes Now Neglected Detail—Inefficient, Troublesome and Noisy Compared with Other Parts

By A. Ludlow Clayden

THAT the conventional automobile chassis is still many years from anything like finality of design admits of no argument. Studying the development of the past 10 years it seems that as soon as some feature becomes accepted as really nearly perfect a discovery is made which upsets that conception. At present there are a few remaining portions which have been improved but little since the beginning of things automobile, and one of the most important among them is the means for arresting motion, in other words, the brakes.

The average automobile brake suffers the following defects:

It is insufficiently powerful.
It requires too much effort to apply it.
It needs too constant adjustment.
Its surfaces need too frequent renewal.
It is harsh in action.
It is affected by oil and dirt.
It is a prolific creator or rattles and squeaks.

The most remarkable thing about the whole subject is that any good engineer could design better brakes if he would only take the trouble, but it is quite usual to find that a man who will spend months calculating the stresses in almost every other part of his car will accept any sort of brakes without a thought. This is not confined to any one country; it is true of every place where motor cars are made, though least true of Italy, because the Italian factories being all at the foot of the Alps the need for exceptional brakes is forced upon the designers. Still, even the brakes of Italian cars are not always ideal, as the requisite power is often obtained at the expense of harshness.

Magnitude of Forces

Before discussing any details of design it is well to consider the exact amount of work which the brakes have to do, and the starting point is, of course, the amount of energy that the brakes have to convert into heat while stopping the car. As a basis for calculation Table I gives the kinetic energy of cars of various weights, traveling at speeds from 20 to 60 m.p.h. From this table it is, of course, possible to obtain the amount of energy to be got rid of in reducing speed from one velocity to another by simple subtraction of the value of stored energy at the lower from that belonging to the higher rate of travel.

Just to get some idea of the magnitude of the forces, let us take a typical example. Assume a car moving at 60 m.p.h. and weighing 4000 lb. to be stopped in 15 sec. Then in 15 sec. we have to dissipate 484,000 ft. lb. of energy.

In 15 sec. the car will have traveled 660 ft. and to absorb 448,000 ft. lb. in 15 sec. will need a retarding force of $\frac{484,000}{660}$ or 733 lb. This force, of course, being applied in a direction opposite to the direction of motion.

Now the effect of applying a brake to the road wheel drums is to produce friction and create heat, and we need, in this example, to have a quantity of heat produced which will be equal to a force of 733 lb. acting through a distance of 660 ft. It is required to find the necessary pressure on the brake drum to create this amount of friction.

There is one fundamental thing which is often overlooked, but which is the basis of all brake design. This is that the size of the braking surface, its area that is, has nothing to do with the power of the brake. The retarding force applied by a brake is always the product of the pressure applied by the driver, multiplied by the leverage of the connecting links and again multiplied by the coefficient of friction between the two materials of which the brake surfaces are composed. This acts as a tangential pull on the brake drum, so making the drum wider does not add to the force.

The amount of energy absorbed by the brake for each revolution is the product of the retarding force and the circumference of the drum, so by increasing the diameter we can increase the amount of energy absorbed per revolution. By increasing the width we can lower the unit pressure per square inch on the brake and so increase its life, but we cannot increase its power.

Suppose, for the sake of simplicity that the brake drum is 3 ft. in circumference, and that the tire on the rear wheel is 34 in. A 34-in. wheel will turn seventy-four times in covering 660 ft., and a brake drum of 3 ft. circumference will cover a peripheral distance of 222 ft. while the 34-in. wheel is traveling 660 ft. This means that the retarding force applied at the brake drum must be three times the retarding force required to act on the whole car, or 2199 lb. Now the average coefficient of the friction materials commonly used for brake lining is between 0.5 and 0.3. It is safer to take the lower value so as to allow for possible greasiness. Doing this we see that the pressure which must be applied to the drum, *via* the brake band or shoe, is no less than 7257 lb. or nearly ten times the amount of the retarding force required to be applied to the car as a whole.

Of course, frictional resistance is independent of the areas in contact; it depends only upon the pressure between the surfaces; so we may spread this total pressure over as many

Table I—Kinetic Energy of Moving Vehicles

WEIGHT OF CAR	SPEED IN MILES PER HOUR					
	10	20	30	40	50	60
1,000	4,200	13,400	30,200	54,000	84,200	121,000
1,250	4,040	16,750	37,750	67,500	105,250	151,250
1,500	5,880	20,100	45,300	81,000	126,300	181,500
1,750	6,720	23,450	52,850	94,500	147,350	211,750
2,000	7,560	26,800	60,400	108,000	168,400	242,000
2,250	8,400	30,150	67,950	121,500	189,450	272,250
2,500	9,240	33,500	75,500	135,000	210,500	302,500
2,750	10,080	36,850	83,050	148,500	231,550	332,750
3,000	10,092	40,200	90,600	162,000	252,600	363,000
3,250	11,760	43,550	98,150	175,500	273,650	393,250
3,500	12,600	46,900	105,700	189,000	294,700	423,500
3,750	13,440	50,250	113,250	202,500	315,750	453,750
4,000	14,280	53,600	120,800	216,000	336,800	484,000
4,250	15,120	56,950	128,350	229,500	357,850	514,250
4,500	15,960	60,300	135,900	243,000	378,900	544,500
4,750	16,800	63,650	143,450	256,500	399,850	574,750
5,000	17,640	67,000	151,000	270,000	421,000	605,000

square inches as we like. The larger the surface the less wear will take place and the longer will be the life of the brake. Suppose we decide that 100 lb. per square inch is a good pressure to employ. Then the two brake drums ought to have an area in contact with the bands or shoes of 72 sq. in. Three ft. is 36 in., so two brakes 1 in. wide will give us enough surface. Probably, however, 100 lb. per sq. in. is a good deal too high, 50 lb. or even less is better, so let us calculate on a basis of 40 lb. per sq. in., and we see that the drum area necessary is 181 sq. in. Now, the whole drum is not effectively surrounded by braking surface. It is not safe, with the conventional sort of brake, to assume that more than half the circumference of the drum is operative, so we arrive at the stage where half the surface of two drums, or the whole surface of one drum, must contain 181 sq. in. If the circumference is 36 in., as before, this means that the width of each drum must be 5 in.

Maximum Braking Force

There is another way of approaching the problem, which is to calculate the maximum force which can be applied by the driver to the brake band through the linkage. In the case of a band brake the pressure normal to the drum is equal to the tension divided by the radium. Assume the brake pedal has an 8 to 1 leverage and the link which actually contracts the band a 4 to 1, giving a total leverage of 32 to 1. Then assume that the maximum comfortable pedal pressure is 100 lb., which is about right, and we see that the maximum tension applied to the band will be 3200 lb. and so the maximum normal pressure on the drum will be 20,096 lb. and the maximum frictional resistance 6029 lb. Acting on a drum of 36 in. circumference, this friction will absorb 18,087 ft. lb. per revolution, which means that to stop our 4000-lb. car at 60 m.p.h. would need 27 revolutions of the wheel, equal to a distance of 240 ft.

Suppose this is not considered good enough, we have only two alternatives, one to increase the pressure by increasing the leverage, and the other to increase the *diameter* of the drum, so that the circumference and the distance, "length of rub," so to speak, per revolution shall be increased.

Increasing the Leverage

Obviously it is not easy to increase the leverage, the limit of distance through which the pedal can be moved conveniently, and the need for proper clearance when the brake is off limits the leverage very definitely. Suppose, therefore, we want to stop in 100 ft. with the hypothetical car, we must make the drum $\frac{240}{100}$ times the diameter or 27 in. This again is not practical, or hardly so, but the example serves to bring out the exact effect of increasing diameter and shows that we ought to use the very largest diameter brakes that can be accommodated.

Let us now make a closer study of the possible leverage obtainable commercially. Assume a 16-in. diameter brake drum. Then we shall require a clearance when the brake is off of not less than 1/32 in. between drum and band. This means that the inner circumference of the band when free of the drum is 50.395 in as against 50.265 for the drum, a difference of 0.13 in. or just over ⅛ in. There will be some spring in the band and the lining is compressible to a small extent, so we cannot safely assume that the brake will be fully applied by a contraction of less than ¼ in. The little lever mounted on the brake band itself will give a 5 to 1 leverage, so the ¼ in. on the band will mean 1¼ in. movement of the actuating lever. Coming now to the pedal, for comfortable application of the brake this should not move more than 4 in., giving an additional leverage of 3.2 to 1 and a total leverage of 16 to 1. With the hand lever we can easily get three times this leverage or 48 to 1; so assuming a 100-lb. push on the pedal or a 50-lb. pull on the lever we can reckon a band tension of 1600 lb. for the foot brake and 2400 lb. for the hand brake, giving a drum pressure of 10,000 lb. in the first case and 15,000 in the second, approximately.

Avoiding Lost Motion

This rather laborious and lengthy excursion into elementary arithmetic has for its excuse a desire to show up strongly how vitally important it is to keep the clearances as small as possible and to avoid lost motion in the linkage. There are some metal transmission brakes which can be applied fully by a 2-in. pedal movement with a 20 to 1 leverage which means that only 0.1 in. of movement on the brake shoes or bands is necessary to make the difference between complete freedom and full application.

However, there is still another thing to be considered. The limiting power of a brake is the maximum tractive effort which can be exerted by the tire on the road. Of course, the coefficient of friction of a rubber tire on a road varies enormously according to the road surface; it is impossible to do more than take a very rough estimate of what its average is. However, it is fairly safe to base calculation on the assumption that the coefficient is not far removed from 0.5 on a dry, hard road. This means that the maximum tractive resistance which can be applied as a tangential force at the periphery of the road wheel is half the weight supported by that wheel. In the case of a 4000-lb. car the maximum resistance force would thus be 500 lb. if the weight is distributed equally. But this is 500 lb. *per wheel*, which at once shows us how front wheel brakes score. With all brakes on the two rear wheels, the maximum retarding force we can apply will be twice that for one wheel; with brakes on all four wheels it will be four times this amount.

Coming back to the brake itself, we now see that there are two limitations. At one end of the chain there is the adhesion of the tire on the road, and at the other is the effort which can comfortably be exerted by the hand or foot of the driver. The driver's effort, acting on a pair of rear wheel brakes, can be regarded as divided equally between the pair, so the driver's effort multiplied by the leverage, again multiplied by 2π and multiplied by the coefficient of friction for the brake lining, gives us the retarding force applied tangentially to the brake drum. This amount multiplied by the radius of the brake drum must be equal to the maximum tractive force the pair of road wheels can transmit, multiplied by the radius of the road wheel.

Putting this in the shape of a formula:

Let P, be driver's effort,

L, the mechanical advantage of the brake linkage,

u, the coefficient of friction of the brake surfaces.

Then

$2\pi P\,Lu = R$, the force resisting motion acting tangentially to the brake drum circle.

Let r, be the radius of the brake drum,

r_1, be the radius of the road wheel,

W, the weight on one wheel,

0.5 the coefficient of friction of rubber on a road.

Then for the two rear wheels,

$$R\,r = W\,r_1$$

Taking 100 lb. for the value of P and 0.3 as the value for the brake friction coefficient we get:

$$188\;L\,r = W\,r_1$$

Or,

$$L = \frac{W}{188} \times \frac{r_1}{r}$$

We have seen in a previous computation that it is reasonably easy to obtain a 16 to one leverage for the brake pedal. Therefore, assuming this to be the value of L we can vary the formula above as follows:

$$r = \frac{W\,r_1}{3008}$$

which enables us to obtain the proper diameter of the brake drum when the weight of the car and the size of the tire are known. Calculating out a set of values from this formula shows something very interesting, which appears in the following table:

W = weight on one wheel	$\frac{W}{3008}$
500	.166
600	.195
700	.233
800	.267
900	.299
1000	.332

This means that a car weighing 2000 lb. with 500 lb. on each wheel needs brake drums just a trifle over a sixth the tire diameter, and that a 4000-lb. car with 1000 lb. on each wheel needs drums less than half the road wheel diameter. What the table really shows is that the leverage must be increased as the weight of the car increases or that the driver must be called upon to exert a greater effort. There is no alternative, unless we gear up the brake drum so that it revolves faster than the road wheel. The effect of doing this is immense. If we gear up the brake drum four to one relative to the road wheels we can satisfy the conditions with a drum one-quarter the diameter needed on the road wheel itself. With a four to one rear axle ratio a 4-in. transmission brake is the equivalent of a 16-in. brake on the wheel so far as retarding force for a given pedal pressure and leverage is concerned. This accounts for the great power obtained from the usual sort of transmission brake with a very small pedal pressure.

It is not easy to make brake drums for a passenger car much larger than 16 in. and it is seldom possible to have the drums wider than 2½ in., 3 in. would be the absolute maximum on most cars. Thus, if the transmission brake is undesirable, and we are not content to have a heavy acting brake, the leverage must be made greater. There is only one way to enable this to be done and that is to cut the clearances very fine indeed and to put such accurate workmanship into all the details of the brake links that there will be practically no lost motion in the linkage.

The study of the forces needed to arrest the motion of a car suggests that it is really rather remarkable that so little progress has been made with power applied brakes. It surely would not be very difficult to devise ways for using the power of the engine to operate the brakes, either by purely mechanical means or via a compressed air tank or the electric storage battery. We have abandoned the manual labor of cranking an engine by making the power plant store up energy which can be drawn upon to do this work for us. Surely it is only reasonable to ask for a mechanical brake that could be controlled by a lever requiring no more effort to move than the spark advance. It is easy to obtain air, oil or electrical pressure from auxiliaries on a gasoline engine; why not make use of one or the other and so improve not only the convenience but the safety of the automobile?

Eliminating the Garage Repair Pit

ELIMINATION of the garage pit has been accomplished by the Harold L. Arnold establishment of Los Angeles, Cal. Arnold is distributer for Hudson and Dodge Bros. cars, and Vim trucks, and one of his aims is modern and efficient equipment for his shop.

Poorly lighted, greasy, damp pits did not appeal to Arnold's ideas of service, or to those of his mechanical superintendent, Paul Hinkley. Thus when Hinkley suggested raising the car from the floor on racks, instead of putting the men in holes beneath the floor, he was told to devise some practical means of doing so.

A trial pair of service racks were built up from channel iron, split to form legs, and securely bolted together to withstand excessive weight. These were designed to raise the running board of the car 6 ft. from the floor, and thus to permit free access to all underparts. From the time the room to work between the cars. By aid of the cranes two system was seen to be a success. Immediately a complete equipment was made up for the station.

The racks are arranged in rows along the sides of the repair shop, on lines so arranged as to allow the men ample room to work between the cars. By aid of the cranes, two men may hoist a car to the racks in a few moments, or in case of necessity one man may raise it alone.

Service racks used by Harold L. Arnold, Los Angeles dealer, to eliminate garage pits

The workman is thus enabled to work in a well lighted and ventilated room, with perfect freedom of motion. For the short man platforms are provided, and ladders are handy for the mechanic to climb into the cars when necessary. The whole tone of the work has been improved; better work is done in a shorter time than with the pits, and the health and comfort of the workman has been forwarded.

Riker Trucks Beat Mules

UNITED STATES ARMY Truck Train No. 13, composed of thirty-one 3-ton Riker trucks, recently covered the 800 miles from Columbus, N. M., to San Antonio, Tex., in 13 days' actual running time. The standard day's travel for a four-mule team is 17 miles; thus 47 days would have been required to make the trip with the old style army transport, according to the United States Army regulations.

Tractor Transmission Serious Problem

Average Power Lost in Drive 50 Per Cent—Big Gear Reduction Necessary Makes High Efficiency Difficult To Obtain

By A. Ludlow Clayden

¶ This is the fourth of a series of articles based on an intimate study of tractor requirements and the efforts of the tractor engineers to meet the problems in design and construction arising from the demands made upon the machines in active service. The author has been in close touch with the tractors and the manufacturers at the recent demonstrations, so that this series of articles accurately reflects the conditions discussed, besides giving a clearly defined idea of the principal trends in tractor engineering.

IN three previous articles the writer has given his impressions of the problems of tractor engineering as related to engines and arrangement of wheels or other driving methods such as caterpillar treads. In this, the last of the series, the problem considered is probably one of the most difficult of all, namely, that of reducing the engine speed to the final drive speed efficiently.

Supposing a road speed of 2½ m.p.h. and a piston speed of 1000 r.p.m., the ratio of piston speed to road speed is as 100 to 22, which does not look very great. When we translate both linear speeds into revolutions, however, the ratio looks very different. For example, assume a 6-in. stroke, giving 1000 r.p.m. for the engine, and also assume a 6-ft. driving wheel, which revolves at 11.7 r.p.m. at 2½ m.p.h. and the ratio becomes 10,000 to 117 or 87 to 1.

Now such a reduction as this is difficult to get efficiently in any sort of machinery; it is difficult in factory drives, where gearing can operate under ideal conditions, and it is still more difficult, therefore, under the poor circumstances of tractor operation. As to the means employed, nearly all tractor makers are now using an internal gear and pinion, or an external gear ring, on the driving wheels, this providing the major part of the reduction, in conjunction with a smaller step down in the gear train between the engine and the shafts of the final drive pinions. Often there is a spur gear reduction followed by a bevel gear reduction and then the final drive; three separate steps in all.

We can assume 90 per cent efficiency for a properly made and lubricated spur gear, and 85 per cent for the bevel gear, giving an efficiency of 76.5 per cent for the two reductions. The efficiency of the final drive is problematic. If it is a gear ring and pinion, either internal or external, the efficiency might be over 75 per cent with complete inclosure and proper lubrication. This would mean a total efficiency in transmission of 57.4 per cent, or a loss of 42.6 per cent. If the gear is unprotected and only haphazardly lubricated, as is almost always the case, the efficiency of the final drive may be much less than 75 per cent.

It is noticeable that the practice with regard to the final drive at present is to use teeth on the ring gear like those of a chain sprocket, and a pinion consisting of a cage with a number of small rollers mounted in place of teeth. This is not so efficient under the best conditions as properly cut teeth with true rolling contact, such as can be obtained with the small, accurate gears used in truck transmissions, but the distance between the center of the big wheel of a tractor and the pinion center obviously cannot be accurate within limits far too wide to permit of proper gear alignment, wherefore the roller pinion is possibly a good compromise.

Still, even if proper alignment is not possible, proper protection and lubrication could be obtained at fairly small cost, as we have not the complication of the brake drum introduced on truck layouts. A sheet metal case tight enough to hold grease is quite practical, as at least one tractor manufacturer has shown. Even then, however, a drive that cannot be accurate is not real engineering; it is satisfactory for places where we have plenty of spare energy,

An Aultman-Taylor tractor employing an external gear method of drive

engineers who believe that nearly all the required reduction could be taken care of by a single worm gear, that 50 to 1 at least could be so handled. They point out that very great reductions are used on cranes, hoists and elevators with high efficiency. Others consider that better results would be obtained by using a slight reduction in a bevel drive on the axle, and then all the rest in an inclosed, lubricated gearbox. Still others think that gearing should be applied direct to the engine, so that a 2 or 3 to 1 reduction is obtained between flywheel and clutch.

However, having cited the disadvantages of driving the wheels by gear rings, it is right to look at the drawbacks of the other suggestions. A worm gear or a bevel gear applied to the axle means the use of a live axle instead of the simple, dead I-beam forging that can be employed with the ring gear drive. Such an axle has to be enormously strong, as the torque applied to the driveshafts by an 80 to 1 reduction from the engine can well be imagined. Not only must the driveshafts be very strong, but the hub and spoke construction of the wheel has to withstand a great deal more stress than it does with a drive applied nearer to the rim.

Summing up, the appearance is that a live axle drive would cost much more than the present prevailing custom, and the suggestion also follows that it would weigh a great deal more also. If we add to the excess weight we shall be throwing away again a proportion of the power saved by greater transmission efficiency, so there might be little or nothing gained for the extra first cost. But these contentions assume that the only way to use worm or other inclosed accurate gearing is to have a live axle of motor truck type, only bigger.

Is this necessarily true? Remembering that in tractor development we are going far outside the limits of motor truck and automobile engineering generally, may there not be other ways of applying gearing to road wheels?

As an example of the sort of possibility that exists a very peculiar design of truck put out in 1913 by the Austin company of England may be mentioned. This had a dead rear axle, and there was a very peculiar gearset admidships. Inside the gearbox was a change-speed transmission of the usual sort, a bevel drive and a differential. On the differential driveshafts were two bevel gears of peculiar angle, and these drove two propeller shafts which in turn operated individual bevel drives on the two back wheels. Of course the propeller shafts ran angularly from the gearbox to the wheels. This design is complicated to the last degree, it is impossible to believe that it could be efficient with all those bevel gears in the train, but it might be simplified. For very large tractors the use of two engines geared together is not an impossibility. It is easy to see how a spur gear reduction might be arranged to provide two propeller shafts that would drive the rear wheels through individual worm gears, for instance. Such ideas are not necessarily practical, not necessarily good even in theory, they are given merely to point out how much there is untried that might be tried; to emphasize how little we really know concerning the best way to set about getting 80 to 1 ratios.

Friction Drive Is Used

Leaving these realms of imagination and returning to the practice of the day, it is remarkable that many tractor makers favor friction drive for part of the transmission. It is seen applied to both light and heavy machines, and has been developed in several different forms. In the friction drive itself no very large gear reduction is obtainable; it is more often used more to provide a facile control than for obtaining the reduction, it takes the place of a clutch perhaps, or it provides a ready means for getting a reversal of direction.

In this connection the example of a particular machine may be mentioned. The Albaugh-Dover tractor has a unique friction drive which eliminates the differential, embodies the reverse, and gives all the gear reduction save that provided by the ring gears on the wheels. The following is not supposed to be an exact detail description, but it gives the principle. Fig. 1 is a diagram of the layout, and the friction drive pinions *A* and *B* are both mounted on a shaft which is practically an extension of the crankshaft. The driven wheels *C* and *D* can be so moved that they are brought into contact with either of the pinions.

Considering the wheel *D*, this can be put in driving contact with either *A* or *B*, and consequently *D* can be driven either forward or reverse: the same applies to the wheel *C* also, of

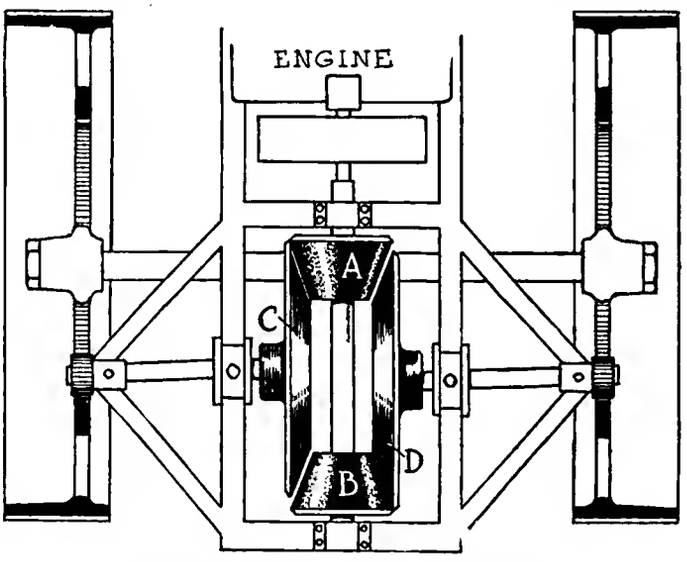

Fig. 1—Diagram of the friction drive used on the Albaugh-Dover tractor. This eliminates the differential, without sacrificing the reverse, and gives all the gear reduction except that effected by the ring gears on the wheels

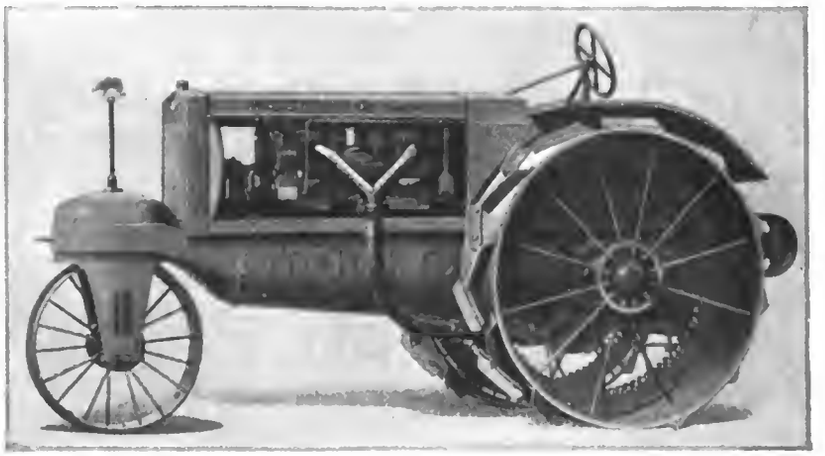
course. If *A* and *C* are in contact, and *B* and *D* the drive will be in one direction, while if the contact is reversed, so that *A* and *D* and *B* and *C* are the pairs the direction of drive will be reversed. Again, if both *C* and *D* are simultaneously engaged with *A* one will have forward motion and the other reverse, and engaging both *C* and *D* with *B* will reverse this action.

This means that by moving *C* and *D* the drive may be ahead or astern on both wheels, or ahead on either and astern on either in any combination. This allows the machine to turn in its own length. On the outer ends of the shafts *C* and *D* are the pinions of the ring gears that drive the road wheels, and there are no other gears.

A point which should be noticed especially is that the big wheels *C* and *D* are metal and the pinions *A* and *B* of compressed frictional material. This is very important, because the greatest difficulty with friction gearing is the liability to make a "flat" when starting. Where the metal part drives and the frictional material is driven it is easy to make a flat on the surface of the softer member of the pair, but when it is the softer that drives there is not much risk of flatting the hard metal of the driven member.

In operation it is noticed that the parts *C* and *D* get quite hot, but not nearly as hot as previous experience with friction drives would lead one to expect. Of course there is plenty of contact, and no differential slip such as is always taking place with the common form of friction drive that has a square-edged wheel in contact with a flat disk.

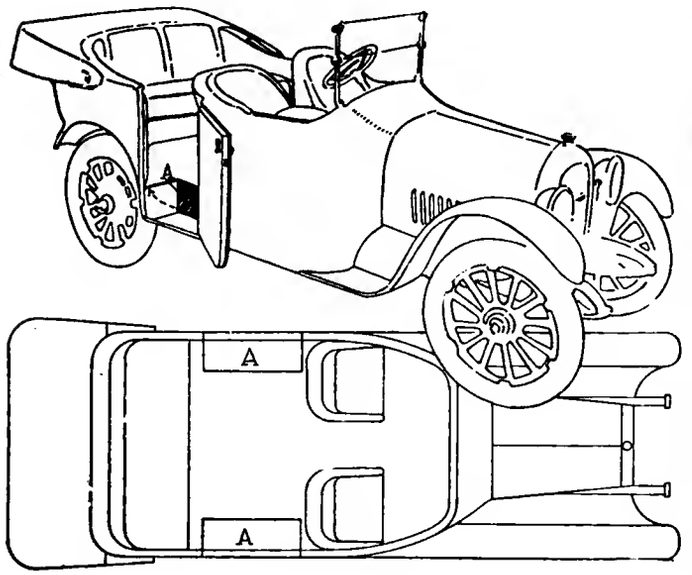
Several machines have a flywheel or its equivalent, edged with frictional material, and two metal disks placed one on each side so that one is used for forward motion and the other for reverse. In these cases the gear reduction on the friction drive is rarely as much as 2 to 1, and a spur gear train does the rest. Such applications simply replace the clutch by something a little more troublesome which absorbs a small amount of power, and the elimination of a reversing gear in the transmission seems hardly enough compensation. The main objection to friction gearing is twofold, it always absorbs perceptible power and it is subject to considerable wear both on the soft surface and on the metal one; further it is affected by moisture as a rule, in fact it is a form of transmission that takes a good deal of keeping in order one way and another. These difficulties may be overcome, they may be at a minimum in some of the existing tractor applications, but they have been prominent in all applications to passenger cars. The writer has driven a car with friction gear nearly 15,000 miles, so the statements as to its troubles are not theoretical, but are based on actual experience.



Wallis Cub tractor which has clutch and gears housed in a steel case forming the frame

Of course our old friend the hydraulic transmission is being mentioned, as are electrical transmissions, in discussing possibilities of the future, but it is not likely that anything requiring more understanding than a simple spur gear, or at most a worm drive, will soon find a place on a tractor. At the risk of painful reiteration it may again be said that the worst fault at present seen is lack of protection and lubrication. House the gears as well as the gears of a truck axle are housed; lubricate them as an automobile engine is lubricated, and the speed reduction will be obtainable without excessive loss of power. Nature has provided the horse with a skin impervious to weather and the steel mechanism of a tractor needs no less a protection, down to its uttermost detail of construction.

An Unusually Roomy Body Design



A BODY for which a patent has been applied has been recently designed by a Massachusetts man, in which the floor is enlarged to increase the carrying capacity. As shown in the illustration herewith there is a single entrance door for the driver and passengers, with divided front seats to allow him to reach his position. The side of the body is bent out and forms the fenders and in this way eliminates the running boards while the low step is secured by undercutting the floor in the manner shown. The body metal is bent out to serve as a mud guard on the rear wheels. The actual fenders here are eliminated as the wheels are within the body line.

Eliminating the Fenders

The idea of the designer, H. J. Childs, of Taunton, is that the fenders are unsightly and occupy space which could be included readily within the body. When the door is open for entrance the closure marked *A* drops, giving the undercut floor which allows of easy entrance. When the door is closed this part of the floor automatically goes up to the level of the remaining floor space, rendering the interior surface as flat as could be desired.

Automobile Inventors Active Abroad

Kerosene Carbureters Continue to Occupy Prominent Place Among New Ideas—A New Suggestion for Spring Inclosure—French Invention Includes New Valve Gear and Peculiar Gearset—Muffler Used to Generate Electricity—A Novel Drive System for Tractors

NEW ideas and inventions have been prominent in the British automobile journals in the past few weeks, covering a very wide range. *The Commercial Motor*, London, has been publishing a series of descriptions of kerosene carbureters, of which some have been reproduced in THE AUTOMOBILE. The most recent is the invention of Cyril Pullin, a well-known motorcycle racing driver, now of Beavor Lane, Hammersmith, London. The following is *The Commercial Motor's* account of the device:

"The passage of the fuel may be traced from the float chamber through the three-way cock (which is shown in section) along the inclined jet into the throttle barrel, which is designed so that the requisite volume of air is drawn past the jet at right angles to it, and causes thorough atomization of the liquid fuel. It passes thence through a tube, which is taper in form, being smaller at the bottom end than at the top. This choke tube—and, by the way, there are three of them, with a jet and passage in the throttle valve to each—is contained in an exhaust-heated vaporizer. Above the vaporizer is a pipe which serves to collect the gas issuing from these three tubes and to deliver it to the induction manifold, in which it is conveyed to the cylinders.

Separate Float Chamber for Kerosene

"The three-way cock connects the three jets to one or other of the two float chambers, one of which serves for gasoline, the other for kerosene. A reference to the sectional plan at the right-hand top corner of the drawing will enable the reader to understand how this is effected.

"The supply of kerosene to the three-way cock is regulated by means of a screw-down valve; this may be arranged so as to be operated from the dashboard. The supply to each jet is also capable of being regulated by a similar valve.

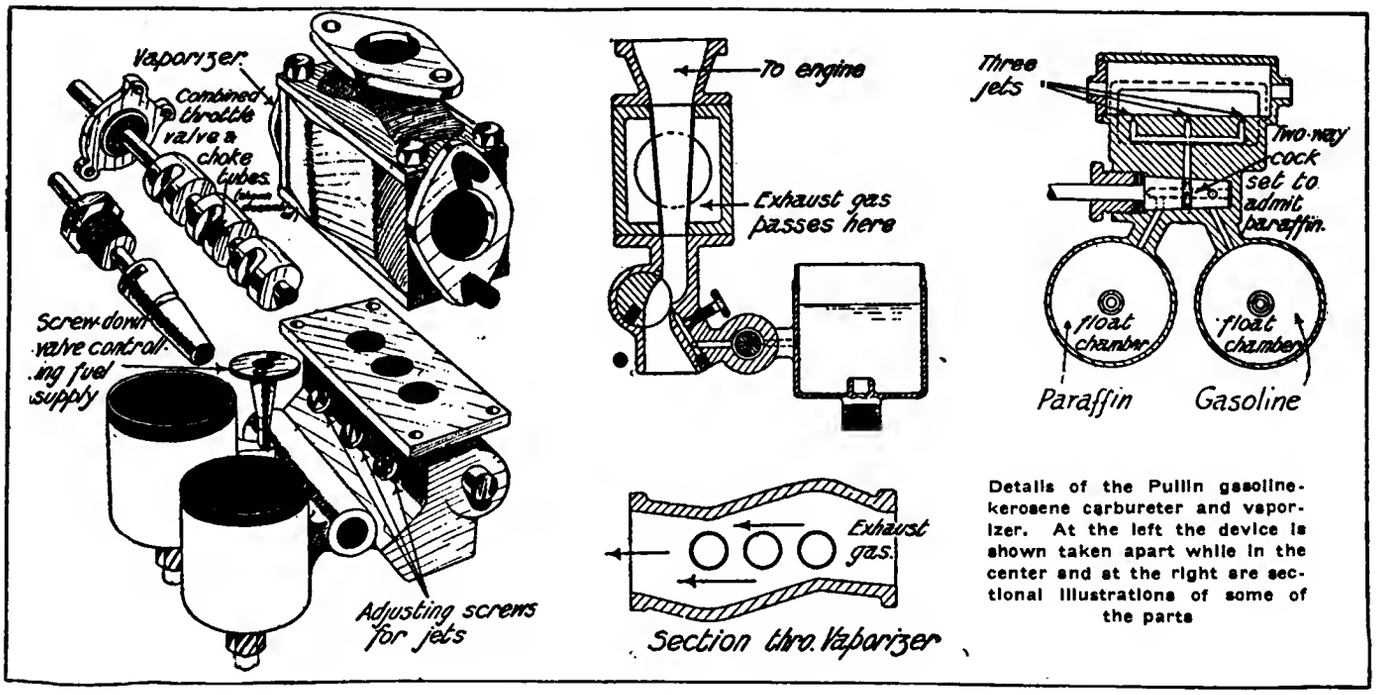
"In the central portion of our illustration, which shows the carbureter dismantled, is depicted the combined throttle valve and choke tubes. This throttle valve is cylindrical and is made in three parts, which are adjusted before the carbureter is sent out so that the jets, Nos. 1, 2 and 3, come into operation in turn; an additional slot in the throttle valve also allows of No. 1 being used as a pilot jet for idling or slow running.

"We have not space to deal at length with the theoretical considerations which led the inventor to this design of carbureter. It will be sufficient if we state that the tapering tubes are calculated as to their size with reference to any type of engine for which the carbureter may be intended, the object being to insure, so far as possible, that gas of practically atmospheric pressure and at a stated temperature enters the cylinders. By this means, packing of the cylinders with mixture at high temperature—and therefore liable to pre-ignition—is avoided.

"Attention is also directed to the peculiar shape of the vaporizer. This 'dog's hind leg' path along which the exhaust gases are forced to travel, causes them to impinge with greater frequency upon the vertical tubes containing the mixture."

Permanently Inclosed Springs

Quite a different sort of invention is quoted in *The Autocar*, Coventry, this being a cover of permanent metallic sort to inclose springs. The illustration is almost self-explanatory, so only a brief description is given:



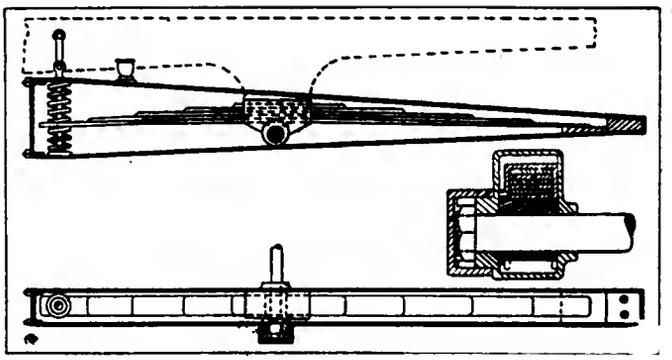
Details of the Pullin gasoline-kerosene carbureter and vaporizer. At the left the device is shown taken apart while in the center and at the right are sectional illustrations of some of the parts

"The accompanying drawings show a spring system designed by Lt. J. M. Sanders, Litchfield Lodge, Keynsham, Bristol, England. The object of the designer has been to provide a permanent protection and oil bath for the springs, and to attain this end he has inclosed a cantilever spring, as shown above, in a taper tubular torque and radius member on each side of the chassis. At the rear end each spring rests upon a special seating secured inside the end of the casing, and the casing itself is intended to be secured to the back axle while the spring moves within it.

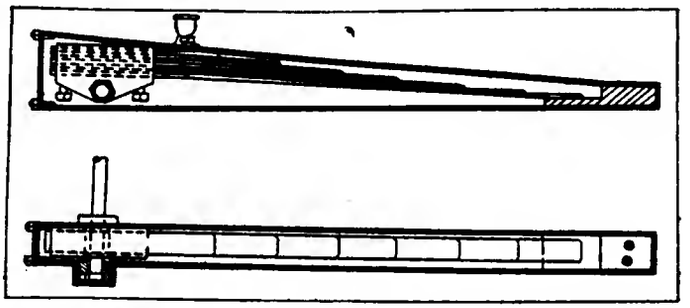
Two Helical Springs

"At the front end both the casing and the spring are supported by two helical springs, the longest leaf of the cantilever being supported between the two supplementary springs as shown, while the casing itself makes use of the same helical springs for its abutment above and below. Both cantilever spring and casing are pivoted on the same center, as shown in the cross-sectional view, so that there is no relative movement between them at this point, although this is not an essential feature.

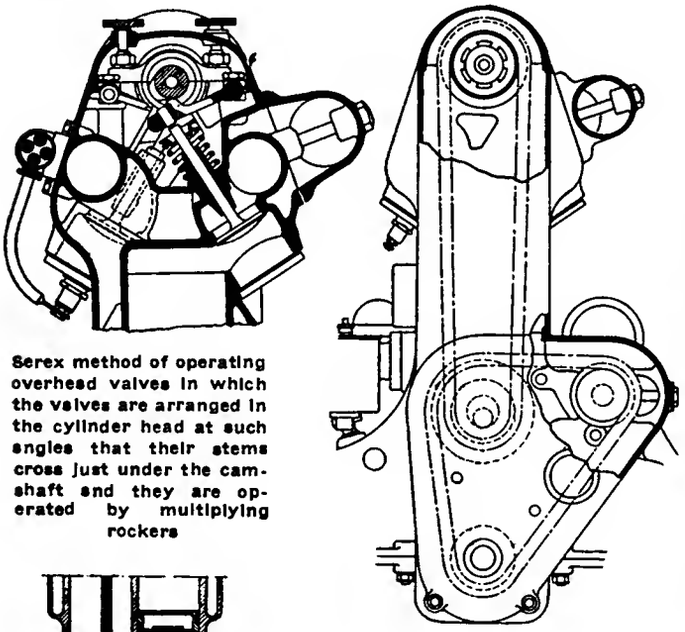
"In the case of a grasshopper spring the casing and the spring, as shown in the illustration below, are pivoted in a similar way to that adopted in the case of the cantilever spring on one and the same center, and the rear end of the spring rests upon the seating provided for it within the casing.



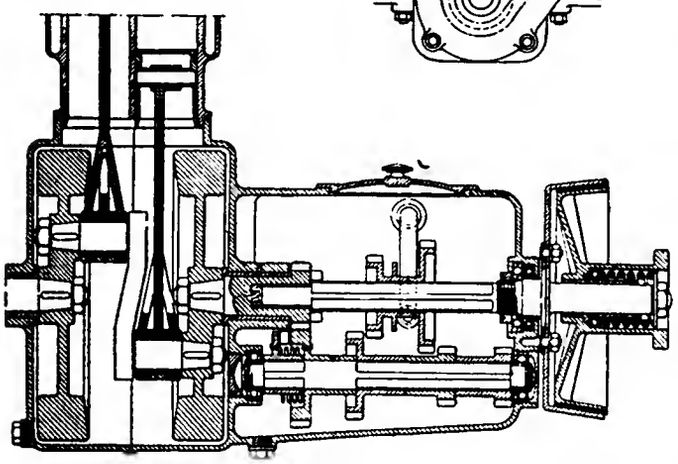
Sanders system providing a permanent protection and oil bath for springs as applied to a cantilever type, together with an enlarged view of the trunnion bearing



In the case of a grasshopper spring the Sanders system is applied as above, with the casing and the spring pivoted in a similar way to that employed with the cantilever, the rear end of the spring resting upon the seating provided for it within the casing



Serex method of operating overhead valves in which the valves are arranged in the cylinder head at such angles that their stems cross just under the camshaft and they are operated by multiplying rockers



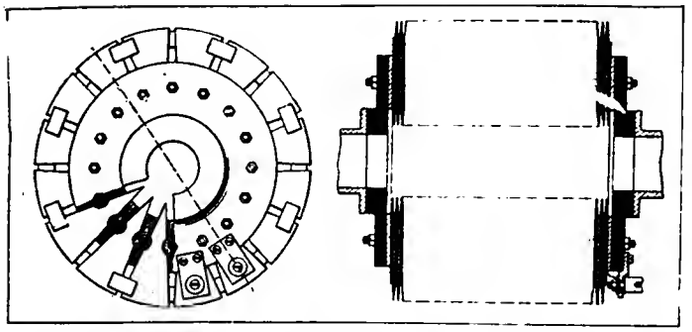
Morin gear set which has the first motion constant mesh pinion secured to the end of the camshaft so that the countershaft runs continuously. The clutch is at the rear of the gearset, the inner member being connected with the propeller shaft and the outer to the sliding gear shaft in the transmission

"In both arrangements the spring casing is closed at the front end and rendered oil-tight, and by means of the oil filler provided (shown in two of the views) the casing can be kept full of oil, so that the spring leaves themselves work constantly in an oil bath, and the pivot bearing of the spring and casing are kept thoroughly lubricated. In assembling the parts the spring is inserted through the open front of the casing, and the pivot bolt is then pushed through the side of the casing and the spring bearing. The cantilever type spring is mounted at the center on an eccentric pivot bearing in order that, when the body is fitted upon the chassis, the spring may be set to raise or lower the frame of the chassis so as to render the whole structure normally horizontal."

It is to be regretted that the inventor has apparently neglected to evolve a method for applying his inclosing system to springs of semi-elliptic type.

Ingenious French Valve Gear

The official journal of the British Patent Office is a record of practically all European inventive activity. One recent French invention is for a method of operating overhead valves by C. E. Serex, 81 Avenue Mozart, Paris. In this the intake and exhaust valves are arranged in the head at such angles that their stems cross just beneath the camshaft and they are operated by multiplying rockers. Presumably the object is to obtain compactness. Another part of the same patent consists of the method for driving the overhead camshaft. It is well known that there is always trouble when it is attempted to drive such a shaft by chain from the crankshaft, the length of the chain and its speed both being undesirable. To overcome these troubles Serex uses two chains. The first is a triangular layout with adjustment on the magneto or generator pinion, and this operates a large sprocket at half speed. From the half-speed sprocket a second chain is taken to the camshaft, it running at only half the linear speed of the chain in the triangular drive. To adjust the chains the half-time sprocket is first moved so as to take up the slack in



Combined muffler and electric current generator, current being obtained by heating one part of a thermo couple while cooling another part, the couple consisting of two different metals. By using a series considerable electrical pressure is obtainable

the upper chain, and the triangular chain is then tightened by moving the magneto pinion.

Inverts Transmission Layout

Another French idea is shown in a patent granted to G. H. Morin, Les Coteaux de Saint Cloud, France. This shows a gearset having the first motion constant mesh pinion secured to the end of the crankshaft so that the countershaft is running continuously. The clutch is at the rear end of the gearset, the inner member being connected to the propeller shaft and the outer to the sliding gear shaft in the transmission. The constant mesh gear on the countershaft is not mounted directly upon the countershaft, but is free to turn within the limits allowed by a coil spring, of which the fixed end is attached to an arm secured rigidly to the shaft. As shown, the gear changing would not be selective, but progressive. It will be noticed that the engine shown in connection with this transmission is apparently a four-cylinder V type, so it is probable that the patent has been secured while developing some entirely new sort of vehicle.

Muffler Generates Electricity

Electricity can be obtained by heating one part of a thermo couple while cooling another part, the couple consisting of two different metals. The potential obtainable from one couple is small, but a series can provide considerable electrical pressure. A series of such couples is usually known as a thermopile.

The idea of the inventor in this instance is to use some of the waste heat of the exhaust to generate electricity, and he therefore proposes to form a muffler from a series of thermo couples. The appliance as a whole consists of a pile column or chain of elements which according to one style of construction take the form of flat rings or annular vanes of metal or metallic alloys so arranged as to constitute a thermopile for generation of electric current, the rings of one metal or alloy alternating with rings of a different metal or alloy. These rings are arranged in couples and are joined near their outer and inner edges. Asbestos or other suitable insulating material is interposed between the rings except at their junctions. The exhaust gases and other heated products of combustion from the engine are directed to pass into and through the muffling chamber which the rings provide centrally in the appliance, and the rings are thereby heated at their inner junctions.

The outer junctions or contacts and adjacent parts are kept relatively cool by means of air circulation to assist in which the rings may have air holes, or cooling may be effected by water jacketing. Instead of being composed of rings as above described the silencer as constructed in accordance with a modification is composed of plates, vanes or discs, and these are so arranged as to provide and inclose the requisite space for expansion of the exhaust gases and other products of combustion.

Among the substances instanced by the inventor as suitable for composing the appliance are bismuth and antimony and alloys of these with zinc. Other substances may be employed, being of such nature as will insure generation of current of adequate power for effecting ignition lighting of lamps and charging of batteries.

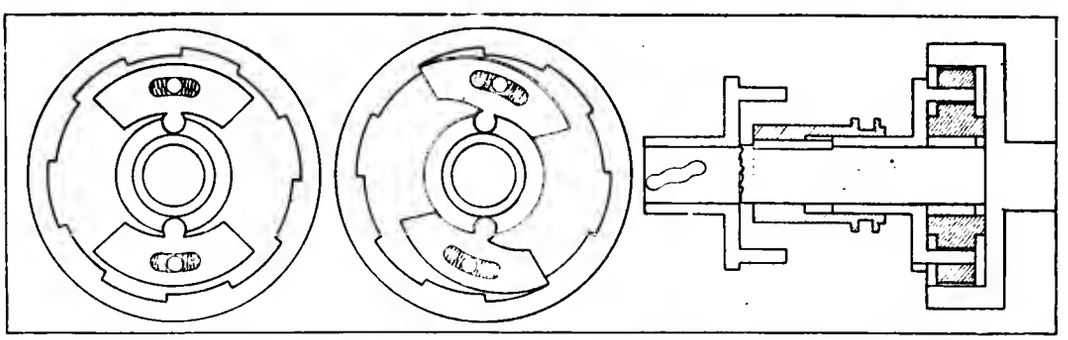
There would probably be some difficulty in regulating the current, as its voltage would depend upon the internal temperature, and this would change with the load on the engine and corresponding throttle opening.

Clutch Drives and Steers Tractor

The *Motor Trader*, England, describes a form of clutch which has been actually made and tried out in tractor service. How long the edges of the teeth on the clutch rings stand up is not stated. The description follows:

"The inventor and patentee of the free-wheel clutch layout shown in the accompanying two drawings is G. T. Taylor, proprietor of the West Kent Motor Works at Westerham, Kent, England. The district referred to provides about as good or drastic a test of the gripping and dirigible capacity of a field tractor as could be wished, and the invention in question is the outcome of Mr. Taylor's experience as a seller of such machinery, and discovery of the shortcomings in both respects of the normal petrol-paraffin tractor. Mr. Taylor has fitted his new mechanism to one such tractor, and we believe the results have been a great improvement of the tractor in question. Mainly, as will be seen, this device consists of a pair of pivotally mounted (clockwise and anti-clockwise) pawls free to engage against the ends of a series of slots in the periphery of a drum, provision being made for their engagement and disengagement at will by manual control. Following is the text of the description and claims furnished by the patentee:

"There are two gears fitted inside a bevel casing, or inclosed in oil-bath on back axle, each gear having a lever with three positions, giving forward, neutral and reverse positions, one controlling the right-hand wheel and the other the left, the drive being taken through a clutch to each wheel. In driving forward for, say, ploughing, both levers are used in the forward position, so that each clutch drives its respective wheel forward, but either wheel can over-run the other to allow for any deviation from the straight steering line. On turning to the right, the right lever is put in the neutral position, freeing the right wheel, then the left clutch only is driving, causing the tractor to turn sharp to the right, being driven by the



Left—Taylor's free-wheel clutch gear for tractors, consisting of a pair of pivotally mounted pawls free to engage against the ends of a series of slots in the periphery of a drum, provision being made for their engagement and disengagement by the operator. Right—The engaging mechanism of the Taylor clutch gear

outside wheel. For turning to the left, the left lever is put in neutral position and the right wheel takes the drive. For reversing one lever or both is put in the reverse position, accordingly as to whether it is desired to turn or go back straight. In driving on the road, where the brakes may be required, one lever is put in the forward position and one in the reverse, thus driving with one wheel and braking with the other. The ordinary gear levers on the tractor are worked in the usual manner.

Exporting Standard Tires

IN the *Motor Trader*, England, there has recently appeared the following note: "According to a report from Christchurch, motor agents in New Zealand, indeed throughout Australasia, are just now having difficulty with American motor car manufacturers owing to the latter endeavoring to force the importers to accept cars fitted with rims intended for straight-side tires in place of the standard clincher type."

Though our contemporary does not appear to think this small note of much importance, it is really a tiny cloud on the horizon foretelling the storm to come. It will be noticed that the term "standard clincher type" is used. This, of course means standard by custom and not standard in the sense that the S. A. E. standards are accepted ones.

So far as America is concerned there is little doubt that the straight side tire will be standardized by the society for nearly all the common sizes. If it were not for Ford cars the straight side type would probably displace the clincher pattern entirely. Of course the society has taken no action as yet, but the first meeting of the new tire and rim division of the standards committee showed that the tire makers are fairly well agreed as to the straight side being a *better* tire than the clincher. The straight side is likely to become standard because manufacturers of automobiles and the public are asking for it, not because the tire makers want to push it.

There are arguments both ways, but the straight side construction is certainly more mechanical than the clincher. The material which forms the casing, fabric cords or canvas as the case may be does not in the straight side tire, have to be bent and compressed into a close, hard formation in order to obtain an attaching bead. Instead it lies in a more natural position when the stresses upon it are examined.

Straight side tires have been known in Europe, they were used quite frequently about 1905, but the rims provided for them were mostly inconvenient, having a prodigious number of nuts and screws, so that changing a shoe was more trouble with a straight side than a with a clincher, for the soft bead clincher is easy enough to handle once the knack has been mastered. It so happened that the leading French and British tire makers preferred the clincher, because they were manufacturers of cycle tires first, and modeled their automobile sizes directly upon their cycle practice.

No doubt Europe will be slower in taking up the straight side type of tire again than America has been, but if a few years' experience proved that American tire makers and American automobile manufacturers and users are correct in their present belief that the straight side is the better design, the European tire makers will soon start making straight side tires to fit imported cars.

In Europe there has never been any real standards for pneumatic tires and it has always been realized that there are too many sizes in the metric schedule. The possibility of reducing the number of sizes has often been discussed, and there is no doubt that action will be taken some day in the not far distant future. When this day comes the European committee appointed to investigate the subject will certainly find it necessary to give close consideration to the straight side tire, as a very large number of cars have already been exported from America with straight side rims, and many more will be in the next year or two.

Sun Adds Four-Passenger Roadster

THE 1917 clan of four-passenger roadsters has another member in the new Sun light six. The new body has low, sweeping lines, a sloping windshield and a double cowl.

The front seats are divided with a generous passageway. The rear seat is built to seat two comfortably and allow plenty of leg room. The backs of both seats are high enough so that the passenger's shoulder has a support. Turkish rocker springs are used in the upholstery.

The compartment in the rear deck is sufficiently large to accommodate a couple of suit cases with room left for other touring necessities. The door is conveniently located at the extreme end of the deck, making an easily accessible carrying space.

There is a one-man top with Jiffy curtains. This top is provided with a visor that seals the front of the top with the top of the windshield, preventing rain from dripping in on the passengers. This four-passenger roadster is one of the five 1917 models built by the Sun Motor Car Co., Elkhart, Ind., including a five-passenger touring, a seven-passenger touring, a two-passenger roadster and a five-passenger sedan, all on the 116-in. wheelbase chassis.

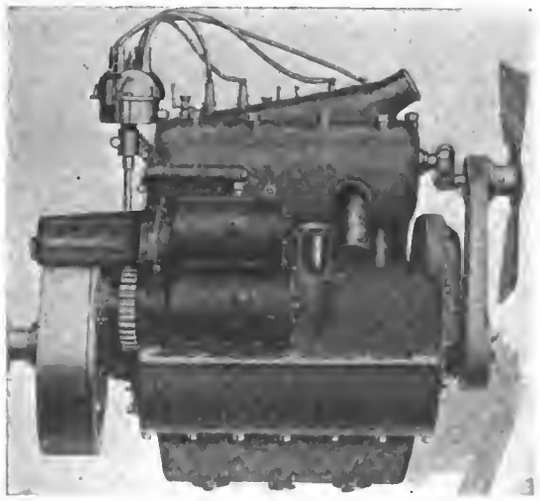
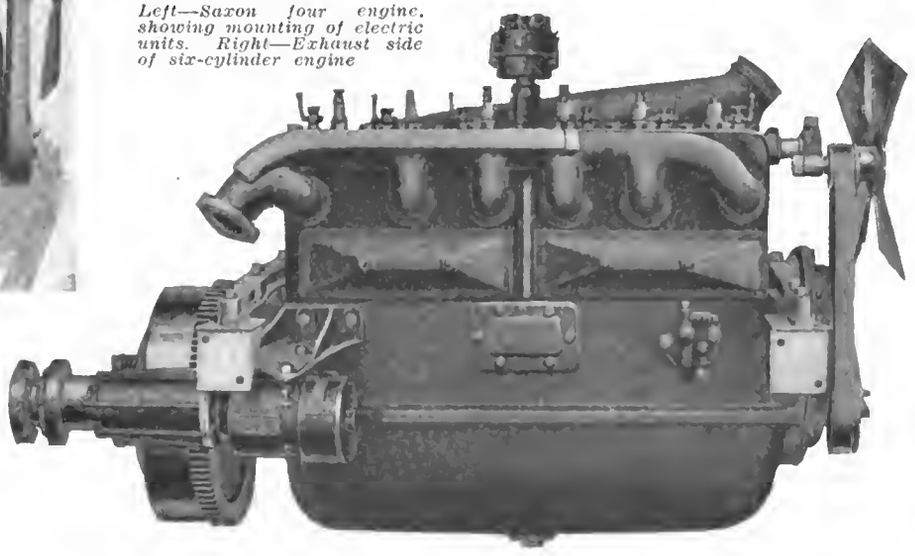
New Saxons Improved in Design



Four Now Fitted With Electric Systems, Demountable Rims and Larger Tires— Six Is More Roomy — Better Bodies

Left—Saxon four engine, showing mounting of electric units. Right—Exhaust side of six-cylinder engine



MARKED improvements over the previous series distinguished the new Saxon six and the little four-cylinder roadster. Refinements both in the mechanical details of the power plants and chassis, and some important body changes make the cars better in performance as well as in appearance, the six remaining at $815, and the roadster selling in its new form for $495.

In this four-cylinder roadster model, which was the first type of car to bring the Saxon name into prominence, the equipment has been materially increased, and the body revamped to accord with latest ideas. It is true that the cost of the roadster has been increased, and while on the face of it, it would appear that $100 has been added to the price, it is really more of a value than heretofore when the added features are taken into consideration. In the new series, this model is supplied only with full electrical equipment, including a two-unit Wagner starting and lighting system and electric head and rear lamps. Then, too, the size of the tires has been increased from 28 by 3 in. on Q-D rims to 30 by 3 Goodyears on demountable rims. These two important equipment additions, together with an electric horn and a speedometer, lift the Saxon four to an equal plane with any other automobile in the matter of completeness. Last year a starter was furnished for this model at an additional cost of $50, bringing the total then to $445, and when this is considered, the new price, with every modern feature and a number of refinements not yet mentioned, is a different matter.

The six is a decidedly better looking car than its predecessor, although that car was a most attractive appearing vehicle. It has a somewhat altered body line to bring it into accord with present-day body fashions, the popular straight-line effect being well carried out. Being 4½ in. longer; wider and in every way more roomy, and having a slanting windshield and new style crowned fenders, the new model takes its place among the distinctive cars of the season, reflecting much credit upon the designers who were able to impart so many added features without increasing the purchase price.

In addition to added comfort due to softer and deeper cushions, the new six is fitted with new cantilever springs which are of the full cantilever type. In the previous model, the springs were of the half cantilever type at the rear and measured 30 in. in length. In contrast, the new rear springs are 41½ in. long, trunnioned to the frame in the middle and mounted under the axle tubes at the rear. This form of springing is undoubtedly one of the easiest riding arrangements yet devised, and it does a great deal in increasing the easy riding qualities of the Saxon six. The front springs remain of the semi-cantilever variety, 27¾ in. long.

Crankshaft Is Larger

In the six-cylinder engine, several changes are to be found, perhaps the most important of which is the increase in the size of the crankshaft to a diameter of 2 in., which is really large for an engine of this size—2⅞ in. bore by 4½ in. stroke and developing from 30 to 35 hp. This new shaft has been well balanced, and with its added rigidity it makes for a very smooth-running power unit free from crankshaft vibratory nuisances. Another important engine change in the six is the shifting of the carbureter from the left or valve side to the right side where it attaches directly to the cylinder block, and the gas passages are cored within the casting. Heretofore, the carbureter occupied a position on the left.

Two-Unit Electric System

As on the four, Wagner starting and lighting system has been adopted, the new system being a two-unit outfit, with the starting motor carried on the right rear, so as to temporarily gear to the flywheel teeth for starting; and with the generator placed on the left side and driven by silent chain connecting with the crankshaft.

There is a change in the ignition also, the Remy distributer replacing last season's make, though placed in approximately the same position on the right side of the engine and driven by gear connection with the camshaft. To make the valve springs still more serviceable, they are now made of

chrome-vanadium steel, rendering them almost immune from fatigue, and though a refinement that does not show, they are really a feature of utmost importance when the durability of the car is considered.

Another chassis change on the six is the increasing of the brake drum size from 11 to 12 in. diameter, a feature that cannot be too highly commended when the safety factor is considered. Many an accident could have been prevented if the cars involved had been fitted with more powerful brakes. Here is a point of chassis design which the engineer should overdo rather than take chances of smaller brakes doing the work.

Two other new features that add to the appearance of the six are the grouping of all of the instruments in a plate on the cowl dash, and the fitting of a new style of top having more of a curve at the rear. This top possesses what is called a Grecian rear bow, and it is surprising how much this one thing adds to the machine with the top up. The four-cylinder model is also fitted with this form of top.

Details of the Six

As previously, the Saxon six chassis has a wheelbase of 112 in., and runs on 32 by 3½ in. tires, non-skid in the rear.

On the testing block, the engine delivers 34.7 hp. at a speed of 3200 r.p.m., which indicates that it justifies to the advertised rating of 30 to 35 hp. The dimensions of 2⅞ by 4½ in. give a good relation between the bore and stroke, and among the first impressions one gets when looking at this power plant is the compactness of the whole thing. The cylinders, cast in a block, are integral with the upper part of the crankcase, which carries the bearings, thus insuring correct alignment between the shafting and the cylinders and also making for rigidity. The cylinder head, carrying a large water outlet connection, spark-plugs, petcocks and fan bracket, is removable for cleaning of the valve chambers, valves, cylinders and pistons. The lower half of the crankcase, carrying the oil reservoir, is a steel pressing that is light in weight.

As already explained, the only exposed manifolding is that of the exhaust system, this being on the right. Below it are the two pressed-steel covers that go over the valve compartments, inclosing the tappets and springs in the usual manner against dirt and preventing undue noise.

Aside from the increase in the crankshaft size, there is no internal change of note. The valves have a diameter of 1 7/16 in., and have nickel-steel heads welded to carbon steel stems, a feature of the valve assembly being the long guides in which the valve stems operate, this preventing undue wear and making a smoother operating valve. As heretofore, each piston is fitted with a Burd high-compression ring at the top, below which are two eccentric rings of conventional type.

Ignition Wiring Manifold Fitted

In connection with the adoption of Remy battery ignition, it might be mentioned that an ignition wiring manifold has been fitted, this attaching to the exhaust manifold, and running in such a way as to prevent the wires from dropping onto the hot pipe. The spark plugs are placed over the intake valves so that they are not subjected to the great heat that they would have to undergo if they were over the exhausts where they would get the hot gases sweeping past.

Combination force-feed and splash lubrication is continued, oil being pumped to the individual splash troughs under each connecting-rod and also to the timing gears at the front. From the troughs it is splashed onto the various bearing surfaces by the connecting-rod ends, and finally gets back to the reservoir. There is an oil pressure gage on the dash, and a level indicator on the side of the crankcase.

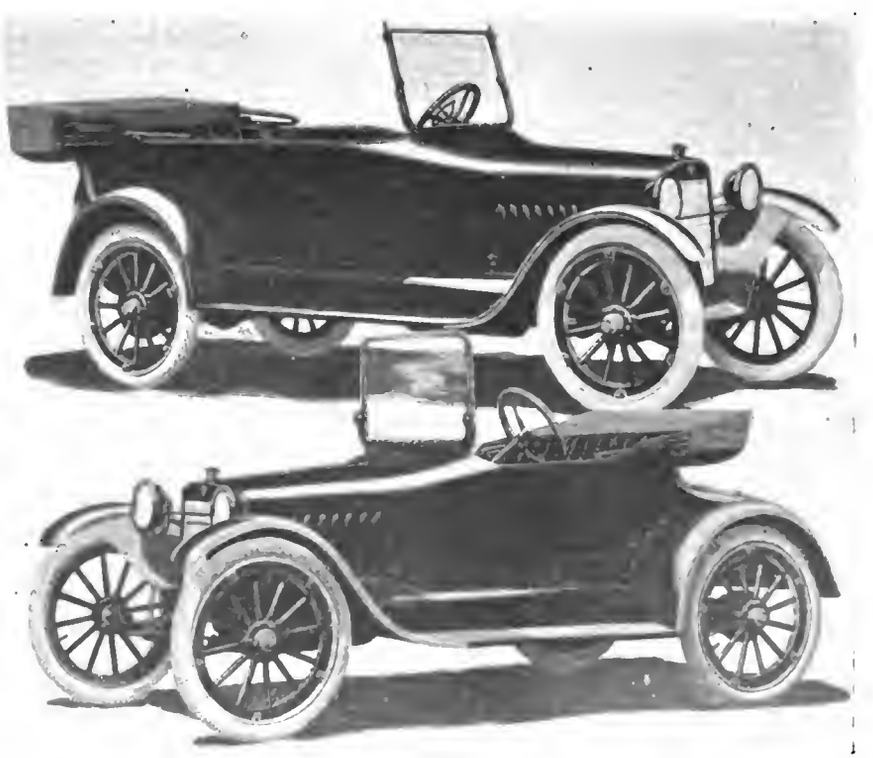
Back of the motor there is a dry-disk clutch housed in the flywheel, and then the power is transmitted through a universal joint to the propeller shaft. This shaft is inclosed within a torsion tube having a yoked front end that hinges to a frame cross member. The gearbox, containing the usual three forward and reverse gear changes, is mounted in unit with the rear axle, and between the rear end of the torsion tube and the front of the axle housing.

The rear axle is Timken, and has a pressed-steel housing that is very compact in design. The differential is of the two-pinion type, which is a factor for lightness, and it is carried on Timken roller bearings, as are also the rear wheels. Constructed of special steel stock 1 1/16 in. in diameter, the axle drive shafts are amply strong for the work they have to do. The driving gears are of the now quite generally used helical-bevel form, in which a rolling action is imparted to the mating gear surface, reducing gear noise to the minimum and because of greater tooth contact, strengthening the driving connection between the ring gear and pinion.

Saxon uses a pressed steel channel section frame of good proportions in this car, it having a channel depth of 4 9/16 in , width of flange of 1¾ in., and 5/32 in. stock. It is tapered to support the body in good manner, and has ample cross bracing so that there should be no trouble due to frame distortion from any cause in normal usage.

The Four-Cylinder Model

Like the six, the Saxon four also has a new body shape, and with its complete equipment, it is indeed an attractive little car. The increasing of the diameter of the tires by



Above—Saxon six-cylinder five-passenger touring car for 1917, showing the new streamline body and slanting windshield. This car lists at $815.
Below—Four-cylinder Saxon roadster, giving an idea of the improved body lines and larger tires. Fitted into a two-unit Wagner starting and lighting system and demountable rims, it sells for $495

2 in. gives a higher standing car with more road clearance, an advantage to be appreciated. The front axle clears the road by 11½ in., while there is 9 in. clearance at the rear axle. Another factor in connection with the larger tire equipment is undoubtedly important, this being the great excess of tire strength as compared with car weight, a fact which should reduce the owner's tire expense to a very considerable degree.

The new roadster appears with a change in the carbureter equipment also. The new Reichenbach atomizer type of instrument replaces the make used heretofore, finding about the same location, however, on the left side.

Comfort a Feature

Much thought seems to have been given to the matter of comfort in this new four, for with the wider seat and better upholstery, it is indeed on a par in riding qualities with its more complete fitments. The seat has a depth of 17 in. and is 40 in. wide, and a distance of 30 in. has been obtained between the heel board and dash. Doors also are amply wide, measuring 18 in. across. With the coming of electric lights, fitted with means of dimming for city driving, the side oil lamps have disappeared from the sides of the windshield, a change that will be appreciated.

The Saxon four has a 2¾ by 4 in. engine that is very similar to the six in general design. The cylinders and crankcase are integral, with an oil reservoir forming the bottom of the power plant, and the cylinder head detachable as a unit. The crankshaft has two large bearings, and is inserted through the end of the crankcase, which is of the barrel type. Internally the engine is conventionally designed with all parts substantially built. An output of 18 hp. is claimed for the unit.

This model has a dry-disk clutch in the flywheel, and the drive shaft is inclosed, a single universal joint being fitted ahead of the torsion tube. The gearset is interposed between the propeller shaft housing and the rear axle, and it has three speeds ahead. The wheelbase continues to be 96 in., and cantilever spring suspension is retained front and rear without change.

Overland Pumps Water Off 5 Acres

WHEN the ranch of J. L. Luck, near Los Angeles, Cal., became flooded recently, Mr. Luck used his Overland touring car to pump the water off 5 acres. The accompanying illustration shows how the rear wheel of the car was jacked up and attached to the pump handle by a hard wood block clamped to the rim, bolts being run through the space between the spokes to a block on the other side of the wheel. To this attachment the shaft was bolted and the engine started, the engine being run at a speed equivalent to about 5 m.p.h. on the road, this keeping the pump handle working forward and backward at a regular and effective pace. Three or four days' pumping drained the pool about the ranch house.

Maxwell Elite Model

THE illustration at the right shows the convertible roadster touring type body fitted to a standard Maxwell chassis by Harry J. De Bear, manager of the New York branch of the Maxwell Motor Sales Corp., and known as the Elite model. This car, which follows foreign tendencies in design, seats either two or four comfortably, the rear seat being accessible through the front door, as the right front seat folds forward to permit passage to the rear. The car is painted battleship gray and trimmed with red patent leather.

Two New Convertible Chandler Models

Four-Passenger Coupé and Seven-Passenger Sedan Are Mounted on Standard Six-Cylinder Chassis — Limousine Is Improved in Design

The new Chandler limousine and a view of the driver's compartment. Below—The four-passenger convertible coupé

THE Chandler Motor Car Co., Cleveland, Ohio, is prepared to give much more attention to closed body styles for winter use than a year ago and expects to manufacture from 750 to 800 closed jobs consisting of convertible types and limousines.

The Convertible Coupé

One of the newest closed jobs is the four-passenger convertible coupé at $1,895. The body is a Springfield design with the same seating arrangement as the present roadster, namely, a cloverleaf pattern with a wide rear seat accommodating four persons comfortably. The seating arrangement is more roomy than in the roadster as the baggage compartments at the sides have been removed and the space used in the seat. There is also more leg room; the glass sides are entirely removed and carried in a rear compartment, standard exterior body finish is in blue; the windows in the doors lower by straps; there is a door at either side; lighting is by a dome bulb; and the interior finish is a new blue weave with a small and quiet pattern.

The same tire sizes are used as on the runabout, and gear ratio and other chassis specifications are standard. Deliveries will start Oct. 1.

A Convertible Sedan

The other convertible is a seven-passenger sedan model at $1,895. The body is a Springfield job with the usual side windows that may be removed, giving an open body effect.

The limousine is quite improved over a year ago, so much so that it can be designated a new model listing at $2,595. There is capacity for five in the rear. The two auxiliary seats face forward and swing forward and down into compartments in the back of the front seats. The interior finish is simple yet effective, a feature being a 5-in. mahogany panel across the center of the door and around the compartment. An option is given on interior finish, four colors being offered.

Door windows are raised and lowered by patent openers and the glass back of the driver is made in halves which slide right and left past each other in place of being raised or lowered.

Chandler production last year was 6400 cars. This year it reached 15,000 cars and next year the figure aimed at is 20,000.

—

$15,000 in Prizes for Grand Prize and Vanderbilt Cup Race Winners

FIFTEEN thousand dollars will be the prize money paid to the winners of the Vanderbilt Cup and Grand Prize races to be held on the Santa Monica road race course in November. Each event will carry $7,500 in prizes divided as follows: First prize, $4,000; second prize, $2,000 third prize, $1,000, and fourth prize, $500. In addition the winner of the Vanderbilt Cup race will receive the William K. Vanderbilt, Jr., cup and the victor in the Grand Prize classic will receive the $5,000 cup awarded by the Automobile Club of America.

The FORUM

French Emissary Excluded from American Bearing Plants

By George L. Moskovics

Mechanical Engineer, George Automatic Roller Bearing Co.

THERE visited this country recently the representative of a large French organization, making automobiles, trucks and accessories. This gentleman was especially interested in the American methods of ball and roller bearing manufacture with a view to introducing in France some of our modern high-production, high-precision machinery and methods.

He was not trying to obtain any so-called secret information, except as the possessors thereof would be willing to sell their information under license, etc. In view of the way in which foreign manufacturers have always received representatives of American companies in their plants, he looked forward to no difficulty whatsoever in obtaining permission to inspect such parts of our American plants as were not kept closed to the public.

Much to the surprise of this gentleman, he was refused permission even to go over the more public parts of the great majority of our bearing plants, this refusal in some cases being none too courteously given. The result of such a narrow-minded policy of exclusion may be judged by the following quotation from letters, written by the gentlemen referred to:

"It was really very foolish of these people not to let me see the interesting features of their works, considering I wss prepared to purchase anything that was worth the trouble. I was prepared to buy any process, machine, patent or license that may have been interesting to my company. Furthermore, as we cannot find the machinery we need in France, we were willing to give our orders to any concern that would be interested. As it stands now, we don't need them any more and will soon be prepared to enter into competition here and abroad. I think our people in France will let no more foreigners go over their works."

Disregard of Consequences

In view of the commonly recognized fact that when Europe gets on her feet after the war we are going to have a hard scramble to compete with her in the face of the great lesson of efficiency she has learned, it strikes me that we are not building very securely when we treat her emissaries in such a cavalier manner as this.

Tractor Requirements for General Farm Use

By John Lefler

HEREWITH I am sending you some views on the tractor question as I see it, in THE AUTOMOBILE.

First as to size. It seems to me that for the man who can get his work done with a two-horse team it would not be profitable to change; but for one who has a little more than two horses can do or enough for four horses or more a part of the time, or all the time, it might pay him to make the change rather than to maintain two extra horses in idleness at a continual expense. A 4-hp. size then will probably be the most popular. This seems to be about Henry Ford's idea.

Second, the wheels will have to be shod with rubber tires or some successful substitute for rubber tires, a tractor will have to haul the farmer's crops to town as well as doing the plowing and cultivating, and the use of drive wheels with calks or grouters on them will be very destructive to good road surfaces either dirt or stone.

Third, it should have a comfortable seat for the driver. After a man has paid $1,000 or so for a machine he is entitled to something better than a mowing machine seat to ride around on.

Fourth, as to rating, the plan of rating a machine by the number of horses it will replace is not far wrong from a farmer's viewpoint. If a tractor manufacturer rates his machine as a 6-12 or 10-20, etc., this is intelligible enough to a farmer. He undestands by that, that the engine will do the work of six or ten horses and will operate as a gasoline engine at 12 or 20 hp. to drive feed cutters, pumps, thrashing machines, etc., we will leave that question of torque and ratio and drawbar pull in foot-pounds to the engineers.

Filter Dust from the Air

By Chas. E. Duryea

J. EDWARD SCHIPPER'S article on U. S. Trucks in Mexico calls attention to the need for air filters to take the dust out of the air before it passes into the engine cylinders. It seems hopeless to again refer to this matter for it has been before the public time and again since early days. If the air is passed through a bag, such as is used on the small vacuum cleaners for household use, it will leave all its dust behind.

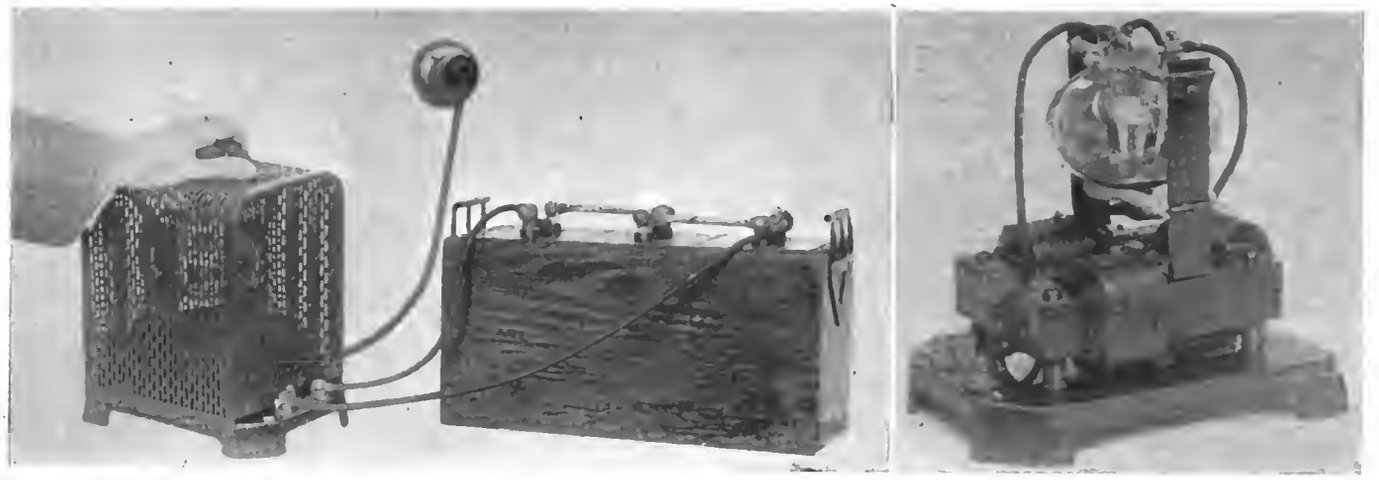
Must Be Washed

Several car makers fitted such screens or strainers at the beginning of the industry but users generally left them off after they became so clogged that running was not good. The right way is to send them to the wash every week just as one does one's clothes. Some users protest that an air filter lessens the amount of air the engine can get but this is not true appreciably until the cloth has filled with dirt. The small vacuum cleaners produce but a very slight vacuum and use a very close woven cloth, for milady will object if there is a smell of dust in the air. The engine suction will get air through a considerable resistance. I have been unable to notice any difference if the bag is fairly large.

Electric Omnibus Cost Averages 9 Cents Per Mile

IT costs 9 cents to run an electric omnibus a mile, according to the York Corp. Tramway Department, England. This organization has had over a year's experience with four electric omnibuses and finds that after a total mileage of 65,470, this is the resultant figure. Making some additional allowances for maximum tire maintenance, etc., this may be brought up to about 11 cents per mile excluding standing charges.

An interesting feature of the method of carrying out this work is in the charging stations at the terminus of the route. The charging cable with plug attached is drawn up from the roadway box and connected to the bus. A small door is opened, a button pressed causing the machine to start up and commence charging. A second pressing of the button shuts down the plant.



Left—Charging a storage battery with the G. E. small mercury arc rectifier. Right—Rectifier with cover removed

A Rectifier for Battery Charging

G.E. Small Mercury Arc Type Is Portable and Can Be Used To Charge the Battery in the Car

A SMALL mercury arc rectifier for charging starting, lighting and ignition batteries has been placed upon the market by the General Electric Co. of Schenectady, N. Y. The device is handy in size and easily portable, being rectangular in shape and of about the same bulk as a three-cell storage battery.

This rectifier is designed for charging one three-cell, one six-cell or two three-cell batteries, or it can be connected to a single battery cell and will charge it at approximately 6 amp. when connected to a 110-volt alternating current supply. The rectifier is made for 133, 60, 50, 40, 30 or 25 cycle, 110-volt alternating current circuit. The prices vary between $25 and $31.25.

Partial Discharge Shortens Battery Life

While long trips through the country help to keep the battery in condition it is stated by the General Electric Co. that periods of city driving with the many demands for starting, the horn and often for lights, tends to exhaust the battery while the low speed demanded by congested traffic holds the engine below the charging speed on the generator. These conditions of partial discharge tend to shorten the life of the battery if they occur frequently or for long periods. It is for this reason that this device has been brought out as a supplementary method of charging. This rectifier is marketed under the name of type MS form K. It will deliver 5 amp. at a maximum of 15 volts, direct current when connected to an ordinary lamp socket.

When charged, the positive plate of a storage battery cell contains peroxide of lead and the negative plate is metallic lead in its spongy form while the electrolyte or liquid is sulphuric acid at its highest specific gravity, 1.280. If the battery is then discharged to the normal limit, a large proportion of the peroxide of lead becomes lead sulphate, through the action of the acid. The negative plate too now carries lead sulphate and the gravity of the acid drops to about 1.170 (practically water) with few of the original characteristics of the acid left. The acid loses its identity through creation of the lead sulphate.

Charging as Needed

When the battery reaches this stage, it should be charged by the application of "direct" current properly adjusted as to voltage, for some hours depending on the amount of current drawn from it. In addition, about every fifth or sixth recharge a so-called "scouring" or "soaking" charge at a low current rate should be put in to bring the electrolyte up to full specific gravity and to remove all traces of the sulphate, etc.

Lead Sulphate Broken Up

In the processes of recharging, the lead sulphate on both plates is "broken up," to use the chemical phraseology, while the liquid resumes the characteristics and specific gravity of sulphuric acid. At the the same time the voltage across the terminals rises with the gravity of the electrolyte.

No harm will result to a battery as long as there is plenty of lead sulphate for the current going into it to work upon, but the necessity for close regulation of the current arises when the lead sulphate had nearly all been returned to its original form. Then the current tends to break the water into its component parts, hydrogen and oxygen, which causes gas and heat. If this condition is permitted to continue for any length of time it will ruin the battery.

This method of regulation has been devised to prevent such an occurrence.

Can Charge Battery on Car

The rectifier consists of a metal base on which are mounted the necessary reactance coils and rectifier tube in a suitable holder. The whole device is covered with a sheet metal cover. An attaching plug is supplied which may be inserted in any lamp socket. There are also two binding plugs marked plus (+) and minus (—) from which wires are run to the battery or batteries to be charged. The device weighs about 15 lb. and is easily moved. It is not necessary, therefore, to remove the battery from the car to charge it.

Tipping the rectifier slightly after connecting the two terminals of the rectifier to the battery and the rectifier itself to a lamp socket, will start it and no further attention is necessary until the battery is charged and the current shut off. Two batteries may be charged at the same time by connecting them in series, and connecting the rectifier to the extreme terminals of the batteries. In case the current is interrupted the batteries will not discharge back through the rectifier. At 10 cents per kilowatt-hour for a 10-hr. charge, it will cost about 15 cents for charging any of the batteries above enumerated.

The Rostrum

Power Delivered Through Outside Wheel

EDITOR THE AUTOMOBILE:—When a car turns a corner one wheel travels faster than the other; is the power all in one wheel or is there still an equal amount of power in both wheels, and if the power is all in one wheel while the car is turning the corner, which wheel is the power in?

Oklahoma City, Okla. D. J.

—In rounding a corner which is of such a radius that the inside wheel is stationary all the power would be delivered through the outside wheel. When the other extreme exists, that is, when the car is traveling along the circumference of a circle of infinite diameter, in other words, a straight line, both wheels are delivering the same power. Between these two extremes the ratio of power delivered varies with the ratio of speed of wheel travel. This becomes quite evident if it is considered that both wheels carry the same load, and hence the wheel which carries the load furthest is exerting the greatest power.

F. R. P. Chassis Suitable for Racing

Editor THE AUTOMOBILE:—Would an F. R. P. make a good racing car without many changes?

2—What is the highest speed made by an F. R. P. stock chassis?

3—Did the Packard Special driven by J. G. Vincent at the Sheepshead Bay Speedway have a specially-built engine?

Tacoma, Wash. E. V.

—The F. R. P. car would make a good racing car without many changes.

2—It is capable of 100 m.p.h. with the two-passenger body and 80 m.p.h. with the seven-passenger.

3—The Packard Special driven by Mr. Vincent had a special aeroplane engine which is entirely different from that used in the Packard stock chassis.

Toeing in the Front Wheels

Editor THE AUTOMOBILE:—If the front wheels of an automobile toe in slightly, by this meaning that the measurement between the felloes of the wheels when taken on both sides of the axle would not be the same, would this cause any excessive wear on the front tire? We understand, of course, that a slight dishing of the wheels would have no effect on the wear, but the other point is not clear in our minds.

Minneapolis, Minn. W. S. N. Co.

—Toeing in of the front wheels will tend to cause a slight sliding action of the tires over the road. This tendency, however, is offset by the castor effect given the wheels and by the added ease in steering.

Buick Air Pipe Now Shorter

Editor THE AUTOMOBILE:—Why does the Stewart feed on the Buick 45 have the air pipe extend from the feed to the dash? This is a great deal of extra copper tubing unless it is done for some purpose.

Lawrence, Mass. C. E. C.

—The reason that the Buick 45 had a long air pipe was to prevent the leakage of volatile gases through evaporation. With the heavier grade of fuel now employed the practice of carrying this pipe up to the dash has been discontinued and the Buick company is now simply bending it over to one side of the tank. They have found that with the present rate of fuel there is practically no danger of the volatile products escaping by means of this vent.

As you are no doubt aware, the grade of gasoline generally marketed has been growing steadily heavier and less volatile. Hence it is no longer necessary to take the same elaborate precautions as were essential when the fuel used was considerably lighter and more dangerous to handle. It has also resulted in an entire revision of the methods of carburetion.

Formula Rating of Ford is 22.5 Hp.

Editor THE AUTOMOBILE:—Will you kindly state the horsepower of the Ford engine according to the S. A. E. rating and explain how this rating is computed?

2—At what r.p.m. does the Ford engine develop its maximum power?

Timberville, Va. W. B. F.

—The horsepower of the Ford car is 22.50, as the bore is 3¾ in. This formula is $\frac{B^2N}{2.5}$ where B is the bore and N the number of cylinders.

2—The peak of the Ford horsepower curve is at 1600 r.p.m.

Data on Expansion of Metals

Editor THE AUTOMOBILE:—Kindly give me the relative expansion of metals used in automobile construction at the following temperatures, using Fahrenheit unit. 212, 300, 400, 500, 750, 1000, 1500, 2000, 2500 and 3000.

2—Please state at what point of temperature lubricating oils are burned, light, medium and heavy oils? That is to say, at what point would these three oils become ignited when brought in contact with heated metal?

Mt. Vernon, Ill. E. E. E.

—Cast iron expands 0.00000556 times its length for every degree rise in temperature on the Fahrenheit scale. Babbitt metal has the co-efficient of expansion of about 0.00000986. Steel expands at about 0.00000689.

2—The fire point of these oils is around 450 deg. Fahr. for the light oils, running up to about 500 for the heavy.

Adjustable Pedals on Many Cars

Editor THE AUTOMOBILE:—What car selling under $1,000 has the most comfortable seating for driver who is 6 ft. 3 in. tall?

Roselle Park, N. J. C. E. M.

—Any of the cars that have adjusted pedals could be made to accommodate you, provided that the cowlboard is not too low.

Carrying Two Spare Wire Wheels

Editor THE AUTOMOBILE:—How can I carry two Houk wire wheels with tires mounted on the rear of a 1916 Hupmobile touring car, the wheel carrying 34 by 4 shoes?

I would like them to look as much like the Mercer sport-

ing model as possible. Can you suggest where I could get tire holders to fit this car and be strong enough to carry the weight? I now carry one mounted wheel on a wheel carrier furnished by the Hupp company, but want to carry two wheels.

Alamo, Tenn. R. W. F.

—At the present time the Houk Mfg. Co., Buffalo, N. Y., can furnish a double hub which can be bolted to the bracket on the rear of your car in place of the single hub now attached. This double hub will carry either one or two wheels. Before attaching this double hub the bracket in the rear of the hupmobile should be raised a trifle so that the hub will be parallel with the ground.

Should you not care for the double hub arrangement, a cradle suitable for carrying two wheels can be obtained from practically any supply house. The brackets on these cradles can be made so that they will fit any car.

Removing Scale from Radiator

Editor THE AUTOMOBILE:—Please give complete directions for removing scale and other deposits from the radiator of an automobile.

I have seen general directions, but they never seem to be complete. If sal soda or soda ash is used, please state how much per gallon and under what conditions to use same, how long it should be left in the radiator, etc?

Uniontown, Pa. E. T. P.

—Scale can be removed from radiators by using a saturated solution of common washing soda and water. Thoroughly flush the radiator out with the solution then clean with fresh, pure water. A mixture of ordinary washing soda in which 4 oz. is used to the gallon of water will do the work properly.

Wiring and Connections of Allis-Chalmers

Editor THE AUTOMOBILE:—Can you inform me about the wiring and principle of operation of the cut-in and regulator of an Allis-Chalmers electric system as installed on a Grant six?

2—Kindly give reasons why the fuse on this same system should blow when the engine speed reaches 200 r.p.m.?

Windham Junction, N. H. A. A. W.

—A full wiring diagram of this system is given in Fig. 1. This shows both the internal and external connections of the entire system. The regulator is a vibrating type and the mechanism is clearly illustrated in the drawing. As shown, there is a lead from the battery around an armature winder, then through the cutout contact and over to the generator. When the current from the generator becomes strong enough to overcome the tension of the spring on the cutout contact piece the battery starts charging. When this current falls below that strength the cutout is open. The vibrator throws a resistance into the circuit of the shunt field every time the charging rate increases above normal. As soon as this resistance is thrown into the field the current drops, thus automatically regulating the charging rate.

2—In the particular case you mention it is probable that the small contact inside the starting switch is not making good connection, or that the vibrating regulator contacts are stuck, or both. If the small contacts inside the starting switch are not making good connection it opens the charging circuit. As the regulating contacts do not start to vibrate until the charging current rises to about 10 amp., these contacts will remain closed, putting a full field on the generator with no load. The voltage and field current will then rise to a high enough value to blow the fuse. It is very possible that the contacts carrying this high field current may fuse and stick before the fuse itself blows, as this has frequently been known to happen under conditions which are similar to those you have described.

To remedy the trouble the bottom of the starting switch could be removed by unscrewing it and contacts cleaned and the tension of the spring adjusted so that the small contact makes good connection. If the fuse continues to blow after this has been done, the regulator should be replaced with a new one.

Oiling the Clutch on 1917 Paige

Editor THE AUTOMOBILE:—I have a 1917 Paige with a multiple disk cork insert clutch and have been using 600 W oil which will run for a while and then gradually run out into the pan, causing the clutch to slip.

2—Kindly advise if this is the correct oil to use and if it is possible to correct this oil wastage.

Cumberland, Md. L. S.

—The clutch compartment of the 1917 Paige should contain 1 pt. of a very light grade of lubricating oil and during the Winter months it would be well to mix this with one-third kerosene. This compartment should be drained at least once a month, washing it thoroughly with kerosene or gasoline and refilling with fresh oil or the same oil may be used, providing it is strained.

2—600-W oil will not only be wasteful, but will prevent proper operation. It would be well to drain off this oil, making certain that the compartment is washed out thoroughly and it will pay you to be sure to use nothing but a very light grade in the future.

Horsepower and Pulling Power

Editor THE AUTOMOBILE:—Suppose two automobiles each weigh 2600 lb., one having a horsepower of 25 and the other 26; about how much more weight would the 26 hp. one move at usual driving speed than the 25-hp. car? Would it be as much as 500 lb.?

Rochester, N. Y. W. A. P.

—Assuming that both cars had the same frictional losses in transmission of power and had the same gear reduction, the ratio of pulling power under most circumstances would be 25 to 26. It is impossible to give definite figures.

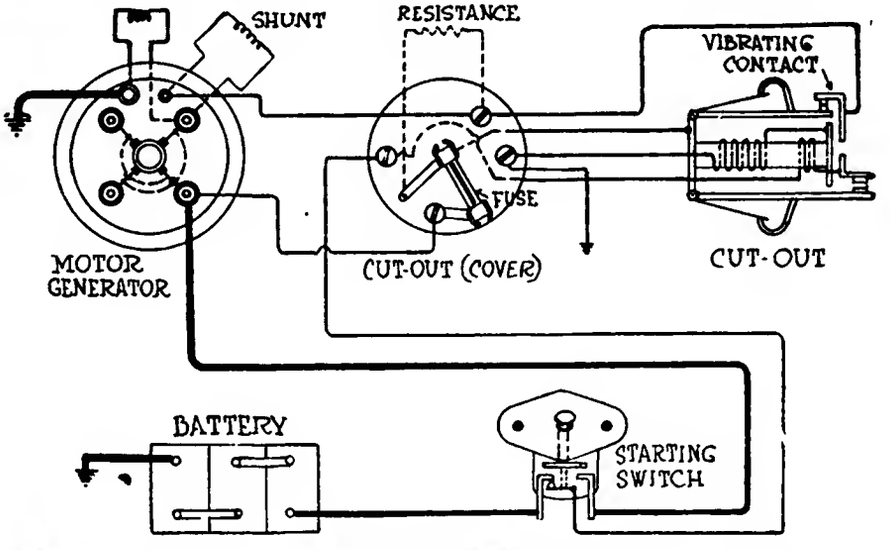


Fig. 1—Wiring diagram of Allis-Chalmers electric system as installed on six-cylinder Grant

Cleveland—Rising City in the Industry

More Automobile and Accessory Factories Have Been Added to Its Roster in the Past Year than to That of Any Other City—Many New Plants

CLEVELAND, OHIO, Sept. 23—The progress that Cleveland is making in the automobile industry is one of the topics of the day with manufacturers. Within the last year Cleveland's list of automobile and accessory factories has grown more rapidly than that of any other city, and each week brings announcements or rumors of other concerns moving to this city.

Within the last few months several new factories for automobile concerns have been built, and others are being built and arranged for at the present time. The Jordan Motor Car Co. located here some months ago and is now nearly at schedule production. The Grant Motor Car Co., Findlay, Ohio, has its new factory nearly completed and will occupy it in the near future. Within the last few weeks the Abbott Corp. of Detroit announced that it would locate here. A new factory is now in the process of construction for the Dann Products Co. of Chicago. Within the last few months the Denneen Motor Co., truck manufacturer, has located here and is now well under way with production.

Four H. A. L. Cars a Day

The H. A. Lozier Co., which started deliveries of the H. A. L. car last April is now turning out four cars per day and hopes to be on a schedule of six in a short time. The factory is located on the second floor of the old Royal plant and employs upward of 300 men. It is expected that the production for the fiscal year of April to April will be 1000 cars. Already a selling organization covering approximately half the country and embracing upward of forty dealers has been organized.

Baker-R. & L. Progress

The Baker-R. & L. Co., which a year ago secured a license for the manufacture of Owen-Magnetic cars, started the delivery of these early last Spring, and has now an output of sixty cars per month, and which is being increased each month. The electrical transmission systems for these are manufactured in the Fort Wayne plant of the General Electric. All bodies, including closed types, are built in the R. & L. plant, the company at present building closed types ranging from $3,500 for a coupé to $6,000 for a limousine. Optional colors are given at list prices. In the closed work much variety is given in upholstery, trimmings, etc. In addition to the manufacture of Owen magnetic cars, the Baker-R. & L. Co., is continuing its electric passenger vehicles.

Cleveland is admirably located as a railroad distributing center. It has excellent shipping facilities over the New York Central system and the various lines controlled by it, such as Lake Shore & Michigan Southern, and Big Four. It has every facility over the Pennsylvania lines, not to mention the many other railroad systems entering the city. This fact in itself is a big consideration with automobile shippers.

In addition to new concerns locating in Cleveland, the automobile and accessory industry has been growing rapidly. Many factory additions are at present under way and new plants are being built.

Willard's Great Plant

One of the greatest factory building activities is that of the Willard Storage Battery Co., which started its new factory 5 miles from the heart of the city 3 years ago and which it has since operated in addition to its old factory near the center of the city. At present the new factory is being quadrupled in size and when completed, in a few months, will have a capacity of 10,000 to 12,000 batteries per day. At present the capacity of the two plants is 4500 per day, with a working force of 2000.

The new factory is located in that section of the city known as Collinwood, which is served by the Cleveland Belt Line railroad, which furnishes ideal shipping facilities, Willard having switching accommodation of thirty-eight cars. The company has 16 acres of land, 10 acres of which are already built upon.

The new buildings now in process of construction will give every manufacturing facility. One building for the molding and grid pasting department measures 78 by 304 ft. Work is nearly completed on a special building for assembling and battery forming which will have 90,000 sq. ft. of floor area. The building is one story, 300 by 300. There is another building 85 by 200 to be used as an engine room and power house. When the new buildings are completed there will be a special one for the manufacture of batteries for train-lighting purposes which is a growing part of the work. It is hoped that by Jan. 1 all of the Willard work will be carried on in this new plant.

Every feature to hasten production has been looked after. It is a daylight plant all through. The wood working department where battery boxes are made has capacity for 10,000 boxes per day. In connection with these boxes all metal parts are lead plated, lead plating being a new process in which a coating of lead approximately 5/1000 in. thick is deposited on all handles, metal screws, wood screws, etc. By this means there is no deterioration or corrosion due to acid.

A feature of the new plant is an electric testing device for the different battery jars by which the smallest holes or thin spots can be detected. An alternating current of 24,000 volts is used in the test, which is proving so complete that the company replaces any jar in six months if returned to the branches or service depots.

An important department of the new factory is the die-casting division where all of the grids are manufactured. This department is housed in a long rectangular room down the center of which are twenty-four furnaces for heating the metal, and with facilities for four or five men with die-casting machines working from each furnace. Factory arrangements are such that the grids are transported but a short distance to the trimming presses where all of the surplus metal is punched off.

A novel feature is a smelter department in which all the good metal is reclaimed from the cleanings of castings, etc.

A Refrigerating Test Room

The new factory incorporates a refrigerating test room in which it is possible to test a manufacturer's engine with starting-lighting apparatus, battery, etc. The motor unit with battery, etc., is mounted on a heavy truck which runs on a track into the refrigerating room where a temperature of 20 below zero is maintained. The engine is controlled from the outside, so that it is possible to test the efficiency of the battery for starting all kinds of motors in this temperature.

In the grid pasting department motion study has resulted in the use of an endless belt which passes between the work benches of those pasting material in the grids. Once the grid is pasted it is placed on a traveling belt which carries it to other parts of the factory where the drying is done. Another example of labor economy is the use of eight Ellwell-Parker high-low industrial trucks used for transporting trays laden with plates, or other goods around the factory. In no part of the new plant has anything been left undone to economize labor and make working conditions better.

Air Changed Frequently

In the plate forming room, which is 140 by 300 ft. there is a change of air five times every hour and ten times if necessary. This is because of the gases given off in charging and forming the plates.

The factory is well supplied with automatic machines for the manufacture of terminals, bolts, and other small parts entering into the battery. There are other gangs of presses to stamp the handles of the battery boxes. On the boxes embossed lead nameplates are now being used. These avoid corrosion.

White on Double Shifts

The White company has been operating its factory on double shifts for the past 2 years. In its truck department it has had a great deal of European business but domestic trade has been exceptionally good during the past year. Factory additions are at present being carried out.

Winton Output Sold

The Winton company has increased its output over 1915 and is still one month behind in orders. Its 48 model is now in its tenth year, in other words for 10 years the company has been a devotee of six-cylinder design. Practically the entire Winton output is sold with different colors, color options being a part of every car sale. Thirty per cent of the output is sold with wire wheels. In all thirty-four different body styles are furnished, and 33 per cent of the business is closed winter jobs. Winter job business is one-half greater than a year ago. To take care of the various colors for the different bodies a very complete battery of drying ovens has been made a part of the factory equipment.

400 Stearns-Knights a Month

The Stearns company is busy on its 1917 production. During the fiscal year, July 5 to July 5, 3000 Stearns-Knight models were produced, 2100 four-cylinders and 900 eights. The present factory schedule is 400 per month, divided equally between the two models. There are 1400 men at present and since Dec. 1, the machine shop has been working three shifts per day. During the past year the factory has been enlarged by an assembly building 70 by 200 ft. five stories, and of cement construction.

Peerless Plans Expansion

The Peerless company is at present engaged on its European order of trucks calling for seventy 4-ton trucks per week which order will carry the factory into the Spring months. The factory employs 3000 men and in addition to its truck business is producing fifty eight-cylinder passenger cars per week. Factory enlargements are planned for the near future and will include three new buildings, one will be for the exclusive manufacture of passenger car work and will have 150,000 sq. ft. floor space.

Chandler Boosts Production

The Chandler company, which has had such a phenomenal growth has new enlargements under way which will give a capacity of 80 to 100 cars per day for the spring. One new four-story building 60 by 500 ft. will be built for general assembly work, and will be ready for spring production. In addition a special service building 160 by 160 and one story is being added.

Walker Mfg. Co.'s Shop

Many people have the misapprehension that Chandler is an assembled car, and that motors, axles, gearsets, etc., reach the factory as assembled units ready to be incorporated in the car. This is not so. All of these units, with the exception of the gearset, are not only assembled in the Chandler factory but the machining work is done in plants working specially for the Chandler organization. One of these is the H. J. Walker Mfg. Co., whose factory joins the Chandler. This Walker plant is a huge machine shop 120 by 200 ft. employing 500 men. Over $100,000 worth of new machinery is being added, and over $125,000 worth of new machinery was added in the last 6 months. Much of the Chandler machining is done in this factory but the assembling in the Chandler plant. Rear axles are entirely assembled in the Chandler factory as are front axles. In the motor testing department the twenty-eight testing blocks are constantly filled.

A Briggs Body Plant

Adjoining the Chandler factory is a small factory of the Briggs Mfg. Co., to take care of the Chandler bodies. The bodies are built at the Detroit plant of the Briggs company and the small Briggs factory adjoining Chandler is for final painting and trimming. This plant does nothing but Chandler jobs. The growth of the Chandler factory has been one of the most rapid in Cleveland. The factory was started in February, 1913, and the first cars were shipped July, 1913. Last year production was 8000, this year 15,000, and next year the figure aimed at is 20,000.

Jordan's New Plant Rushed

The new Jordan factory is at present producing six to seven cars a day and by Oct. 1 will be at its schedule of ten cars per day. The first car was turned out Aug. 14, and on Sept. 1, just two weeks later, the schedule was three cars per day. The factory is a new structure, 30,000 sq. ft. floor space. Ground was broken on April 5, and the factory occupied May 25. Between ninety and 100 men are working there at present. Sixteen chassis are going through assembly at the same time. The company has a good stock of materials on hand, upward of one hundred frames, and other materials in like proportion being on hand. The bodies are finished in two standard colors, maroon and green. The bodies are received at the factory minus the finishing coat, and two special body painters from the body company give them these final touches. Seventy-five per cent of the cars are shipped with wire wheels. The company plans to build 2000 cars and reports all but 129 of these already contracted for. At present there are thirty to thirty-five dealers.

Perfection's Committee Management

The Perfection Spring Co., one of the largest spring producers, has worked many changes in its factory organization and equipment during the past year. One of the most important of these is the introduction of the committee system's management in contrast with individual management of the different departments. There is an executive committee for the general management of which Christian Girl, president of the company, is a member ex-officio. Such departments as purchasing, sales, engineering, factory management, etc., etc., instead of being in the hands of an individual, are in the hands of committees. The system has been working for some months and is giving good satisfaction. Committee management, while new in the automobile field, is not new in the industrial world, and has been worked with satisfaction by many large organizations. There is a regular schedule of committee meetings, all taking place during office hours, and constituting a part of office work. Committees consist of three to five or more members according to the work.

One of the leading advantages of committee work is that broader consideration is frequently given to many factory matters. For example, in the purchasing department it might be possible for an individual purchasing agent to favor one firm over another, due to old friendships,

or other reasons, but such favoritism is scarcely possible under the committee system. The committee work has been carried to the extent of salary increases being handled by committee rather than by an individual.

The Perfection plant employs 1800 men who work in three shifts of 600 men to a shift. The plant has been working on a day and night schedule since July, 1914, and has been working on the three shifts of 8 hr. each since July, 1915. The factory output approximates 6500 springs per day and upwards of 125 tons of steel are consumed. During the past year the factory has developed. One building is a steel warehouse and the other a two-story structure 88 by 67 for factory welfare, hospital, and other uses.

Unit System of Spring Making

In its factory the Perfection Spring Co. has made many changes. One of the most important is the unit system of spring manufacture. In this system the factory is divided into rectangular areas, each area constituting a unit in spring manufacture. The capacity of each unit is one finished spring every minute of the twenty-four hours of the day, or 1440 springs per unit per day. At present six of these units are operated. Each unit can take raw spring stock from the stock room and have it converted into a completed spring in the shipping room in 4 hours. By this unit system of manufacture it has been possible to apply the latest efficiency factory methods. Motion study has largely entered into the work and three improvements have been incorporated into each unit. These improvements are all for conveyor systems of doing work faster. For example there are conveyor furnaces for heating the leaves of steel that go into the spring; there are conveyor ovens for annealing these leaves, and there are conveyor tables to hasten the assembly of the leaves together, forming the complete spring.

Strips Heated Slowly

In the conveyor furnaces the cold steel strips from which the leaves are formed are fed into the furnace at one side; they slowly travel through it, being heated as necessary, and come out at the other side red or white hot as necessary and ready to be bent or cambered into proper shape. If the grade of steel varies the speed of going through the furnace must also vary.

The conveyor annealing ovens operate on the same system.

The conveyor assembly table is a huge table along the sides of which are twenty-one men whose work it is to put the leaves together and add center bolts, clips, bushings for the eyes, etc. In addition to bringing parts together small milling operations such as bushing the sides of the eye are done. The leaves are also graphited.

Another feature added during the past year is a huge steel warehouse which is a separate building and into which all of the steel stock coming from the steel factories is placed. It is a huge building, 380 by 105, one story high, but measuring 42 ft. from the floor to the roof. From end to end, along either side of the central aisle, are central stacks of steel in flat bars ready to be cut into lengths for spring leaves. There is capacity for 80,000 tons of steel of this stock. Overhead is a huge traveling crane operating from end to end. This crane picks the steel stock direct from the railroad cars, which enter a bay in the side of the building. The stock is deposited where needed.

Along the center aisle are various electrically operated cutting machines which cut the steel stock into necessary lengths for springs. These cutting machines are on the central track and can be moved along to any point closest to the particular stock that has to be cut. The cut stock is then transported by electric trucks to the necessary parts of the factory.

Denneen Starts Delivery

One of the new Cleveland truck concerns is the Denneen Motor Co., an organization with $225,000 capital which is building two models of Denmo trucks. The factory occupied is a one-story building with 25,000 ft. of floor space and formerly used as railroad shops. The concern is just starting delivery on its 1¼-ton truck and is bringing out a new 1000-lb. vehicle. Manufacturing plans are to build 1000 of the former and 5000 of the latter. Present capacity is ten trucks per day. The company is under the management of F. S. Denneen, who for 5 years was connected with the engineering department of Chalmers, and later with the Ferro company of this city. Possession was obtained of the present factory 6 months ago, and the development of the present truck has been under way for the past 18 months. A feature of the trucks is that they are sold with complete electrical equipment, including starting and lighting. The storage battery is carried on a spring mounting to overcome truck vibration. The generator is driven at engine speed and is regulated to start battery charging at 5.5 m.p.h. and to be at its maximum charging rate of 12 to 14 amp. at 11 m.p.h.

Standard Welding Plant Doubled

The Standard Welding Co., manufacturer of all kinds of rims for automobile passenger cars and commercial vehicles, has practically doubled its factory during the past year, and has added about $250,000 worth of new machinery. Approximately 85 per cent of this plant has been operating night and day for the last 6 months, prior to which time 75 per cent of the plant was on night shift for several years. To-day 2500 men are employed, and the floor area of the factory is 11 acres. There is capacity for 15,000 rims for passenger cars per day. In addition there is capacity for 1500 bands for truck wheels and 1200 bases for truck wheels per day.

Large Output of Metal Tubing

The entire Standard Welding plant is not given over exclusively to the manufacture of rims, but there is a large production of metal tubing. The factory produces 3,500,000 to 4,000,000 ft. of tubing per month. The company has not experienced any shortage of material, and at present has over $1,000,000 worth of steel stock on hand. It ships fifteen to sixteen carloads of finished product per day, and has three railroad sidings for accommodations for fifty cars.

Next week other Cleveland concerns engaged in the manufacture of motor parts, etc., will be handled.

—

Racing Engine for Ogren Has Integral Oil Leads

LOS ANGELES, CAL., Sept. 22—The Harry A. Miller Mfg. Co., this city, has completed a new racing engine for Hugo W. Ogren of the Ogren Motor Car Co., Chicago, Ill. This engine has recently developed 135 hp. on the block at 2900 r.p.m.

The engine has several unusual features. All oil leads are cast in a crankcase and cylinders, eliminating pipe lines, the water manifold also being cast integral with cylinder head and side plate. The valve action has a follow cam that makes the rocker arm follow the cam. Thus lighter inlet and exhaust springs are used on the valves, as they only have to close the valves and do not have to return the rocker arms. This arrangement enables the motor to attain a speed of 4500 r.p.m.

Four Ball Bearing Crankshaft

The engine has a bore of 3⅝ and stroke of 7 in., and a four ball bearing crankshaft, a double set of ball bearings being used on the flywheel end of the shaft. All valve mechanism is inclosed. Ignition is by two independent Bosch magnetos and a Miller carbureter is employed.

Mr. Ogren intends to place the engine in a chassis of his own design for speedway work.

—

Thirty U. S. Ambulances for Salonica

PARIS, Sept. 22—The American Ambulance Corps has sent to Salonica an ambulance field section with thirty cars provided with full equipment and manned by veterans of the American ambulance service in France.

Battery Care

A MAN looks after his health only after he is sufficiently acquainted with his physical make-up to know exactly what happens when he does not do so. When he is ignorant of what goes on in his body because of certain forms of neglect or abuse, he will generally change his mode of life. The same applies to the property of a man. It is one thing to say vaguely this or that is harmful without stating specifically what harm occurs. It is entirely different to say definitely that a certain kind of neglect will do a clearly defined damage.

The storage battery represents a considerable investment and forms a noteworthy part of the value of the car. Upon its good performance depends most of the comfort of the owner. It is therefore extremely desirable that the owner of the battery should know exactly what he is doing and what harm will result from definite kinds of neglect. He should be taught to know the symptoms of battery illness as he knows the symptoms of his own illness, or of the mechanical ailments of the car.

Concerns have spent hundreds of thousands of dollars merely on educating the public on the storage battery. These instructions have had their effect and the life of the average battery has been lengthened. Nothing is so valuable, however, in carrying the lesson home as to clearly show the exact nature of the damage caused by neglect.

Develop the Tractor

THE short series of articles on tractor engineering concluded in this issue have contained many severe criticisms of conventional practice in the tractor field, but these must not be regarded as destructive criticisms. There is no man of any engineering intelligence who does not know that the tractor of 1925 will be a far more efficient machine than the tractor of to-day. The rapidity of automobile development was due largely to the immense amount of criticism applied to the early machines, both by the public and by the engineers themselves.

The tractor will have no yearly model convention to maintain the pace of progress, so the tractor engineers will have to be even more introspective than their colleagues in the automobile world. The gas tractor is already a wonderfully efficient machine in terms of work done per dollar expended. When its mechanical efficiency is doubled, as it will be easily, its commercial efficiency will be enhanced enough to repay the huge amount of work that has to be done to attain the desired end.

Stop!

THERE is no chain without a weakest link, and there is no automobile without a portion less excellent than the remainder. This must always be so, for it is an attribute of all man-made things, but the weak link ought not too often to be at the same place.

A few years ago the weak spot in nine automobiles out of ten was the electric wiring and connections. It was recognized as a weakness and concentrated engineering work soon removed the troubles and made wiring one of the strongest links.

Now there is no question that the brakes are the weak link in very many cars, and it is equally certain that a little thought and the taking of a little trouble in altering designs would have just as powerful an effect as did similar treatment on the wiring problem. It is manifestly up to the engineering side of the industry to see that the work is done.

Automobile Securities

PERMANENCE and stability as characteristics of the automobile, motor truck and accessory industries are nowhere more strongly in evidence than in the confidence with which the general public invests in their securities. Even before the great bull movement of the past few weeks on the exchanges these stocks were more strongly in demand than those of any other industrial group. The bull activities in steel and copper have perhaps been more prominently featured in the newspapers, but even there the motors, as they are technically termed, are recognized as one of the most important factors in the financial world of the country to-day. The reason for this is that the securities of established automobile companies present substantial investment possibilities, as well as speculative attractiveness due to the phenomenal expansion of the industry.

Star Rubber Co. Is Reorganized

Capital Increased from $200,000 to $400,000—New Stock Is Preferred

AKRON, OHIO, Sept. 22—The Star Rubber Co., this city, has been completely reorganized and its capital stock increased from $200,000 to $400,000. L. H. Firey of Kansas City, a brother-in-law of F. A. Seiberling, president of the Goodyear Tire & Rubber Co., will become president and treasurer of the Star concern. Russell L. Robinson, vice-president of the Robinson Clay Products Co., is the new vice-president, and J. B. Huber, attorney, will serve as secretary temporarily. These officers succeed C. Mulcahy, president; J. W. Miller, vice-president, and W. E. Wright, secretary and treasurer. Fred Gostlin succeeds E. M. Cauldwell, former manager, as superintendent.

The company's original capitalization was all common stock; the new issue of $200,000 is all preferred. It is understood that the old stockholders surrendered their common for equal amounts of the preferred, giving the new management control of the common stock.

The company intends to expand its facilities immediately, starting production with 200 tires a day.

—

Kentucky Wagon Promotes Executives

LOUISVILLE, KY., Sept. 23—W. I. Shaw, who has been sales manager of the Kentucky Wagon Mfg. Co., and the Dixie Motor Car Co., this city, has been made general sales manager of these companies. Stephen K. Miller, who has been assistant sales manager is promoted to sales manager of the wagon department Frank H. Holman has been appointed sales manager of the gasoline truck department and A. B. Challinor will become sales manager of the passenger car department. These promotions and additions have been made necessary by the increase in the company's business. The number of employees is one and a half times the number a year ago.

—

Gemco to Market Products Direct

MILWAUKEE, WIS., Sept. 23—The Gemco Mfg. Co., which heretofore has marketed its products through manufacturers' representatives, hereafter will market direct. Following are the names of those who will represent them in the various centers: Martin E. Dewey, Jr., formerly with the United Engine & Mfg. Co., Hanover, Pa., will look after the trade of New England, Eastern Canada, New York, Pennsylvania and Atlantic Coast, including Florida. Headquarters will be opened in New York. John Craig, formerly of the Benford Mfg. Co., Mt. Vernon, N. Y., will have all of the West, Central West and Southwest to the Rocky Mountains; he will also make the Canadian Northwest. F. W. Jonas will make his headquarters in Los Angeles and cover the territory East to and including El Paso. C. N. Jonas, with headquarters in San Francisco, will look after the Central Pacific section and Rocky Mountain States, including Colorado. R. D. Jonas, with headquarters in Seattle, will cover Washington, Oregon and Vancouver, B. C.

—

5,000,000 Cars in 1919 Is Briscoe's Prediction

JACKSON, MICH., Sept. 22—In a booklet bearing the title "Looking Forward in the Automobile Industry," president Benjamin Briscoe, of the Briscoe Motor Corp. analyzes interestingly the past, present and future of the industry, predicting that by July 1, 1919, there will be 5,000,000 automobiles in use in the United States. Estimating that there are at the present time 2,500,000 cars in use throughout the country and that after deduction of the 1911-made cars which will go out of commission sometime in the course of the present year there will be added to the number now in use about 900,000. Mr. Briscoe thinks that with the start of 1917 there will be 3,300,000 automobiles in operation.

"For the year 1917," writes Mr. Briscoe, "we would deduct the 1912 production of 400,000 and add 1,100,000 which probably will be the production for 1917—production still being influenced by shortage of material and labor—giving us a total at the end of 1917 of 4,000,000 cars in use. At the end of 1918 deduct the production of 1913 of approximately 500,000 and add 1,500,000, making a net increase of 1,000,000 automobiles in use. Estimating these figures as being approximately correct—and they may vary up 500,000 or down 250,000—there will then be operating in the United States a total number of about 5,000,000 automobiles."

—

Toledo-Findlay Tire Directors Elected

FINDLAY, OHIO, Sept. 23—The stockholders of the Toledo-Findlay Tire & Rubber Co., met here recently and elected a new board of directors, as follows: V. T. Spitler, C. I. Moffitt, Frank MacMannes, Charles Rieck, H. O. Fellers and A. O. Hamilton.

The directors abolished the Toledo office and also passed a resolution requesting each member to subscribe for one share of stock. There are 1400 stockholders.

Gramm-Bernstein Co. To Expand

Name Changed to Gramm-Bernstein Motor Truck Co.—Capital $4,000,000

LIMA, OHIO, Sept. 23—The Gramm-Bernstein Co., this city, has been reorganized, its capital stock increased to $4,000,000 and the new company has been incorporated under the name of the Gramm-Bernstein Motor Truck Co. Officers of the new company are: M. Bernstein, president and treasurer; B. A. Gramm, vice-president and general manager; H. O. Bentley, secretary and legal advisor; and R. H. Spear, director of sales. The board of directors consists of Messrs. Bernstein, Gramm and Bentley and two New York bankers whose names will be announced later.

The $4,000,000 stock of the new company is made up of $3,000,000 in common and $1,000,000 in preferred, the par value of all shares being $10. The subscription will be handled by Walston H. Brown & Bro., New York City.

—

Maxwell Ships 550 in Day

DETROIT, MICH., Sept. 23—The Maxwell Motor Co. made a new high record last week when it shipped over 550 cars in one day. This is at the rate of over 160,000 cars per year, although the daily average is at the rate of 120,000 cars annually. The working capital of the Maxwell company is now more than double the plant valuation as given in the report for the year ending July 31.

—

Bradt Is A. B. C. Sales Manager

DETROIT, MICH., Sept. 23—W. J. Bradt, formerly with the Herring Motor Co., Des Moines, Iowa, has been appointed sales manager of the A. B. C. Starter Co., this city.

—

Donahue Is Ross Asst. Sales Mgr.

DETROIT, MICH., Sept. 25—The Ross Automobile Co., has appointed R. W. Donahue assistant sales manager. Mr. Donahue was formerly connected with the E-M-F company, the Oakland Motor Car Co., and more recently with the Liberty Motor Car Co. C. LeRoy Coe, certified public accountant, also has joined the Ross company as its auditor and office manager.

—

Apperson Denies Sales Rumors

INDIANAPOLIS, IND., Sept. 25—Representatives of Apperson Bros., Kokomo, Ind., last week denied rumors to the effect that the company is to be sold to a syndicate.

Kellogg Adds to Factory

Pump Maker Lets Contract for Three-Story Addition—To Enlarge Offices

ROCHESTER, N. Y., Sept. 25—The Kellogg Mfg. Company, this city, maker of Kellogg engine-driven tire pumps, has let contracts for a new three-story building, 100 by 50 ft. The plans also provide for a new heating and power plant, more office room and new offices on the top floor of one of the present buildings. The company's business exceeds that of any previous year by 50 per cent, and contracts with manufacturers now call for more pumps than the company ever produced in one year.

—

Massnick Mfg. Co. Is New Name

DETROIT, MICH., Sept. 25—The Massnick-Phipps Mfg. Co., which makes automobile motors, has changed its name to that of Massnick Mfg. Co.

—

$2 Wheel Tax in Cleveland

CLEVELAND, OHIO, Sept. 23—A wheel tax of $2 a year for all vehicles using Cleveland streets was approved by the City Council Committee on Streets yesterday. An amendment to the traffic rules prohibiting the use of iron tires on motor trucks and requiring rubber tires to be at least ¼ in. thick at the wheel flange was approved.

—

Fostoria Light Car Petitions

TOLEDO, OHIO, Sept. 23—The Fostoria Light Car Co. has filed a voluntary petition in bankruptcy. Liabilities are given as $223,387.42 and assets, consisting of real estate, machinery and materials, at $398,768.44.

—

Campbell Mfg. & Foundry Co. Formed

MUSKEGON, MICH., Sept. 21—The Campbell Mfg. & Foundry Co. has been incorporated, its capital stock being $100,000. The principal stockholders are: H. D. Campbell, J. D. A. Johnson, J. C. Nolen, R. W. Smith, E. G. Filer. The concern has several contracts for forgings and castings for Detroit automobile manufacturers.

—

Studebaker to Enlarge Forge Shop in Detroit 35 per Cent

DETROIT, MICH., Sept. 22—On the announcement last week of the additions to the plants of the Studebaker Corp. to cost $1,500,000, these to be made both here and at the South Bend, Ind., factories, specific information as to just what the Detroit appropriation would be used for was not available.

It is now definitely stated by officials of the big corporation that an increase of 35 per cent in the forge shop capacity here is to be made, as a result of contracts which have just been let for a battery of nine steam hammers, together with all necessary trimming presses, forging and heat-treating furnaces, representing an investment of $150,000. All of this equipment must be installed and in operation by Jan. 1, 1917, according to the contracts.

—

Liberty Appoints Representatives

DETROIT, MICH., Sept. 23—The Liberty Motor Car Co., this city, has appointed R. J. Laciar, Edward Coyle and D. C. Reeves direct sales representatives in the North Atlantic, Central West and Southwest States, respectively. W. J. Davidson, formerly associated with the Cadillac Motor Car Co., this city, has joined the factory sales force of the Liberty concern.

The total value of sales of the new Liberty six, produced by the Liberty Motor Car Co., have passed the $5,000,000 mark. The sales department now is well organized, distributors having been established in most of the principal trade centers.

—

Haynes to Extend Office

KOKOMO, IND., Sept. 25—The Haynes Automobile Co. will build an extension to its present office building 100 by 116 ft. Two lots were purchased last week to make the extension possible. Work will be started at once.

—

Keystone Tire Plant for Pittsburgh

PITTSBURGH, PA., Sept. 23—The Keystone Rubber & Tire Co., Inc., has been formed here to manufacture automobile and motor truck tires. A plant has been secured at Penn Station on the main lines of the Pennsylvania railroad and will be ready for operation within 90 days. The building is a three-story steel and brick structure, 60 by 190 ft., with power house. It will be operated in three 8-hr. shifts, employing about 600 men at full capacity.

Officers of the company are: G. C. Goelitz, president; M. R. Haymaker, vice-president; and R. S. Robb, treasurer. Among the directors are: Cornelius C. Scully of the law firm of Mehard, Scully & Mehard; John D. Graham, recorder of Alleghenw County; Max J. Spann, of the law firm of Dunn & Moorehead and John A. Sharpe, real estate.

—

Silvex Offices to South Bethlehem

NEW YORK CITY, Sept. 23—The Silvex Co. has removed its general offices from 171 Madison Avenue, New York, to South Bethlehem, Pa.

H. & N. Plant in L. I. City

Carbureter Manufacturer Buys New Factory—Will Enlarge N. Y. Service Station

NEW YORK CITY, Sept. 23—The H. & N. Carbureter Co. has purchased a new and completely equipped plant at 138 West Avenue, Long Island City, close to the Queensboro Bridge. The company will maintain and enlarge its service station at 38 West Sixty-second Street, but the main office and retail sales department will remove from 1790 to 1675 Broadway, Oct. 1. The company has branches in Boston, Philadelphia, Los Angeles and Detroit, besides agencies and service stations in the larger cities of the country.

—

Fraud Order Against Piqua Tire

PIQUA, OHIO, Sept. 23—Postmaster General Burleson issued a fraud order against the Piqua Tire & Rubber Co. and M. B. Miller, sales manager, at Piqua, Ohio. The report of the inspector, which was made public with the promulgation of the fraud order, says that Miller advertised in papers, especially those that reach rural communities, that he had automobile tires for sale that were absolutely punctureproof and guaranteed for 6500 miles; that the tires were twice as thick as ordinary makes, and that he would sell them at prices ranging from 10 to 20 per cent less than the cost of standard tires.

The inspector reported that between May 1 and Aug. 19, 1916, the postoffice at Piqua cashed seventy-eight money orders for Miller, which amounted to $1,617.53, and that in none of the cases did he place any orders for tires with the manufacturers.

—

League Agent Pleads Guilty

INDIANAPOLIS, IND., Sept. 23—Harry Van Auken, said to be vice-president of the International Automobile League, of Buffalo, who has been in jail at Uniontown, Pa., since March 8, has entered a plea of guilty and been paroled for 2 years. He was accused by Fayette County officials of conspiring to defraud. The National Vigilance Committee will not prosecute A. C. Bidwell, president of the league, in Uniontown, inasmuch as Bidwell has been forced to pay back all the money taken from Fayette County people, and has paid the expense to which the county and individuals have been put in prosecuting him and his agents. Bidwell, however, will be brought before the federal courts of New York and criminally tried in the near future.

Sparks - Withington Dividend

Directors Declare Initial Payment of 2% on Common and 1¾% on Preferred

JACKSON, MICH., Sept. 22—The Sparks-Withington Co., has declared a dividend of 2 per cent on the common stock. This is for a 6 months' period and places the stock on a 4 per cent annual basis. The dividend is payable Oct. 1, to holders of record Sept. 23.

The regular quarterly dividend on preferred has been declared payable at the same time and to the same record. A quarterly dividend of 1¾ per cent has also been declared on the preferred payable Jan. 1 to holders of record Dec. 15.

There is outstanding $265,000 preferred stock and 768,500 common. The common sold last on the Cleveland exchange at 75. The company was formed in May this year as a consolidation and this is the intial Sparks-Withington common dividend.

—

Wright-Martin Capital $5,000,000

NEW YORK CITY, Sept. 25—Capital of the Wright-Martin Aircraft Corp., comprising the Wright Aeroplane Co., the Glenn H. Martin Aeroplane Co., and the Simplex Automobile Co., will consist of $5,000,000 of preferred stock par $100 and 500,000 shares of common stock without par value. Old stockholders of the Wright Aeroplane Co. can subscribe pro rata to the preferred stock of the new corporation, receiving in addition to each share of preferred bought two shares of the common stock. This privilege expires Oct. 3. It is expected that a public offering of the new stocks will be made shortly.

—

Harroun Treasurer's Office in N. Y.

NEW YORK CITY, Sept. 26—The Harroun Motors Corp. will maintain the treasurer's office in this city. George G. Worthley, former president and treasurer of the Fairbanks Co., having been elected treasurer. F. A. Vollbrecht, former secretary and treasurer of the King Motor Car Co., will handle the factory finances at Detroit.

The Harroun car, which will sell at $595, will have a 3¼ by 5¼-in. four-cylinder block engine, developing 35 hp. at 2800 r.p.m. Valves are carried in a detachable cylinder head, ignition is by Bosch high-tension magneto and the car is designed to make 30 miles per gallon of gasoline. Wheelbase is 107 in. and the tonneau is 40 in. long, the rear seat being 48 in. wide. Tires are 30 by 3½.

—

Dividends Declared

Yale & Towne Mfg. Co. quarterly of 1¾ per cent payable Oct. 2 to stock of record Sept. 26. Also extra dividend of 5 per cent payable Oct. 2 to stock of record Sept. 26.

C. M. Hall Lamp Co., 2 per cent payable to stock of record Sept. 20.

W. K. Prudden Co., 2½ per cent payable Oct. 10 to stock of record Oct. 1.

Stock Prices Soar, Then React

Share in General Upward Movement of Market and Close High

NEW YORK CITY, Sept. 26—The automobile securities have participated in the general upward movement which has characterized the activities of the New York and Detroit stock exchanges during the past week. Many of them have also been affected by the reactions at the beginning of this week, but, on the whole, the tone is considerably stronger than before. Firestone, common, gained 35 points its bid price now being 1050 with the asked at 1080. Goodyear common gained 22, bringing its bid price to 270. General Motors advanced 20 points to a bid of 700 . Saxon was strong, increasing its bid price from 75 to 82. All the Maxwell stocks registered a gain, the common of 4½ points, the first preferred 1⅞ and the second preferred 3 points. Other gains worth mentioning are: Paige-Detroit 2 points; Regal preferred 1 point; Fisk common 3 points; and Reo Motor Car 1 point. United Motors also gained 1¼.

The largest decline was in Packard common, which closed yesterday 14 points below its bid of last Tuesday. Chalmers common lost 13 points and Swinehart Tire 9.

Holders of Willys-Overland common and preferred cannot exercise their rights to subscribe for the new common

Texas Co. Offers New Stock

HOUSTON, TEX., Sept. 22—The Texas Co. directors will ask the stockholders, meeting Nov. 14, to ratify an increase of 25 per cent in the capital, the new stock being offered to old stockholders at par. The increase will make the total capital $55,500,000, the proposed addition being $11,500,000.

—

Materials Market Steady

NEW YORK CITY, Sept. 27—Comparatively few changes took place in the prices of materials used by automobiles, motor truck and accessory manufacturers during the past week. Tin advanced 25 cents per 100 lb. and cottonseed oil went to $10.50 per bbl., an increase of 22 cents. Other changes were: An advance in the price of linseed oil of 3½c., another of ½c. per bbl. in both electrolytic and Lake copper, and decreases of ½c. in antimony and 1½c. in first latex Ceylon rubber.

—

Takes 500 Bour-Davis Cars

DETROIT, MICH., Sept. 25—A contract for 500 Bour-Davis cars for 1917 delivery has been placed by Morton W. Smith of New York, with C. F. Stewart, vice-president and general sales manager of the Bour-Davis company. A large number of additional cars will be taken by Mr. Smith as the company's production increases, and all told the deal involves about $500,000. At the present time Mr. Smith has sales quarters on Fifty-second near Broadway, but contemplates the erection in the automobile district of a ten-story building, to be devoted exclusively to Bour-Davis service and sales.

The Bour-Davis company is now located in its new plant at West Fort and Twenty-third Streets, Detroit, where it occupies a four-story building, 100 by 130 ft. The offices of the company front the second floor, while the remainder of this floor will be used for final testing. The third floor is used for assembling, the fourth for painting and finishing, while the first floor has the stock rooms, wash racks, and stands. The plant has a capacity for thirty cars per day.

Kelsey Wheel to Expand

—

Two Additions, Each 140 by 600 Ft., Will Provide 50% More Space

DETROIT, MICH., Sept. 25—Two additions, both 140 by 600 ft. to the plant of the Kelsey Wheel Co. will be started in a few days and when completed they will provide at least 50 per cent more manufacturing room. The working force, which now totals about 2000 men will be increased to start with by 500 to 600 men and eventually by 1000.

"Our business has never been better," said an official of the Kelsey company to-day. "The general outlook for the automobile business is exceedingly good, and the general increase during the present year is only a forerunner of a much bigger business in 1917."

—

Changes in Capital

LANSING, MICH., Sept. 27—The Atlas Drop Forge Co., this city, has increased its capital from $200,000 to $500,000.

—

Indiana Truck Capital $100,000

MARION, IND., Sept. 23—The Indiana Truck Co., this city, has increased capitalization from $50,000 to $100,000.

—

Akron Rubber Mold Increases Capital

AKRON, OHIO, Sept. 23—The Akron Rubber Mold and Machine Co., has increased its capital from $60,000 to $300,000.

—

American Motors Plant Completed

PLAINFIELD, N. J., Sept. 24—The American Motors Corp., of which Louis Chevrolet is vice-president and chief engineer, has completed its factory. The plant has a capacity of 10,000 cars annually. It has finally decided that the car to be produced will be a five-passenger, six-cylinder model, with 122 in. wheelbase at $1,100. Marcus I. Brock, formerly with the Autocar Co. and with the E. R. Thomas Motor Car Co., has been appointed director of sales. John C. Speirs, formerly with the Autocar Co., the Locomobile Co., Mercer, S. G. V. and Standard Roller Bearings Co., has been made general manager in charge of production.

—

Darling Motor Co. Incorporated

WILMINGTON, DEL., Sept. 23—The Darling Motor Co. has been incorporated here to manufacture automobiles, the capital stock of the company being $300,000. Incorporators are: George W. Dillman; M. M. Dugan, J. D. Frock, all of Wilmington.

—

Dayton Steel Wheel Co. Incorporated

DAYTON, OHIO, Sept. 23—The Dayton Steel Wheel Co. has been formed here with $50,000 capital to manufacture automobile wheels. Incorporators are: George Walther, Jacob Walther, Katie Walther, W. A. Pierce and G. E. Nocholas.

—

36 Entries for Astor Cup Race

Leading Drivers and Fastest Cars to Start in 250-Mile Sheepshead Classic

NEW YORK CITY, Sept. 27—Some very high speeds have been made in practice for the 250-mile Astor Cup Race to be held on the Sheepshead Bay Motor Speedway next Saturday. Louis Chevrolet seems to have his Sunbeam in good shape, as he is credited with two circuits at an average of 114 m.p.h., tying with Christiaens' Sunbeam, which did an equal speed over the four miles. Resta has covered a lap at 109 m.p.h. and Pullen on the Mercer has done five laps at a speed of 104 m.p.h. If the weather is cool and free from wind there is every reason to expect that the record for 250 miles will be lowered Saturday.

Elimination Trials Thursday

When entries closed Monday, thirty-six entries had been received. Since the number of cars which can start in the race is limited to thirty-two, elimination trials will be held on Thursday, Sept. 28 to decide which cars shall participate in the classic. The complete list of entries follows:

Car	Driver	Car	Driver
Crawford	Merz	Maxwell	Rickenb'cher
Crawford	Klein	Premier	Unnamed
Crawford	Chandler	Peugeot	Aitken

Pittsburgh Speedway Buys Land

PITTSBURGH, PA., Sept. 23—The Pittsburgh Speedway Assn. has closed a deal for 600 acres of land and work on the speedway to be constructed here at a cost of $1,000,000 will begin shortly.

The speedway, which will consist of a 2-mile track for automobile and motorcycle racing inside of which will be a track for horse racing, which will be located a short distance southeast of the city.

A. A. A. Contest Board in Session

FRANKLIN, PA., Sept. 23—Richard Kennerdell, chairman of the Contest Board of the American Automobile Assn., entertained the members of the board at his home in this city during the past 3 days. In addition to board meetings, much time was spent at the Wanango Country Club, where golf was the order of the day. Among the board members present were Messrs. Folwell, Ireland, Croselmire, Sinsabaugh, Beecroft and Barnes. John Wetmore and Claire Briggs of New York were among the guests. The board decided to continue the schedule of championship speedway events for next year and, if possible, to increase the number. It is possible that such large speedways as New York, Chicago, Indianapolis, and Cincinnati may have two championship dates and the other speedways one. It is possible that the method of championship awards may be altered in several respects.

Ask New Receiver for Twin City Motor Speedway Assn.

MINNEAPOLIS, MINN., Sept. 27—Attorney D. F. Simpson of Minneapolis, representing bondholders, has asked the district court for a new receiver for the Twin City Motor Speedway Assn. on the ground that the present receiver named by the Ramsey county district court is unable to protect the property properly for lack of funds. The receiver, P. W. Herzog, is believed to oppose foreclosure of the mortgage held by the bondholders and is said to have canceled $100,000 fire insurance because there is no money to pay premiums.

Safety First Federation Appoints Bureau of Standards on Devices

NEW YORK CITY, Sept. 24—The Safety First Federation of America has appointed a bureau of standards, which will investigate the merits of various safety articles or devices submitttd to it. The committees' recommendations will be submitted to the directors for approval and such devices as come up to the standards of the federation will be officially endorsed. Darwin P. Kingsley, president New York Life Insurance Co., is chairman of the bureau and associated with him are Ernest P. Goodrich, E. E. Rittenhouse, Charles Bernheimer, William Guerin, George H. Robertson, Joseph Tracy and William Bondy. Wayne D. Heytecker has been appointed executive secretary of the association, succeeding Frederick H. Elliott, who has resigned.

N. Y. Electric Sociability Run Oct. 4

NEW YORK CITY, Sept. 23—The fourth semi-annual sociability run for electric car owners will be held Wednesday afternoon, Oct. 4, under the auspices of the Electric Vehicle Assn. The run will be from the Electric Garage, Central Park West and Sixty-second Street to Longue Vue Inn, Hastings-on-Hudson, 18 miles, the start being made at 1.45 p. m. The participants will be the guests of the association at tea. Entry cards may be secured from the Electric Garage.

Must Refund Fines in Wisconsin

County Highway Commissioner Cannot Appoint Policemen To Patrol Roads

MILWAUKEE, WIS., Sept. 23—County highway commissioners in Wisconsin have no police power, nor have they authority to appoint policemen to patrol newly improved or any other highways, according to the opinion of the attorney general. Scores of motorists arrested in Brown county in recent months on charges of exceeding the speed limit will receive a refund of fines under the opinion. It appears that Brown county constructed a fine concrete pavement. The county highway commissioner then appointed a motorcycle policeman who used his authority to the utmost. One motorist looked up the law and resisted arrest, and his contention now is upheld by the attorney general.

The State convention of Wisconsin police chiefs, in session at Milwaukee, decided to go before the State Legislature at its next session, beginning in January, 1917, and ask for the passage of a uniform automobile code to apply to all communities and cover all angles. Although there now is a code on the statute books, passed in 1913 and amended in 1915, it has become antiquated because of the rapid development of new conditions affecting the use of motor cars. The chiefs admitted that many unnecessary arrests are caused by conflict in traffic and speed regulations in various communities.

Bosch Closes Eleven Contracts

NEW YORK CITY, Sept. 23—The Bosch Magneto Co. has contracted with the following concerns for the use of Bosch magnetos during the coming season: American Motor Truck Co., Hartford, Conn.; W. H. Gabriel Carriage & Wagon Co., Cleveland, Ohio; Rowe Motor Mfg. Co., East Downingtown, Pa.; Sheffield Car Co., Three Rivers, Mich.; Tiffin Wagon Co., Tiffin, Ohio; Gramm-Bernstein Co., Lima, Ohio; Central American Cars Co., Guatemala, C. A.; H. E. Wilcox Motor Co., Minneapolis, Minn.; Fleetwood Chassis Co., Fleetwood, Pa.; Wolverine Automobile Co., Toledo, Ohio, and Woods Mobilette Mfg. Co., Harvey, Ill.

Hamilton, Ont., Gets Tire Co.

MONTREAL, QUE., Sept. 25—The Richam Mfg. Co. has been incorporated for $150,000 to deal in tires and accessories at Hamilton, Ont.

Pa. Rubber Lowers Prices

Announces Reduction of 10% Effective Oct. 1 on Tires and Tubes

JEANNETTE, PA., Sept. 26—The Pennsylvania Rubber Co., this city, has reduced the prices approximately 10 per cent on its Vacuum Cup, Ebony Tread and Bar Circle tires and Puregum and Paruco tubes effective Oct. 1. These reductions have been made possible, according to the company, by the increase in its volume of production.

The new and old prices on three popular sizes of casings, serving to give an idea of the scale of reduction, are as follows:

Size	Old Price	New Price
VACUUM CUP		
30 x 3	$14.20	$12.40
34 x 4	30.30	27.60
37 x 5	52.75	46.80
EBONY TREAD		
30 x 3	12.05	11.15
34 x 4	25.75	24.85
27 x 5	44.80	42.15
BAR CIRCLE		
30 x 3	10.35	9.70
34 x 4	22.50	21.15
37 x 5	37.05	34.85

Goodrich Adds to Agents

(*Continued from page* 512)

single dealer; still, he would not be given an exclusive territory, the company reserving the right to sell there if it should choose. In fact, one dealer might be placed next door to another.

One tire man states that while the Goodyear company 2 years ago ceased to sell at retail, many of its sales at its branches have been of single tires to small dealers and garagemen who maintain no stock and have no service facilities, they buying one tire at a time as needed.

It is interesting to note that the Goodyear movement is in the opposite direction from the Ford merchandising plan. Whereas Ford extended the number of dealers, Goodyear is decreasing the number.

Buckwalter Is Timken Bearing Engineer

CANTON, OHIO, Sept. 27—T. V. Buckwalter has been appointed chief engineer of the Timken Roller Bearing Co., this city, filling the vacancy caused by the recent resignation of C. E. Vanderbeek. Mr. Buckwalter was formerly connected with the electrical engineering department of the Pennsylvania Railroad at Altoona, Pa., and is the designer of the Buckwalter industrial electric truck.

Briscoe Holds Get-Together Banquet

JACKSON, MICH., Sept. 22—A few days ago the Briscoe Motor Corp. held its first get-together banquet, at which its foremen, sub-foremen, superintendents, department heads, and many other officials were present. The idea originated with H. S. Humphrey, vice-president in charge of manufacture, who explained the reason for the gathering as the need of teamwork to speed up production.

General Manager Frank Briscoe; A. B. Willemin, superintendent of purchases; Chief Inspector K. L. Hermann; K. C. Leverton, factory manager; Dr. DeLong and other officials also spoke.

Court Refuses Standard Roller Bearing Co. Receivers' Petition

PHILADELPHIA, PA., Sept. 27—*Special Telegram*—The United States court here to-day refused the petition of the committee and receivers for the organization of the Standard Roller Bearing Co. and for the transfer of the license which was granted by the Hess-Bright Corp., holder of the Conrad patents on ball bearings, which is about to expire. Judge Thompson's decision supports the opposition of the stockholders' protective committee that the legality and the interpretation of the contract are involved.

Bache, of Bound Brook Bearing, Dies

BOUND BROOK, N. J., Sept. 24—Leigh Stanley Bache, for the last 5 years first vice-president and general manager of the Bound Brook Oilless Bearing Co., died here Sept. 21. He was born Sept. 18, 1870. Mr. Bache had been continuously connected with the Bound Brook company since 1899.

1000 Cars in Highway Demonstration

CHICAGO, ILL., Sept. 26—Approximately 1000 cars took part in a tour of protest along Sheridan Road, the main highway between this city and Milwaukee, the object being to compel improvement of this route which is in a very bad condition. The tour was arranged by the Sheridan Road Improvement Assn. and was run in two parts, one headed by Gov. Dunne of Illinois.

Aitken Used Goodrich Silvertown Cords

NEW YORK CITY, Sept. 27—In the report of the recent Indianapolis race the tire equipment of the winning Peugeot, driven by John Aitken, should have been given as Goodrich Silvertown cords. The tabulation of equipment published in THE AUTOMOBILE gave the tires of this car as of another make.

More Capital for Kelly Truck

Special Stockholders' Meeting Oct. 10 To Increase Common To $2,000,000

SPRINGFIELD, OHIO, Sept. 27.—A special meeting of the stockholders of the Kelly-Springfield Motor Truck Co., this city, will be held Oct. 10 to increase the common stock of the company to $2,000,000. Preparatory to this step the company has decreased its capital from $2,500,000 to $1,914,000 in accordance with the requirement of the law of Ohio that a company cannot increase its stock unless all its original capital stock has been subscribed. The increase is to provide for the rapidly expanding business of the company.

The preferred stock of the Kelly-Springfield company is $1,014,000, the outstanding common since the reduction being $900,000. The common was originally $1,000,000.

A few days after the stockholders' meeting the directors of the company will meet to determine the amount, if any, of the new common stock to be issued.

$100,000,000 G. M. C. Corp.

(*Continued from page* 511)

New York, the plan of the readjustment was formally approved. The new company, which will be a Delaware corporation, will absorb the old, and will consist of 1,000,000 shares of the par value of $100. Of these, 200,000 will be 6 per cent cumulative non-voting preferred stock, redeemable on and after Sept. 1, 1918, at the option of the company, at $110, plus accrued dividends. The basis of exchange follows:

(a) For each share of present preferred stock, one and one-third shares of the new preferred stock.

(b) For each share of present common stock, five shares of the new common stock.

Stock to be exchanged may be deposited with the Guaranty Trust Co., New York on and after Oct. 18, and not later than Dec. 15, 1916.

The annual statement of the General Motors Co. is the most favorable that the company has ever made. The net profits are practically double what they were

GENERAL MOTORS SUBSIDIARY COMPANIES

Company	Stock Outstanding	Owned by General Motors
Buick Motor Co., preferred	$500,000	$500,000
Buick Motor Co., common	2,000,000	2,000,000
Cadillac Motor Car Co., common	1,500,000	1,500,000
Oakland Motor Car Co., common	800,000	800,000
Olds Motor Works, common	3,132,390	3,132,390
Northway M. Manufacturing, common	725,000	725,000
Champion Ignition Co., common	100,000	75,000
Jackson, Church, Wilcox, common	240,000	240,000
McLaughlin Motor Car Co., common	1,003,000	500,000
Weston-Mott Co., common	1,500,000	1,500,000
General Motors Truck, common	250,000	250,000

last year. Out of the surplus the company was able to pay off $2,328,000 notes; $1,048,964 preferred dividend; $10,730,150 common dividend; $3,726,752 for plant additions. This makes a total deduction of $17,833,875, and the cash was increased $7,950,451.

Under the head of Operating Expenses full charges have been deducted to cover all depreciation in inventory which at the close of the year were in a conservative basis of valuation. The increase of $11,051,051 in the value of inventories is due to increased volume of business. The company has no funded debt, the $2,328,000 first lien 6 per cent notes having been paid at maturity when the voting trust was dissolved Oct. 1, 1915.

The total indebtedness of the company and its subsidiaries consisted of $7,264,443, which was for current accounts payable, mostly for merchandise, and $2,690,832. Liabilities accrued but not due were payrolls, taxes, etc.

The company has at present in the hands of the public $14,985,200 in 7 per cent cumulative preferred stock and $16,511,783 in common stock. This represents an increase in the common stock of $5,000 during the year.

The gross sales of the company amounted to $156,900,296 as compared with $94,424,841 for 1915, a gain of $62,475,455. The number of cars sold was 132,088 as compared with 76,068 during the previous year, an increase of 56,020.

First Common Dividend 50 per Cent

The common stock paid its first cash dividend Oct. 15, 1915, when 50 per cent, or $50 per share, was paid to stockholders. Subsequently quarterly dividends of 5 per cent have been paid up to date. The rate of dividends follows:

	1909	1910-11	1912	1913-14	1915	1916
Preferred	7	7	7 7/12	7	7	7
Common	150*	..	....	..	50	20

*Paid in common stock.

The General Motors Co. was incorporated under New Jersey laws on Sept. 16, 1908, under a perpetual charter. The purpose given in the charter was to manufacture and deal in motors, automobiles and machines and to acquire from other businesses of the same general character. At the present time the General Motors Co. is composed of ten subsidiary companies, as shown in the tabulation on page 551.

Most of these subsidiary companies produce complete automobiles and the others produce the various units, such as motors, ignition specialties, steering gears, gearsets, rear axles, etc.

The estimated present capacity of the various General Motors car-producing subsidiaries is 139,000 cars per year. At the present time General Motors companies operate factories having an aggregate of 5,711,000 sq. ft.

W. C. Durant is president of the General Motors Co., the other officers being as follows: Vice-president, A. G. Bishop; secretary, Standish Backus; treasurer, James T. Shaw; and comptroller, W. H. Alford. Pierre S. DuPont is chairman of the board of directors, other directors being F. L. Belin, H. E. Bishop, W. P. Chrysler, R. H. Collins, W. L. Day, W. C. Durant, J. A. Haskell, L. G. Kaufman, W. C. Leland, J. H. McClement, C. S. Mott, J. J. Raskob, C. H. Savin, F. W. Warner, A. H. Wiggin.

Commerce Truck Expands

Increases Capital To $400,000—To Build 3000 of New 1-Ton Trucks

DETROIT, MICH., Sept. 27—The Commerce Motor Car Co. has increased its capital stock from $200,000 to $400,000. Of this, $100,000 is subscribed for by present stockholders. The company is bringing out a new 1-ton truck, of which 3000 are to be built during the fiscal year. The price is $1,175 for the chassis with seat. There will also be made 1800 ¾-ton trucks. An addition 250 by 60 ft. is being added to the plant.

Factory Miscellany

Apperson Moving—The most recent addition to the Apperson plant, Kokomo, Ind., is completed and the machine shop is being moved over from the old building. The addition of more than 90,000 sq. ft. has been made by the building of the new plant which is known as plant No. 2. It is an entirely modern structure and houses several departments as well as the machine shop. It also embodies a large shipping platform.

Hudford Takes Larger Plant—The Hudford Co., Philadelphia, Pa., maker of the Hudford attachment for converting Ford cars into trucks, has moved into a building at Sixteenth Street and Glenwood Avenue in order to permit an increase in production.

Moline Plow Adds—The Moline (Ill.) Plow Co. will complete a new addition to the plant about Nov. 1 which will give employment to 600 men. The addition will be devoted exclusively to the manufacture of farm tractors. The principal building now under construction will be 100 feet by 785 feet. Another building 180 by 360 will be used as a foundry and for housing the metal parts. The company is far behind in its orders for tractors, and the expansion is imperative.

Indianapolis Firm Increasing—The Metal Auto Parts Co., Indianapolis, has bought 4 acres of land in West Indianapolis and will build four additions to its plant. Production will be more than doubled.

Overland in Green Bay—The Overland-Green Bay Co., Green Bay, Wis., has awarded contracts for the erection of a $40,000 branch house, service station and repair shop, 100 by 122 ft., at Pearl and West Walnut Streets. It will be of reinforced concrete, two stories and basement and will be used for the distribution of Overland cars in northeastern Wisconsin.

Specialize on Hearses—The Houghton Motor Co., Marion, Ohio, announces its production scheduled for the coming year as 500 ambulances and hearses. Fifty of the vehicles are to be delivered by Jan. 1, 1917. All vehicles are to be delivered by Oct. 1, 1917. The concern has been devoting the past year to experimental work.

Heider Tractor Builds—Work commenced this week upon the new building of the Rock Island (Ill.) Plow Co., to be used as an assembling plant for the Heider tractor. Parts for the tractor are manufactured in the general plant of the plow company, and will be put together in the new structure, which will cover a city block, eight houses being removed to make room for the addition. Only steel and concrete will be used in the construction. Last December the Rock Island Plow Co. acquired control of the Heider tractor, then in operation at Carroll, Iowa, and the equipment of the latter plant was removed to Rock Island.

Goodyear to Have 20,000 Men—Twelve hundred and fifty men are engaged in erecting new buildings for the Goodyear Tire & Rubber Co. at Akron, according to H. S. Quine, secretary to President Seiberling. Goodyear building operations now include more room for the office force as well as factory space. The company expects to be employing 20,000 men within a year.

Goodyear's New Cooling Tanks—To provide for the constant flow of electric power and at the same time conserve the water supply which rotates the great 10,000-K.V.A. turbine at the plant of the Goodyear Tire & Rubber Co., Akron, Ohio, the company is erecting a battery of five cooling towers, the first to be installed by any of the large rubber companies of the country. The cooling battery is being installed in five sections, each equipped with a 12-ft. rotary fan. In Europe, cooling systems of this type have been in use for some years.

To Make Motors—The Carle Motor Parts Co., Buffalo, N. Y., has filed incorporation papers to manufacture motors for automobiles and commercial vehicles. Harold Carle, 652 Humboldt Parkway, A. L. Dixon and J. F. Meha, all of Buffalo, are the incorporators.

Complete Michigan Stamping Plant—Work is progressing rapidly on the new plant of the Michigan Stamping Co., Mack Avenue, Detroit, Mich., and by Oct. 1 it is expected that the building will be ready for occupancy. It is rectangular in shape, 370 ft. wide, 650 ft. long. Over 1000 men will be employed and this force will eventually be doubled. The total expenditure will be approximately $1,000,000 for buildings, general equipment and new machinery. Automobile frames, gasoline tanks and many other car parts are made by the company.

TRACTOR

Oct. 14-29—Dallas, Tex., Demonstration, Texas State Fair.

The Week in the Industry

Williams Gets Liberty Agency—C. R. Williams will handle the Northwest agency for the Liberty six, at Twelfth Avenue and Pine Street, Seattle, Wash.

Capen Goes to Chicago—Wallace C. Capen, St. Louis, will become manager of the Chicago branch of the White company. He will take with him C. F. Feltz, manager of the service department in St. Louis.

Handles Cadillac in Delaware—For the purpose of handling the Cadillac in Delaware, the Delaware Motor Sales Co., Wilmington, Del., has been formed. It has taken over the business of the Harris Engine Co. in the State.

Celebrate New Building—For 3 days recently the Connell & McKone Co., Boston, Mass., agents for the Overland, had open house in their new building. More than 1500 people visited the salesrooms during the 3 days. More than twenty-five orders for new cars, twenty used cars and ten trucks were booked.

Ohio News Notes—The Winders Motor Sales Company, central Ohio distributer for the Chevrolet, has moved into a new and larger building at 182-184 East Long Street, Columbus, Ohio.

The Logan Garage & Machine Co., Toledo, Ohio, has again enlarged its quarters. The present location of the concern is 329-331 Broadway.

Pathfinder in Philadelphia—The Hetherington Motor Company, of Philadelphia, has been organized and will handle the Pathfinder. The incorporators are Albert G. and S. C. Hetherington, the latter formerly head of the Crow-Elkhart Sales Company, which will be absorbed by the new company. The company is located at 5 North Twenty-first Street.

Spalding Missouri Packard Vice-President—H. W. Spalding, St. Louis, general manager of the Packard Missouri Motor Car Co., has been elected vice-president of the company and placed in charge of the sales department. He is succeeded as general manager by Gilbert S. Loomis, who has been in charge of the Packard interests at Louisville, Ky.

St. Louis News—W. E. Finney, St. Louis, recently manager of the Goodyear Tire & Rubber Co. branch in that city, has been assigned to the mechanical goods department at the Goodyear factory at Akron, Ohio.

O. E. Hoerger, St. Louis, recently assistant to Wilson C. Dodd, manager of the Goodyear branch, has been promoted to operating manager of the Goodyear branch in Boston.

Nebraska Trade Items—J. Roy Smith, Tecumseh, Neb., and Guy L. Mastin, Auburn, Neb., have formed a partnership with headquarters at Tecumseh, to handle the Oldsmobile in nine Nebraska counties.

Oscar Weibel, Dewitt, Neb., has sold his garage to C. M. Messmore, Nebraska City, Neb.

Jay Wiggins, Lincoln, Neb., has disposed of his garage to Frank Harding.

Hamilton & Cornish, Craig, Neb., have procured the Bovee Garage from Tamisiea & Morehouse.

John P. Michelson, Nebraska City, Neb., has bought the garage of John DeFord.

Iowa Trade Notes—Charles Coons, Carson, Iowa, has bought out his partner, Orville Henry, and will conduct the business of the Main Garage alone.

Chris Bunderson, Harlan, Iowa, has bought the interest of Fred Mortensen in the Court Street Garage.

Barney Boysen, Schleswig, Iowa, has bought out his partner, Charles Reinking, in the Boysen & Reinking garage.

H. H. Dufty and J. H. Blackmore, Tingley, Iowa, have bought the Tingley Garage from Jonas Fender.

J. A. Weber, Stacyville, Iowa, has bought the Stacyville Garage from R. I. Galloway.

Peter Mathre, Ames, Iowa, has purchased the Lou Robertson auto repair shop and opened for business.

Jack Chauncey, Ute, Iowa, has opened a new garage.

Nebraska Items—Northrup & Bolton, Omaha, Neb., are installing a service station for Chandler owners. The firm recently took over the line, which was formerly handled by the W. L. Huffman Automobile Co.

The L. F. Strubbe Auto Co., Omaha, Neb., has been organized by L. F. Strubbe and C. D. Bothwell, experienced automobile men of Lincoln and Omaha, respectively. They have opened at 2415 Farnam Street and will handle the Ross Eight.

W. M. Clement, Omaha, Neb., for several years treasurer for the W. L. Huffman Automobile Co., has launched into business for himself at 2006 Farnam Street. He will handle the Scripps-Booth.

William H. Gestring, Benson, Neb., has opened a Ford service station on Military Avenue.

New England Trade Items—Hon. Taber D. Bailey, one of the proprietors of the Bangor Motor Company, at Bangor, Me., has sold his interest to Horace W. Chapman, son of a partner in the company.

The Reliable Tire & Rubber Co., at Boston, Mass., has been reorganized and its name changed to the Inter State Rubber Company. It has moved into new salesrooms, 392-394 Newbury Street.

M. D. Kidder, Eastern sales manager for the Reo Motor Car Company for five years, and until recently wholesale manager for New England, has taken over the Maine agency at Portland.

Arthur S. Lee has formed the Union Motor Car Company at Providence, R. I., to handle the Mercer and Stearns Knight, with salesrooms on Broad Street. He was formerly secretary of the Rhode Island Automobile Dealers' Association, and handled the Stevens-Duryea there for years.

Horace S. Putney has joined the Oldsmobile agency at Manchester, N. H., as sales manager. He was formerly with the Noyes Buick Company.

The United States Light and Heat Corporation, Buffalo, N. Y., has closed up its Boston, Mass., branch and turned the business over to the Boice-Perrine Company as an agency proposition.

H. C. Darling has been appointed manager of the Western Massachusetts Longford Company, succeeding E. E. Hildreth.

South Bend Activities—The Monroe Motor Car Co. will open a salesroom in a short time which will be a branch of the Monroe Motor Car Co., Pontiac, Mich. The Kirby brothers will have charge of the place. L. J. Stevenson, a factory representative, will be in South Bend to assist in the opening. The salesroom is expected to be one of the most attractive in this section.

The Studebaker Corp. will erect a large service garage in South Bend which will handle the product of the concern's factories, according to plans now being considered. The structure will be approximately 100 by 165 ft. No idea of the cost of the garage has so far been given out. Plans and specifications will be prepared soon. Mr. Fish, chairman of the board, said: "We contemplate building a garage and will begin construction as soon as we have obtained our plans and specifications so that the contracts may be let.

King Dealers Move—The New Ogden King Eight Co. have found it necessary to find larger quarters for their showroom and have moved to 2564 Washington Avenue, Ogden, Utah.

Stewart V-Ray Spark Plug

Like a Bolt From the Blue

No sooner had we announced the fact that we were making and marketing the famous V-Ray plug than an avalanche of inquiries and orders began pouring in from dealers in all parts of the country.

Such enthusiasm simply swept us off our feet.

It was like a bolt from the blue.

Dealers know V-Ray quality and realize the bigness of the V-Ray market.

They know that all that held back V-Ray sales in the past was limited production facilities.

That handicap has been removed.

And V-Ray production is keeping up with the V-Ray demand—a demand that is on a rapid increase.

Write or wire in today for prices and full information.

"It will pay you to see that the car you own is equipped with Stewart Products"

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, OCTOBER 5, 1916—CHICAGO NO. 14

Fisk Capital Now $39,500,000

Stockholders Vote To Add $24,500,000 in Preferred and Common

CHICOPEE FALLS, MASS., Oct. 2—At a special meeting of the stockholders of the Fisk Rubber Co. here to-day it was voted to authorize an increase in the capital stock of the corporation from $15,000,000 to $39,500,000, adding $24,500,000, divided as follows: $7,500,000 first preferred convertible stock of which $5,000,000 will be issued at once; $5,000,000 second preferred of which $2,500,000 will be issued and $12,000,000 common stock which will remain in the treasury.

The additional issue of second preferred is being taken by the junior security holders, being offered to them on a basis of one share for every four shares of common and second preferred owned in the aggregate. The first preferred has been underwritten by a syndicate headed by Estabrook and Co. of Boston. The new cash is to be used for working capital.

Offer $1,500,000 Winton Preferred

CLEVELAND, OHIO, Oct. 4—Borton & Borton have purchased and will offer shortly to the public, $1,500,000 7 per cent cumulative preferred stock of the Winton Co.

Although the Winton Co. is not disposed to change its policy of limited production, the company will devote the proceeds of this issue to expansion of the plant.

The company's balance sheet will show total assets of approximately $300 for each share of preferred stock to be issued. Average earnings over the last 7 years have been at the rate of about four and a half times the preferred stock dividend requirements.

The company agrees to maintain net quick assets of 125 per cent of preferred stock issue. A sinking fund will be operative beginning 1919, which will retire the issue at the rate of $75,000 annually. It will be redeemable at 105 and accrued dividends.

U. S. May Develop Gasoline Standard

WASHINGTON, D. C., Oct. 1—The price of gasoline may be regulated by the Federal Government as the result of an investigation now being conducted by the Department of Commerce which is trying to determine what is gasoline and what is not. It is hoped to arrive at a basis for fixing a standard for gasoline.

—

Young Is Dort Experimental Engineer

DETROIT, MICH., Oct. 3—M. S. Young has resigned his position as chief engineer of the Regal Motor Car Co. to accept the position of experimental engineer for the Dort Motor Car Co., Flint, Mich.

Paige 1916 Gain $1,000,000

$1,058,300 Cash on Hand—Net Worth $1,994,644—Surplus $994,644

DETROIT, MICH., Oct. 2—The Paige-Detroit Motor Car Co., this city, showed a net gain of $1,072,152.35 for the year ending Aug. 31, 1916. The net worth of the company at the end of August, 1916, was $1,994,644.79 and at the end of the same month in 1915 was $922,492.44.

The company in its financial statement shows cash on hand and in banks amounting to $1,058,300.66. Its surplus amounted to $994,644.79 and its capital stock to $1,000,000.

Paige Financial Statement Ending Aug. 31, 1916

Hatch Perfection Spring Sales Manager

CLEVELAND, OHIO, Oct. 3—After 9 years of successful work in the sales department of the Perfection Spring Co., C. W. Hatch has been appointed sales manager.

21,660 Carloads in September

Gain of 2720 Over Shipments in 1915—Freight Car Shortage 14,000

CARLOAD SHIPMENTS OF AUTOMOBILES

Month	1916	1915
January	18,054	8,369
February	21,502	11,273
March	28,600	16,442
April	28,000	17,112
May	24,000	13,642
June	23,879	15,325
July	18,079	12,517
August	18,254	16,959
September	21,660	18,940

NEW YORK CITY, Oct. 4—At the regular meeting of the board of directors of the National Automobile Chamber of Commerce, Inc., held here to-day the traffic committee reported that shipments of automobiles and trucks during the month of September totaled 21,660 carloads, as compared with 18,940 in September, 1915, a gain of 2720 carloads.

The American Railway Assn. reported to the chamber that there is a shortage of 14,000 freight cars and automobile manufacturers are making strenuous efforts to induce their dealers to empty their cars promptly so that they can be put into use again with minimum delay.

The patents, good roads, legislative, safety first and show committees reported and their reports were accepted.

Show Space Drawings

The directors' meeting to-day was preliminary to the meeting to-morrow when drawings for space at the national shows will be held.

Smith Form-A-Truck Takes License Under Cook Patent

NEW YORK CITY, Oct. 4—The Smith Form-A-Truck Co., Chicago, has taken out a license from the Redden Motor Truck Co., this city, to manufacture converted trucks from touring cars, under the Cook patent, controlled by the Redden company. The Smith company has up to the present converted Ford touring cars into delivery vehicles, having as its patent in this work No. 1,147,131, granted to W. P. Wynne, July 20, 1915, and applied for June 29, 1914. The Redden company controls patent No. 1,180,475 granted to A. E. Cook and T. Van Tuyl, April 25, 1916. It was applied for under date of Dec. 17, 1910.

The Smith-Form-A-Truck Co. will continue manufacture of apparatus for converting Ford touring cars into delivery wagons as heretofore, but will do so by payment of royalty on the Cook patent. The contract between the Redden and Smith firms is apparently based on the validity of this patent. The Smith Form-A-Truck Co. is one of the largest manufacturers of these truck-making attachments. It was in 1914, when A. D. Smith built his first truck attachment in Seattle, Wash. In May, 1915, the first one for the Chicago trade was manufactured. In August, 1915, the Smith-Form-A-Truck Co. established a Chicago plant and started the manufacture of these attachments on a large scale.

The scope of the Cook patent is well defined in some of the patent claims, No. 32 of which reads:

"The combination with an automobile of a pair of tractor wheels, a frame supported thereon and affording means to elevate the rear end of the automobile thereon, means on said frame for rigidly engaging the rear end of the automobile thereon, means supporting the front end of the frame on and securing the same to the front end of the automobile, and driving connections between the tractor wheels and the power plant of the automobile."

Madison Motors Co. Absorbs Old Company

ANDERSON, IND., Oct. 1—The Madison Motors Co., with a capital of $2,000,000, has been organized here to absorb the Madison Motor Co., formed in the spring of 1915 with a capital of $500,000 to manufacture the Dolly Madison car. The new corporation will take over the local plants of the old company and will continue the present models on a larger scale of production.

Cecil Gibson, president of the old company, remains at the head of the new one. The board of directors will include C. D. Edinburg, general manager of the American Maize Products Co., New York City; W. F. Wickham, president of the Wickham Coal Co., St. Louis, Mo., and of the Wickham & Burton Coal Co., Chicago; P. P. Haynes, an attorney in Anderson; G. S. Sarber, formerly of Indianapolis and associated with Mr. Gibson in all his enterprises; and H. M. Caldwell, Evanston, Ill., capitalist and corporation attorney, who, it is said, is largely responsible for the new capital which goes into the company.

—

Perrin Resigns from Timken Axle

DETROIT, MICH., Oct. 1—J. G. Perrin resigned to-day from the Timken-Detroit Axle Co. because of serious illness and other business plans.

—

Automobile Crank Shaft Corp. Formed

DETROIT, MICH., Oct. 4—The Auto Crank Shaft Co. has sold its entire business and assets to the Automobile Crank Shaft Corp., recently incorporated under the laws of New York with a capital of $1,000,000.

There will be no change in the officials of the company.

Columbia Motors Buys Argo

New Company Capitalized at $500,000—To Make 3500 Electrics in 1917

DETROIT, MICH., Oct. 2—The Argo Electric Vehicle Co., Saginaw, Mich., has been purchased by the Columbia Motors Co., this city. The Columbia Motors plans to begin the manufacture of its new car Jan. 1, 1917. This company is capitalized for $500,000 and expects to produce approximately 3500 cars during the coming year at a price of about $1,000. The first Columbia was produced early this summer, but further production was delayed pending the Argo purchase.

The new merger admits the Columbia Motors to a membership in the National Automobile Chamber of Commerce, and allows them to exhibit their product in the national automobile shows in New York and Chicago this next winter.

The officers of the Columbia Motors Co. include: J. G. Bayerline, president and general manager; A. T. O'Connor, secretary and treasurer; T. A. Bollinger, vice-president in charge of manufacturing; Walter L. Daly, sales manager; Ray Long, chief engineer; W. E. Metzger, vice-president, and John Mohrhardt, superintendent. All are members of the board of directors.

—

Standard Welding Makes Promotions

DETROIT, MICH., Oct. 4—Following the resignation of H. A. Flagg, sales manager of the Standard Welding Co., and C. E. Miller from the management of the Detroit office of the same company. P. W. Gilbert, assistant sales manager for nearly 5 years, becomes sales manager; B. A. Quayle, in charge of the Chicago office for many years, and one of the company's first salesmen becomes general representative, with headquarters at the factory. B. G. L. Dodge, in charge of advertising and publicity for over 5 years, becomes manager of sales promotion.

W. C. Voss, formerly in charge of the Cleveland district, moves to Detroit, where he will assume charge jointly with Ted Palmer, long connected with the Michigan office. Willis Stutson, of the Indianapolis district, is placed in charge of the Chicago office with A. J. Brandt as assistant. Mr. Stutson will also handle the Indianapolis district from Chicago. O. L. Miller, formerly of the order department at the factory, replaces Mr. Voss at Cleveland. T. E. Hauser, formerly head of the order department, becomes assistant to the sales manager, while W. Paxton becomes head of the order department.

26,304 Reo Production in Year

23,753 Cars and 2551 Trucks—Gross Sales Total $27,884,000

LANSING, MICH., Sept. 29—During its 1916 fiscal year the Reo Motor Car Co. delivered 23,753 passenger cars and the Reo Motor Truck Co. 2551 trucks. All told, 26,304 Reos were delivered to purchasers. The gross sales during the year totaled approximately $24,363,000 for the car company and $3,521,000 for the truck company, or a total of $27,884,000 for all Reo sales. In the case of the passenger-car company the increase over the fiscal year 1915 is 33.08 per cent and the increase for the truck concern is 33.38 per cent, or an average increase of 33.24 per cent for all Reo business.

These are some of the facts which were brought out in the report submitted to stockholders who met this week with regard to the merger of the two Reo companies, which is now an accomplished fact. In the report it was further stated that at the close of the fiscal year 1915 the Reo Motor Truck Co. had capital stock issued and outstanding of $937,250 and about $250,000 surplus. The net earnings of the year were $502,000. The Reo Motor Car Co. at that time had $3,000,000 capital stock outstanding and $3,662,000 surplus. Upon the present capitalization of $6,000,000 the surplus would have been $662,000 and the net earnings for the 10 months ended then were $2,569,000. This, prorated by months, would show an earning of around $3,000,000 for 12 months. Both corporations were earning at the rate of approximately 50 per cent of their present capital.

As a result of the merger it was decided that the stock will be exchanged on a share-for-share basis, the holders of truck stock receiving 93,725 shares.

After having been delayed because building material was slow in being received, the Reo Motor Car Co., now having received a large supply, is rushing the completion of its new large machine shops. Part of the structures are three stories high, 407 ft. long by 175 ft.

Plans Clearing House

The Reo company is planning to establish a clearing-house division in its welfare department for the benefit of its employees. The object of the clearing house will be to help Reo employees having real estate or personal property in selling or buying and otherwise taking care of their property, and it will also do away with intermediaries.

To Export 2000 Harroun Cars Per Annum

NEW YORK, Sept. 28—A contract involving the exporting of 2000 Harroun cars per annum for 5 years and a total of $5,000,000 was entered into to-day between the Harroun Motors Corp. and Speyer, Cole & Company in association with Graham & Co. of London, and Norton Lilly & Co. of New York is announced by John Guy Monihan, president Harroun Motors Corp.

The contract provides for the exclusive dealing in Harroun cars in England and the colonies except Canada. For 8 years these gentlemen have been the export dealers and managers for the Hupmobile company, which they continue to handle with the Harroun.

Tompkins in Ward Leonard Organization

MOUNT VERNON, N. Y., Oct. 2—William Miller Tompkins has been made Philadelphia representative of the Ward Leonard Electric Co., Mount Vernon, N. Y.

Aug. Exports Total $10,068,538

5254 Cars Valued at $3,574,485 and 1565 Trucks at $4,442,158

WASHINGTON, D. C., Oct. 2—Figures made public to-day by the Department of Commerce show that 6819 automobiles, valued at $8,016,643, were exported in August last, as against 5453 cars, valued at $7,509,027, shipped abroad during the same month of last year. The August exports this year were divided as follows: commercial cars, 1565, valued at $4,442,158; passenger cars, 5254, valued at $3,574,485; parts, not including engines and tires, $2,051,895. During August of last year there were 1614 commercial cars, valued at $4,387,193; and 3839 passenger cars, valued at $3,121,834, exported, together with parts, not including engines and tires, to the value of $2,038,321.

The big feature of the exports for the 8 months ended August, 1916, was the number of passenger cars exported, the number being 43,661, valued at $29,472,228, as against 26,736 cars, valued at $23,576,188, exported during the corresponding period of 1915. On the other hand, the exports of commercial cars dropped from 15,042, valued at $41,886,961, during the 8 months of 1915 to 12,938 cars, valued at $35,167,840, during the same period of this year. Exports of parts, not including engines and tires, increased from $9,381,440 during the 8 months of last year, to $15,227,161 during the same period of this year.

The large gain in our automobile export trade in recent years is indicated by the figures for the 8 months of 1914, during which time 509 commercial cars,

BRAZIL

Imports of U.S.A. Cars into Brazil are Increasing But Should Grow Faster—Sao Paulo One of Most Promising Centers for Cars and Trucks

Part II

By David Beecroft

EDITOR'S NOTE:—This is the second of a series of articles embodying the close observations of automobile and general trade conditions in Brazil made by Mr. Beecroft, Directing Editor of THE AUTOMOBILE, during a 10-weeks' trip through Argentina, Uruguay and Southern Brazil as a delegate of the United States Government and member of the Argentine Return Visit Committee. Subsequent articles will further analyze the possibilities of selling cars, trucks, and tractors in the United States of Brazil.

Diagram showing the comparative areas of Brazil and the U. S. A.

THE area of the United States of Brazil as compared with that of the United States of America is brought out in the above map, in which Brazil has been placed over the U. S. A. Both, as stated last week, approximate the 3,000,000-square-mile area, but with vastly varying populations, Brazil with 25,000,000 and U. S. A. with 105,000,000. On an average the potential buying ability of the U. S. A. per 1000 of population is much higher than Brazil.

During the last 7 years Brazil, according to the figures of her own government, has imported 10,523 automobiles and trucks. This is an average of 1503 per year. The importation of automobiles into Brazil has been very irregular, there has not been any general trend of movement. There has been a pronounced anti-climax. Two years stand out conspicuously as strong years for Brazilian imports—1912 and 1913. The high water mark of imports was in 1912 when the total of 3785 was reached. The U. S. A. received about 20 per cent of that business. Germany got nearly 40 per cent.

The following year, 1913, was a strong year with 3218 cars imported, a little lower than the previous year, but still a fairly successful one. In that year we passed Germany, but remained behind France, which had been passed by Germany the year previous.

It was in 1914 that the bottom literally fell out of the Brazilian market and it has been out ever since, except for the developing business in the State of Sao Paulo. In 1914 importations dropped to 744 cars, scarcely one-fifth of what it had been the previous year.

1915 the Worst Year

But if 1914 was a solar plexus blow the figures of 1915 showed a still worse condition. The imports fell from 744 to the low level of 214. European business stopped, excepting fifteen cars from Italy, eight from Great Britain, ten from France and three from Switzerland. The U. S. A. got the lion's share, 169 cars out of 214, but even then our business declined as compared with the previous year.

In the last fiscal year ending June 30 our exports had risen to 258 cars, a good increase over the previous year, but still a small quantity as compared with 4444 cars sold to Argentina in the same period. The tabulation on the opposite page shows year by year an analysis of Brazilian imports from different countries.

These figures give some indication of the strength of both France and Germany in the Brazilian field, and account for the preponderance of French and German cars, not only in the capital, but in other leading Brazilian cities. The highest-priced French and German cars were sold in many of the leading cities such as Rio de Janeiro, Sao Paula, Santos, Porto Allegre, Manaos, Bahia, Pernambuco and Para. Great Britain was never a contender for the Brazilian trade in the sense of France or Germany. Italy was a much greater factor than Great Britain. Belgium and Switzerland were also striving for a slice of the Brazilian trade.

The distribution of cars throughout Brazil has been much more general than is supposed. Rio has been the big consuming center, but several other places were growing as car-consuming centers when they were overtaken by the war in 1914. That stopped their importing activities. The tabulations showing how many cars were received at the different ports of entry in Brazil was compiled from the official government figures obtained in Rio last June.

Brazil's Imports of Automobiles in the Past 6 Years

NUMBER OF CARS IMPORTED FROM DIFFERENT COUNTRIES

Itajahy	0	0	0	2	2	0
Rio Grande do Sul	0	0	0	5	0	0
S. Borja	0	0	0	0	2	0

Two horizontal columns in this table are of especial interest, that showing imports in Rio de Janeiro and the other showing imports into the Port of Santos. In 1910 Rio led Santos at a five-to-one rate; the next year the ratio was four-to-one; the next year two-to-one; and in 1913 the two ports were practically on an even keel with regard to imports.

Then in 1914 came the turning of the tables, Santos jumping ahead of Rio. The war had a more serious effect on Rio than the Santos trade. The cars imported into Santos were not used in the city, but shipped into the great state of Sao Paulo. The reason Sao Paulo was not hurt so much by the war as Rio was largely due to the coffee situation. Coffee has been well handled during the war days.

But the Sao Paulo business during war days has largely been with the farming classes in the coffee area. Cars are not selling very rapidly in the City of Sao Paulo, but quite rapidly in the country. The City of Sao Paulo is surrounded by a wonderful coffee area, which has kept trade alive.

The city of Rio has been less fortunate. It is surrounded by mountains. It is shut in by hills around its celebrated harbor. The cars it imports it sells within the city. City sales have been literally dead for three seasons and so Rio's imports have been very low.

There are some other growing automobile centers in Brazil, as the tabulation will show. Porto Allegre is one of these. It is a city of 150,000 inhabitants situated on the edge of a long bay, with business concentrated in one long street along the water front. From this avenue very steep streets radiate up into the residential section. The paved streets are in a deplorable condition, converting automobiling from a pleasure into a torture.

This is the Union passenger depot in the heart of the city of Sao Paulo. It shows the modern spirit of the city. The wide street is ideal for motor truck and motor car traffic. In the city are many other new streets of equal width, and while there are narrower streets in the business section of the city, the use of motor trucks is not hampered by them as much as might be imagined. While the city has not more than 500,000 population, it has a go-ahead spirit which is destined to make it one of the greatest in Brazil. It is destined to be the great distributing center for the entire state of Sao Paulo, and the enormous state of Matto Grosso, one of the largest states in Brazil. Sao Paulo is also developing as a distributing center for other adjacent states

The business of Porto Allegre has always been overwhelmingly in the hands of Germans, this city being the center of that section of Southern Brazil in which you find entire German-speaking communities. Naturally the city cars are exclusively Benz, N.A.G., Mercedes, and other German makes. But within the last 2 years the Hinterland, the adjacent country, has absorbed nearly 200 Fords. Other U. S. A. makers have not got started here and when they establish themselves it will have to be for the country trade.

The entire total of automobiles in this section, which in addition to Porto Allegre includes Pelotas and Rio Grande do Sul, is from 600 to 800 cars. This total shows considerably more cars in the territory than the tabulation does, which is largely due to the sale of U. S. A. cars within the last season.

This is one of the busy business streets of Sao Paulo and is an example of the Spanish type of city. The street is so narrow that one way traffic is a regulation. This makes it possible to make good speed with a motor truck or motor car. There are many streets in the heart of the city of equal width, but fortunately there are many much wider, so that the use of motor trucks is as favorable as in Boston

Other Important Ports

The other leading ports for automobile importations are Para, near the mouth of the Amazon River; Manaos, half way up the Amazon and the center of the rubber industry; Pernambuco, a seaport town, with a preponderant colored population; and Bahia, the old capital of Brazil and a city which for years was a rival of Rio de Janeiro.

Unfortunately, many of these ports will never be the automobile consuming centers that Sao Paulo is because they have not the white population and have not the fertile, well-cultivated lands. As in U. S. A. so in Brazil, the sale of motor cars will be heaviest in those agricultural sections where the man cultivating the soil is able to purchase a car.

There is, however, one respect in which Rio is a most important truck center for the entire United States of Brazil. Being the federal capital, Rio has used the government for its own benefit and naturally to the disadvantage of other cities and the twenty states. In Brazil there is no free interchange of freight and merchandise among the twenty Brazilian states. If you ship from one state into another you must pay an export tax. To draw a parallel in U. S. A., suppose you are a manufacturer in Michigan and have to ship motor trucks into New York or Illinois; you would have to pay the state government of Michigan an export tax. This export tax is used by all of the states comprising the United States of Brazil as a source of revenue.

Map of Brazil, showing location of cities which are heaviest importers of automobiles and motor trucks

This situation gives Rio a position of peculiar importance in that there is no export tax on any goods shipped from the port of Rio into any of the twenty states of the country. This makes Rio the natural place to locate headquarters for Brazilian business, particularly if you purpose covering the entire country. With headquarters in Rio there is no tax for goods shipped to the State of Sao Paulo, or to such other states as Minas, Matto Grosso, Rio Grande do Sul, etc., etc.

There is still another way in which the City of Rio de Janeiro

has fortified itself as a truck center for the country, by use of government influences. From Rio radiate the nationally-controlled railroad lines which are the big distributing channels for much of the country. Further, the government steamboat lines which operate along the entire coast are worked to the advantage of Rio and the natural disadvantage of other ambitious Brazilian centers. Rio has built some solid foundation stones to guarantee her future as a business center for the entire country, as well as being permanently fortified as the political capital of the nation.

Now let us return to the State of Sao Paulo, the best motor truck market in Brazil to-day.

Coffee Plantations a Big Field

The coffee plantations of Brazil offer the greatest field in Brazil to-day for the use of U. S. A. motor trucks. Coffee planters have the reputation of being good spenders. That characteristic seems to have been in their blood before they became coffee planters. The coffee industry is largely in the hands of natives of the state rather than being controlled by foreign capital, as is so often the case with railroads, telephone system, telegraph system, water works, trolley lines and other utilities.

One of the great objections that will be raised to the more general use of motor trucks in the coffee industry will be the argument that horse labor is very cheap as compared with motor trucks. Many planters will be able to show in figures what it costs to haul the coffee by horse as compared with motor truck. All of this is quite true, but in spite of all these men have yet to learn of the many economies of motor trucks. They are not schooled in the better use of trucks. They merely look upon the truck as a substitute for horse labor. The grade of horse used in Brazil is very inferior to that in U. S. A. and undoubtedly the planters will not be slow to see that in the long run the motor truck is a good investment rather than being an expense or an experiment.

The motor truck is not new in the coffee districts, but it is there in relatively small numbers. You see large French, English and German trucks. Generally large-capacity vehicles are used of 5 tons or higher. You frequently see these large trucks being overhauled in the garages of Sao Paulo.

The lack of good roads will be advanced as a reason for not using motor trucks in the coffee areas. It is true that roads to-day are poor, but they are not too poor to admit of truck use. Roads are easily drained.

In the coffee country there is a distinctively wet and dry season. The wet season is the summer season when the growth takes place. In the dry season there is no difficulty with roads. We were through all parts of the state in the dry season and although roads were poor there were motor cars that were averaging 20 m.p.h. for distances of over 350 miles. Roads cannot be too bad when you make such averages.

Sao Paulo Best Truck Market

The best motor truck market in the United States of Brazil is in the State of Sao Paulo, which includes the majority of the great coffee area of Brazil and also includes the City of Sao Paulo, the Chicago of Brazil, and one of the best and most enterprising business cities in all of South America. To-day this area is a better truck market than the capital city of Rio de Janeiro, which has more than twice as many trucks in operation to-day as Sao Paulo city or the entire state. Rio is not an active truck market to-day, in fact, it is a very poor truck market. It is an over-supplied market. European makers stocked Rio 4 or 5 years ago. The city was oversold on trucks and there are to-day not a few Rio dealers who have large stocks of trucks on hand. One Rio dealer admits having over forty large trucks on hand, the majority of which he has had in stock for several years. He has sold over 250 trucks of his make in the city and is naturally quite burdened in carrying his present stock, which he has not been able to move for nearly three years.

(*To be continued*)

This large viaduct near the heart of the city of Sao Paulo is an example of the enterprising spirit of the city and is indicative of the general go-ahead spirit of the state of Sao Paulo. This viaduct carries double street car lines and is amply wide for all kinds of traffic in both directions. When you find a city adding street improvements of this nature you are certain it will be a profitable motor truck market

Aitken Wins Astor Cup at 104.83

Breaks World's Record for 250 Miles in Peugeot Without a Single Stop at the Pits—Rickenbacher Second in Maxwell—Vail's Hudson Third

SHEEPSHEAD BAY MOTOR SPEEDWAY, Sept. 30—With the delicate mechanism of his slender blue Peugeot working like a watch throughout the 250 miles of the Astor Cup race, Johnny Aitken broke the world's record for the distance here to-day in 2:23:04.03 averaging 104.83 m.p.h., without a single stop at the pits. His performance was 3:20:67 faster than the best previous time on the Sheepshead track, which was 2:26:24.7 made by Anderson in the Stutz last year.

Aitken was practically unchallenged for the race after Resta's Peugeot had succumbed to a broken intake valve at the 100-mile mark and Christiaens' speedy Sunbeam went out of the race with a broken connecting-rod on the following lap. Ralph DePalma was unable to repair a broken valve in his Peugeot in time to start.

Aitken drove a heady race, seeming to know just how far to force his car without straining it. His tires served him perfectly as is shown by his non-stop record for the race. Rickenbacher in the Maxwell, averaged 103.9 and Vail in the Hudson and LeCain's Delage both made over 97 m.p.h.

Ideal weather conditions prevailed, the day being almost identical with that on which the race was run last year. The crispness of autumn gave a tang of excitement and invigorating quality to the air. A snappy breeze drove light fleecy clouds across the blue sky and the bright sun furnished sufficient warmth to draw the sting from the atmosphere. The coolness of the day and the fact that heavy rains had fallen the day before had much to do with the small percentage of tire trouble during the race for the tires responded to these conditions by a greatly reduced tendency toward overheating.

40,000 Spectators

The stands were well filled when the thirty-one cars were lined up in rows of four for the start and streams of people were still crowding through the gates to swell the crowd to its total of 40,000. Most of those who came in automobiles were early and thousands of cars were parked within the inclosure, a goodly percentage being drawn up in the parking spaces within the oval.

In seven rows of four cars and with three in the eighth row the racers were sent off on the preliminary lap, crossing the line for a flying start at 2:31 with Christiaens' Sunbeam in the lead. The English mount of the Belgian driver was still in the van at the end of the first lap, closely followed by Resta and Aitken in their blue Peugeots, with Louis Chevrolet's Sunbeam close behind. These cars made a group slightly in advance of the rest of the field and as the race progressed they drew into the lead by a wider and wider margin, their speed averaging about 106 m.p.h., for the first few laps.

On the second lap Christiaens was still ahead but Resta had passed Aitken. On the fourth lap Chevrolet's terrific speed of 113 m.p.h. enabled him to forge to the front with

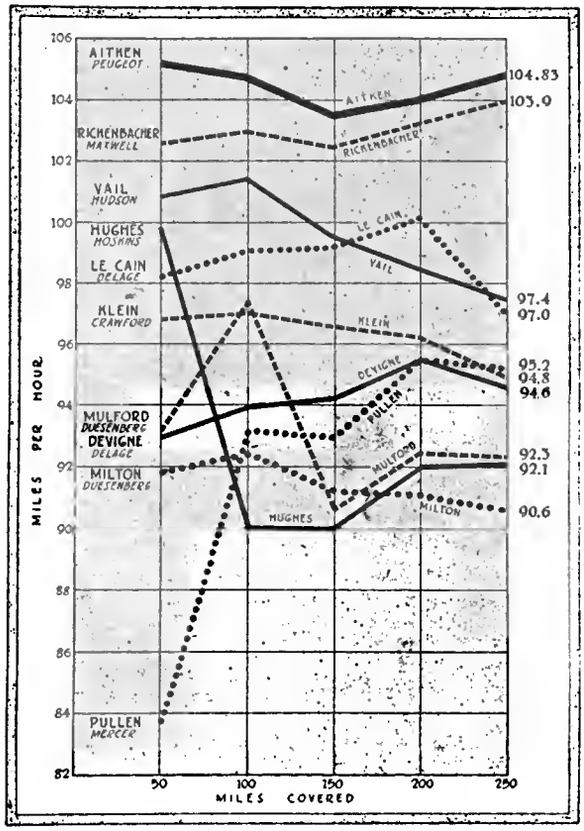
EDDIE RICKENBACHER
Second in Maxwell

IRA VAIL
Third in Hudson

Resta second and Christiaens third. For 10 miles Chevrolet and Aitken battled side by side in as pretty a duel of speed as was ever seen on the Sheepshead speedway. The Sunbeam crossed the 20-mile mark a few seconds ahead of Aitken but on the thirteenth lap Chevrolet's car gave up the battle and went to the pits with a burned-out bearing which terminated the veteran driver's hopes of victory.

After Chevrolet was eliminated Aitken held the lead with Resta second, forcing him like a veritable Nemesis, and Christiaens third, burning to avenge the withdrawal of his teammate. At 30 miles Resta swept into the lead and the spectators sent up a ringing cheer as he passed Aitken but the order was reversed five laps later when Aitken again swung into front position, Christiaens still hanging to third with bull-dog tenacity.

Passing Resta, Christiaens came into second place and for the next ten laps there was a thrilling struggle for supremacy between the dark, slender Peugeot of Aitken and the flashing nickeled Sunbeam of the Belgian. At the thirtieth lap Aitken had only a small margin of lead which he increased slightly by the time the 70-mile mark was reached, the other cars maintaining the same position.



Speed chart in miles per hour of the ten prize winners in the Astor Cup race at 50-mile intervals

Back in the field most of the cars had been lapped by the three leaders before the fortieth lap was over and there were evidences that the tremendous pace was telling as car after car dropped out at the pits, until the 100-mile mark drew near only twenty-two of the thirty-one starters were still circling the echoing speed saucer.

One of the biggest thrills of the race came in the forty-ninth lap when Resta's car was seen to falter and slow down as it sped out of the homestretch into the bank. Occupants of the stands and the bleachers rose to their feet in one great wave, pointing toward the back stretch where the Peugeot had drawn up beside the inner railing. A babel of exclamations and excited inquiries broke out and swelled in volume as the red fire truck swayed across the rough ground of the infield followed by a stream of spectators in cars and on foot. It developed that a broken intake valve had put the quietus on Resta's hope that the bad fortune which has followed him on the Sheepshead speedway would not prevail this year. In stopping, a small blaze broke out which caused an alarm of fire but driver and mechanic quickly smothered it.

As the news that Resta was out of the race spread through the stands a new cause for excitement developed when it was seen that Christiaens' Sunbeam, then in second position and battling with Aitken for the lead, had slowed up and come to a stop almost beside Resta's car on the very next lap of the track. A broken connecting-rod was responsible and after the other cars had made many laps the two unfortunates appeared around the bend leading to the homestretch pushed by drivers and mechanics in a mournful procession to the pits.

Aitken was now far in the lead and the only cars that seemed likely to challenge him for that position were the two

*Only finish times available.

A view down the homestretch of the Sheepshead Bay speedway during the Astor Cup race, showing the grandstand crowd and the front of the pits. The police and members of the technical committee kept this space clear

Maxwells, the Hudson and the Duesenberg, which were having many fascinating speed brushes on the turns and straightaways as they fought for the privilege of passing the Peugeot. Lewis' and Galvin's Premiers and Wilcox's Peugeot had been forced to give up the race because of burned-out bearings. A broken connecting-rod had disposed of Henning's Ogren and a leaking intake was responsible for the elimination of McBride's Olsen.

After the Sunbeam had been put out of the running Richenbacher and Henderson took second and third positions and alternated in this order for a good part of the balance of the race. Mulford's Duesenberg was leading Vail in the Hudson with Milton's Duesenberg trailing.

The only accident of the day occurred on the sixty-first lap when Ruckstell's Mercer blew a tire at the top of the bank on the turn running into the homestretch and tumbled to the bottom of the slope, with driver and mechanician trapped in the seat. Ambulances, physicians, race officials and the fire truck hurried to the spot where a cloud of dust surrounded the wrecked racer. A cheer of relief went up from the spectators, all of whom had risen to their feet as the yellow car hurtled across the track, when they saw Ruckstell and his mechanic, Quicksell, crawl from beneath the overturned machine and rise to their feet. The only injuries sustained, it developed, were a few bruises by Ruckstell and a sprained shoulder by his mechanic.

Ruckstell crawling from beneath his overturned Mercer after it tumbled headlong down the steep, high incline

During this time Aitken had been increasing his lead, being nearly 2 min. ahead of the record for the distance at the 150-mile mark. Henderson's Maxwell was in second position at this stage of the race with Rickenbacher close behind fol-

A lively brush. The cars are, left to right, Aitken's Peugeot; Moore's Crawford; Christiaens' Sunbeam; Klein's Crawford; Resta's Peugeot, and Henderson's Maxwell. Speed is indicated by position on bank

Resta pushing his disabled Peugeot to the pits. Christiaens was close behind him with the silenced Sunbeam

lowed by Mulford, Klein in the Crawford, Vail in the Hudson and Milton's Duesenberg. This order continued lap after lap. At the end of the eighty-fifth lap Aitken had averaged 104.1 m.p.h., Henderson's Maxwell was still second but Milton's Duesenberg had taken the third position from Rickenbacher. It was now 4:15 and a number of the spectators, evidently considering the race won by Aitken, began to leave the stand. The great majority, however, continued to watch the speeding cars with intense interest.

At 200 miles Aitken had lifted his average speed to 105.75 m.p.h. Henderson was still second having covered 196 miles while Rickenbacher and Mulford were in the same lap. Milton was in fifth position at this point with Vail sixth, LeCain seventh and Pullen eighth. Aitken's time was 1:53:25.55 for the 200 miles or nearly 3 min. ahead of the record made in last year's Astor Cup race when the distance was negotiated in 1:56:21.40.

Henderson's Maxwell went out just after the 210th mile because of engine trouble, leaving Rickenbacher to overtake Aitken. This he tried in vain to do as the Peugeot driver was safely ensconced in first position and his car was running as smoothly as at the start of the race.

Vail in the Hudson did some sensational driving, during the 6 miles following the passing of the 150-mile mark, which probably enabled him to finish in third position. He had been close behind the leaders but apparently had not tried to maintain the high speed which had characterized them. At this point, however, he deliberately set out to win a place among the cars in the van. His Hudson shot forward as though suddenly unleashed and rapidly overhauled the cars between him and the

Aitken winning the 250-mile Astor Cup race after breaking the world's record for the distance. Note how the stand has filled up since the start

Photographs by International Film Service

leaders, passing first Klein in the Crawford and then Mulford in the Duesenberg. After a bitter battle he succeeded in passing Rickenbacher, his spurt placing him in third position with only Aitken and Henderson ahead of him. By the time the 200-mile mark had been reached, however, Rickenbacher again shot ahead of Vail and settled into second place when Henderson went out at the 210th mile, with Vail third.

When the uncertainty which clouded the order of finish of the other cars had been cleared away, LeCain's Delage was found to be in fourth position with Pullen's Mercer fifth, Klein's Crawford sixth, Devigne's Delage seventh, Mulford's Duesenberg eighth, followed by Hughes' Hoskins, Milton's Duesenberg, Meyer's Pugh, Adams' Adams Special. D'Alene's Crawford and Burt's Ogren, in the order named.

Some difficulty was experienced with the scoreboard early in the race owing to the failure of the electrical apparatus but the board was put in partial operation later in the race so that the positions of the leading cars were available. As the race neared its close spectators broke away from the restraining guards and ran across the track in the path of the speeding cars, seemingly reckless risk.

A temporary diversion, which, however, might have been the cause of an accident, occurred during the first 100 miles when a number of toy balloons were seen bouncing and floating along the track in front of the grandstand, threatening to fly into the faces of the speeding drivers. Starter Wagner darted onto the track during intervals between passing of the cars and captured the roving spheres, greatly to the amusement of the spectators.

Precautions against fire at the track were very thorough, many of the cars carrying J-M and Pyrene fire extinguishers, while in addition the H. W. Johns-Manville Co. stationed a squad of fifty men equipped with its extinguishers at various points around the track.

Pit Work a Minor Factor

THE limited amount of tire changing in the Astor Cup race did not permit of much comment on the training in this direction, as practically in all cases the change went through smoothly and did not occur at a vital period in the race. In locating the cause of trouble a little uncertainty could be noticed among the drivers where mechanical failures had occurred. For instance, where one of the cars had come into the pits with engine trouble the mechanic and driver labored for some time trying to start the engine after it could be seen that every revolution of the starting crank caused a puff of steam to jet from the radiator. This plainly showed that there was a breakdown between the cylinder and the water-jacket space and the case was hopeless, but still the driver and mechanic labored on.

Eight Broken Connecting-Rods

There were forty-five stops made at the pits. Of this number nine were permanent, and there were other cars which went out that did not reach the pits. Most notable of these were Resta and Christiaens who went out on the backstretch almost simultaneously when running even and well up in the lead. Of the cars that went out, broken connecting-rods take the lead as a cause of trouble, eliminating eight.

Owing to the cool weather and the shorter distance tire troubles were comparatively few. Pullen in his Mercer car had more trouble in this direction than all the other thirty-one starters put together, as he changed five tires while no one else changed more than one, and in fact there were only three other tire changes, by Vail in the Hudson, Klein in the Crawford, and Gable, of the Erbes team. None of the tires were blown or thrown in this race, and there was a notable improvement in the manner in which the treads clung to the tire body as there was not one case of separation; whereas the principal cause of tire failure in the races of last year was the tearing off of the tread.

Oil Supply a Problem

The regulation of the oil supply continues to be the stumbling block for many drivers. Eleven times drivers drew up to the pits either to change or clean plugs. Adams, in the car bearing his own name, was the leader of the spark plug changers as he had three stops on this account. Carbureter adjustments were made by Mulford on the Deusenberg, on Chandler's Crawford and on the Ogren.

Probably the most interesting stop was made by Henning's Ogren for engine trouble, a careful inspection showed all the mechanism to be in good order. On cranking the engine, however, there was no suction through the carbureter and finally a blow-hole was located in the intake manifold. This was sealed with shellac and tape but the temporary repair could not stand the vibration and heat and consequently the car had to be withdrawn.

PIT STOPS IN THE ASTOR CUP RACE

Car	Driver	Cause of Stop	Duration of Stop
Mercer	Pullen	Right front tire	20 sec.
		Change spark plugs	4 min.
		Right rear, gas, oil	1 min. 15 sec.
		Right front tire	35 sec.
		Right front, left rear, oil	1 min. 32 sec.
Hudson	Vail	Right rear tire	20 sec.

Olsen	McBride	Out—burned out rod	
Olsen	Watson	Oil leak	2 min.
		Change plugs, oil leak	11 min.
		Change plugs	10 min.
Pugh	Meyer	Gasoline	1 min. 30 sec.
Ogren	Burt	Adjusted carbureter	2 min.

Preparedness Is Race's Lesson

Few Engineering Lessons Found in Analysis of Troubles —Many Old Causes of Failure Now Seem Conquered

A HIGH-SPEED racing car is always working just on the edge of failure. The reciprocating parts and the the lubrication especially are liable to fail at any instant; the factor of safety is somewhere down in the decimal points. This being so the failure of a part like a valve or connecting-rod is not to be laid at the door of its designer; the explanation why one rod in four broke and not the other three is probably to be found in some trifling difference in the homogeneity of the steel.

In the Astor Cup race nothing new transpired that is of important to engineers, the big, striking thing was the wonderful showing made by the tires. The engineering of the racing cars is just about what it was a year ago or more, the quality of the tires is ten times as good at least. Not only has their durability and sheer strength been increased, but their average of performance is much more nearly even. Loose treads seem a thing of the past. This means much for the ordinary car user in the ultimate analysis, for it means that we shall soon have tires at least twice as good as those we have to-day.

Importance of Being Ready

In the mechanical preparation for first class events there has been great improvement in the past 2 years, but there is still room for plenty more. The leading racing teams seldom lose a car except from the actual breaking of an important part. The lesser lights of the speedways usually retire by reason of something they could have prevented easily. If some part breaks it is perhaps ill luck, if some part comes loose it is surely carelessness and nothing else. The spark plug trouble has been cured entirely from the plug maker's viewpoint. It is rarely now that plugs fail except where they do so through too much oil reaching them. If they flood and soot it means that the driver did not take proper precautions in setting his lubrication system.

The running of Vail's Hudson is a paramount example of what can be attained by *work*, by making sure of everything. Some of the cars built individually by their drivers are similar monuments to the genius expressible by the taking of infinite pains. On the other hand, a job hastily assembled will almost always give trouble and will seldom stay the course. To-day any good mechanic can build himself a racing car which will win prizes. He can buy stock engines which will give all the power necessary, he can get axles and frames which are suitable for the job. Such a car is not likely to win first place in an important event, but it can be sure of finishing at a good speed, if it is got ready carefully enough. To manufacture racing cars would be impossible; to build them calls for nothing more than patience and thoroughness in detail.

It is a pity that interest in a race centers so much around the winner. For really sporting competition the struggles between the men who take places from the fifth downwards are an enthralling spectacle to watch. There will always be comparatively few cars standing right at the top of the tree, but we could build any number that would make close seconds. At the present moment a car that will average 100 m.p.h. is difficult to create, but one which will average 95 is fairly easy to build. For every car in the 100 class we could have fifty in the 95 m.p.h. bunch.

Of course it is always working upward. In a year or two we shall have the front rank cars averaging 115 miles or better, but by then the second rankers will have moved up a bit. If American speedway racing can be arranged so as to provoke keen contests between cars of approximately equal speed ability we could do without the front rank cars.

Specifications and Details of Equipment of Cars in the 250-Mile Astor Trophy Race

NOTE—All cars four-cylinder, except those marked (*). All cars equipped with Hartford shock absorbers and Boyce Moto-Meter.

The Awakening of Russia

Five Factories To Produce 7500 Cars and Trucks for Government — Roads and Car Markets

The author, Nicolas Kouznetzoff, at the wheel of the first Overland car to be brought to Russia. It was taken there in 1909. The illustration gives an idea of the quality of roads in Finland, these being generally bad, sandy and rocky

¶EDITOR'S NOTE.—*Nicolas Kouznetzoff, civil engineer, of Petrograd, and president of the Technical Committee of the Automobile Club of Petrograd, is on his second visit to the U. S. A., where he has been sent to investigate the farm tractor and motor truck industry. He was here less than a year ago on his first visit when he acquainted himself with the leading automobile factories and reported to his country on the development of the industry in the U. S. A. He has been closely connected with all of the engineering and sporting phases of the automobile industry in Russia.*

ONE result of the European war upon Russia is that the country has already started to develop the manufacture of automobiles. Previous to the war little automobile manufacture was carried on in Russia, the majority of the machines coming from Germany, France, Italy and England, all of which concerns built colonial type models to meet the requirements of rough Russian roads. The war has demonstrated to Russia how necessary it is to have automobile factories, and five new factories have already been started, the government being largely responsible for this activity. According to government arrangements, these five factories must produce 7500 motor trucks and automobiles in a given time, this meaning a production of 1500 vehicles each. The minister of war has already placed orders with these five factories for all of this output.

The new car factories which have been started are as follows:

Axaj Co., Rostov-on-Don.
V. Lebedev Co. of Jaroslav.
Russian Reno Co. of Rybinsk.
Riabushinsky & Kouznetzoff Co. of Moscow.
Russo-Baltic Car Works of Moscow.

The automobiles to be manufactured by these concerns will be almost entirely of Russian make, and only a few of the necessary parts not yet manufactured in Russia are permitted to be imported, for instance, magnetos, spark plugs, ball bearings. In order to enable the above mentioned factories to attend to their orders, a number of auxiliary plants are being established in Russia for the purpose of manufacturing different automobile supplies. Every one of the above factories has adopted some foreign type of an automobile to be used as a model, with the exception of the Russo-Baltic Works, which are going to build their own type of an automobile, and which have been supplying the entire Russian market for a number of years with automobiles.

The Reno factory is going to build the French model.

Riabushinsky & Kouznetzoff are going to follow the Italian plan of Fiat.

Lebedev is going to build after the drawings of the English works of Crossley.

The Axaj works have not decided as yet what they are going to manufacture. All of the works mentioned above are erecting their buildings at present, and some of them are already beginning to equip their factories. Some of the factories have sent their representatives to America, authorizing them

Lower—Mobile tractor used by the Russian army in typical hauling service. It is drawing four heavy guns

Map of Russia in Europe, showing the cities which give most promise of some day becoming the leading automobile cities of the empire. The heavy lines radiating from Moscow and Petrograd indicate roads which are largely used for automobile travel at the present time. Another road connects Sebastopol and Sukhum Kale. Russia is a country of vast distances, huge forests and great plains, called steppes, large areas also being covered by impenetrable swamps. These conditions have been largely responsible for Russia's backwardness in automobile development

to order and purchase the necessary equipment for the new factories to make production possible.

Central Part Is Best Field

Russia is a country of great distances, of great agricultural areas and great forest areas. That part most favored for automobile use is in the central vicinity surrounding Moscow and in the large agricultural areas extending in all directions from the south of Moscow. When you get within 200 miles of the Black Sea the country becomes sandy and is not so favorable for motor car use.

Naturally, the cars will be used more in the large cities, which are at present well stocked with European models. Good roads radiate from the cities. From Petrograd to Moscow, 450 miles, the distance can be covered in 2 days easily. In a race it was covered in 9 hr. and 20 min., or 48 m.p.h. When touring it is customary to stop at the small town of Vishni Volotchok, which is a midway point. The country be-

tween Petrograd and Moscow is largely covered with forest.

From Petrograd to Helsingfors in Finland there is a good macadam road and the 275-mile trip can be made in 8 hr. Helsingfors has a population of 200,000 and about 3000 automobiles and trucks.

From Petrograd to Pskov, which is in the direction of Austria-Hungary, there is a good macadam road, making an 8-hr. trip between the two cities. From Pskov to Riga there is a good road. Riga was the home of the biggest Russian tire factory, Prowodnik, which soon after the outbreak of the war was moved to Moscow, where only recently the manufacture of tires has been commenced in the new factory.

Very recently an automobile test has been started from Petrograd to Archangel, the port on the White Sea. The road leads by way of Petrozavodsk on Lake Onega.

Good Roads from Moscow

More good automobile roads radiate from Moscow, which is centrally located, than from Petrograd. Leading to the south are good highways to Kiev, to Kharkov, and to Saratov.

That part of Russia lying to the north and east of Moscow is generally covered with great forests and the use of automobiles is very limited.

There are some good roads in the southern part of the country, one in particular leading from Sebastopol on the Crimea, the center of the Crimean war of 70 years ago, to the east. This road is very scenic and leads as far as Sukhum-kale on the eastern end of the Black Sea.

Perhaps the best roads in all of Russia are to be found in Poland, which is now in the hands of the Germans.

There will doubtless be a good market for motor cars among the wealthy farmers of Russia. The farming class roughly divides itself into large farmers, known as Pameshik, and the small farmer, known as Mujik, only a little over 12 per cent of the population being urban in European Russia. The former is a large landowner who can afford to buy several motor cars and many farm tractors. They have huge areas of land, some estates being as large as some of the smaller States in the U. S. A.

The Russian government has already realized the necessity of motor power on farms and has ordered twenty-three different makes of American farm tractors. These are the latest types and the Russian minister of agriculture has purchased them with the object of studying the tractor situation. Undoubtedly these will be but the forerunner of large orders of U. S. A. tractors. It is not impossible to conceive the time when factories will be started in Russia under government stimulation to build farm tractors.

To Popularize Tractors

In order to popularize tractors with Russian farmers the Russian minister of agriculture is at present planning to form ten special tractor squads, whose duty will be to demonstrate tractors to Russian farmers in different sections. Each squad will have five tractors at his disposal. In order that these demonstrations may be successful and that the tractors will be well handled, the government is organizing special classes for teaching the mechanics of tractors. It is a part of the plan to purchase 300 tractors during the coming year.

Besides agricultural tractors the ministry of war is specially interested in all kinds of tractors used for the purpose of transporting artillery loads. During the present war the tractors have proved to be invaluable and have already replaced the work done by horses in a number of branches of industry.

For the last 2 years, due to the war, Russia, being an agricultural country, is suffering a shortage of laborers and especially horses for all kinds of agricultural work. The lack of horses and of the possibility of getting them 4 years ago raised the question of finding new methods of agricultural work. The only way out of the critical situation is the introduction of tractors which will play an exceedingly important part as a substitute for horsepower.

There are about 20,000 miles of State road in Russia and approximately 475,000 miles of country road. The State roads are distributed among the various provinces as follows:

Province	Miles
Moscow	1500
Petrograd	1200
Warsaw	1100
Grodno	1000
Tiflis	1000
Ekaterinoslav	950
Volhynia	800
Piotrkow	700
Tavrichevsky	650

In all the other provinces combined there are less than 600 miles of State roads.

Russia produces annually 200,000 tons of gasoline and 1,400,000 tons of kerosene. Before the beginning of the war gasoline sold for 23 to 33 cents per gallon, depending upon the quality, but now the price ranges from 30 to 45 cents per gallon. Kerosene has also advanced in price 2 cents per gallon, selling at 10 cents now as compared with 8 cents at the time when Russia entered the war.

—

189,610 Cars Registered in 58 California Counties in 6 Months

SACRAMENTO, CAL., Sept. 30—Registration of 189,610 cars and 1254 automobile dealers has been reported for the first 6 months of 1916 by the fifty-eight counties of this State, including sixty-one non-resident cars. This is the first detailed report made by the counties. The statistics, including cars, motorcycles, chauffeurs and dealers, follow:

County	Cars	Motorcycles	Chauffeurs	Car Dealers
Alameda	13,311	1,948	547	60
Alpine	12	...	...	..
Amador	352	23	17	2
Butte	1,640	241	42	12

Above — A White Red Cross ambulance in the service of the Russian army drawn up in company with two White touring cars and several Opels used by officers. The White touring cars are to the left of the ambulance

Above—A line-up of automobiles requisitioned by the Russian army authorities for war service. They are a heterogeneous lot, comprising everything from light touring car chassis to heavy motor trucks. Most of them, however, are medium weight chassis. All have been fitted with army bodies

Above — A Delaunay-Belleville touring car mounted on a freight car on its way to the front for service with the Russian army

Right — An armored car which was one of several captured by the Russians from the Germans. Note the steel wheels and heavy armor plating, the latter protecting both rear wheels. A machine gun is carried in the revolving turret

Engineers To Specify Ideal Truck

S. A. E. Committee Drafting Specifications for Nominal 1½-Ton Truck Making for Ideal Without Regard to Current Practice of Manufacturers—Specification Will Be Submitted for Criticism to All Interested

By A. Ludlow Clayden
Chairman S. A. E. Standards Committee

THERE are two ways an army can buy trucks. One is to draft a specification which covers a few essentials but is not so rigid that it will not permit the purchase of existing trucks. This is good for war time or when there is a hurry call for vehicles.

The other, and the better way, is to get an ideal specification with close definition on everything that affects interchangeability and with latitude on non-essentials only. To say to the industry "this is what an army truck should be, and if you like to build a truck on these lines you will have no changes to make if an army order is out for bids."

This was done by Great Britain some years ago. A committee of engineers was appointed and they specified certain parts very accurately. Many different truck makers started building trucks which fitted the specification, trucks different in many respects yet as one in some vital points. War proved that the British scheme did not go far enough in some ways, and that some of the things insisted upon were not important. The scheme will be revised after the war. Meanwhile the S. A. E. through its truck standards division and its members generally is drafting a specification which might be entitled "the American engineers ideal army truck."

Ideal Army Truck

A recent meeting or two held to discuss an army specification showed that the building up of an ideal specification would be a long job. It also showed that a specification drawn so widely as to admit many standard trucks as now built was of little use. It was for this reason that the society took up the task of making an ideal specification. It is impossible to say to what use the specification may be put. It may never be used or it may be used extensively. The immediate object of the society is to have the truck engineers of America go on record as to what they think an army truck should be. As to what parts of the design need rigid specification and what parts can be left to the individual manufacturer.

To get a start H. D. Church, chairman of the truck standards division and chief engineer of the truck department of the Packard Motor Car Co. drafted his idea of a specification; which is noteworthy in that many of its provisions call for things which are not Packard practice. This specification was, on Sept. 28, discussed by the truck standards committee and some changes were made here and there.

There are to be many more meetings. While the committee are working they will enlist the help of the whole industry. They will seek criticism and advice from any truck man who will study the specification carefully and write a letter or come to a meeting.

One thing is to be remembered above all others. Nobody who has begun work on this specification has any axe to grind. The specification will not fit any existing truck. If anyone wants ultimately to build one to fit it they will have to start from the ground up.

The following pages contain the specification as put up for criticism after the first meeting of the truck standards division. Before the society feel that agreement is close enough to call it a really ideal specification it will no doubt be altered in many respects from what it is now. *At present it is to be regarded only as a groundwork, as a foundation upon which the specification for the ideal army truck can be built.*

Tentative Standard Specifications for 1½-Ton Capacity Gasoline Military Motor Trucks

1. The number of trucks required will be stated in the "Instructions to Bidders," issued by the Purchasing Quartermaster. The prices quoted will be f.o.b. factory, and the truck must be complete in every respect, and in proper operating condition.

2. *Manufacturers:* Each bidder must submit a complete list of manufacturers and location of factories furnishing any part, either finished or unfinished, assembly, or accessory, which is used in the construction of the trucks, and not made in the factory where the trucks are constructed. This shall not be construed as including bar or sheet stock or structural material. If this information is not given, the proposal may be rejected, or in case the proposal is accepted, the Quartermaster Corps reserves the right to name the manufacturer and select the material, apparatus, parts, or accessories, and no others will be substituted for those named.

3. *Employment of Convict Labor:* In the performance of work herein specified the contractor shall not, directly or indirectly, employ any person undergoing sentence of imprisonment at hard labor, which may have been imposed by a court of any State, territory, or municipality having jurisdiction, nor permit such employment of any person furnishing labor or material to said contractor in fulfillment of this agreement.

4. *Patents:* The contractor shall for all time secure to the government the free and undisputed right to use any and all patented articles used in the work, and shall defend at his own expense any and all suits for infringement of any patent or patents, and in case of adverse claims under patents, the contractor shall pay all awards.

5. *Interchangeability of Parts:* All parts of trucks must be constructed to definite standard dimensions, and proper tolerances, so that any part of same may be replaced and properly fitted and adjusted without requiring additional tool work or machine work on the parts.

6. *Materials:* A complete list of all materials used in the construction of the various parts of the truck must be given,

together with the chemical composition, and physical properties of same.

7. *Drawings and Data:* Each bidder will be required to submit complete dimensioned detail and assembly drawings, showing the size and construction of every part of the truck. These drawings must show the shop limits on all parts, and a reference number or letter referred to the list of materials, physical properties, and heat treatment, which list will also be submitted with the proposal. The drawings must be arranged in proper order for filing, and provided with a suitable index which will enable any individual drawing to be readily located. The drawings and data above referred to will not be opened publicly with the proposals, but will be considered confidential. The drawings and data may be submitted direct to the Quartermaster General, Washington, D. C., and should be referred to in each proposal which is submitted.

8. If the drawings and data herein required are on file in the office of the Quartermaster General, they need not again be submitted with the proposal. If any major changes have been made in the construction of the truck, materials used, or methods of heat treatment since the drawings and data were submitted, details of those changes should be submitted with the proposal.

Service Station Data

9. *Service Stations:* Complete information regarding the location of all service stations, the floor area of each station, and the number of men employed in each service station, should be submitted with the proposal.

10. *Departure from Specification Requirements:* In case the vehicle on which proposal is submitted does not comply with these specifications, in every particular, the bidder must state definitely in what particulars the vehicle which he proposed to furnish does not comply with specification requirements.

11. *Guarantee:* Each bidder will be required to guarantee his vehicle or vehicles against defects in material or workmanship for a period of one year. This guarantee shall include the delivery of the defective part or parts to any point in the United States. After the installation of the new part, the defective part will be returned to the manufacturer if he so requests. The manufacturer will pay the transportation charges on all returned parts.

12. *Load Capacity:* The normal load capacity above the chassis, including body, shall be 4480 lb. The maximum load capacity above the chassis, including body, shall be 5080 lb.

14 M.P.H. Maximum Speed

13. *Road Speed:* The maximum road speed shall be 14 m.p.h., obtained by maximum motor piston speed on high gear of 1100 ft. per min., limited by governor.

14. *Engine:* Engine shall be located in front, under a hood, and shall be of the four-cylinder vertical type, with a piston displacement of not less than 300 cu. in.

Mechanically operated interchangeable poppet valves are to be used. Valve stems and springs are to be completely enclosed by dust and oil-proof covers which must be readily removable.

Crankshaft must have not less than three main bearings.

Circulating Lubrication

Lubrication must be circulatory, with at least 2 gal. capacity in the oil pan. There shall be pressure feed from the pump to the main crankshaft bearings. If splash is used for connecting-rod lower end bearings, it must be so controlled that the amount of lubrication is not affected by any grade up to 25 per cent, or by a certain transverse inclination. Spray lubrication for other parts of the engine will be acceptable. A screen shall be fitted on the inlet side of the oil pump of a design which will not require cleaning more often than once in each 1000 miles of vehicle operation. A screen must be provided between the crankcase oil-filler and the oil pan, and provision must be made to prevent its ready removal or intentional injury. A settling basin with drain must be provided in the oil pan, and the oil pump inlet must be above level of same.

Ignition by high tension magneto, with battery ignition for starting.

Magnetos must be gear-driven, made to S. A. E. standards, and must be interchangeable in every respect, including mounting. Magnetos must be arranged for *clockwise* rotation and be properly protected from water. For interchangeable magneto specifications see S. A. E. Data Sheet 36, Vol. I.

Timing Marked on Flywheel

To enable the timing of the valves and ignition to be readily set, the flywheel is to be clearly marked for the opening and closing of both inlet and exhaust valves, and for the magneto setting on full retard, and a suitable pointer is to be provided with which the flywheel marks can be aligned when timing the engine.

All ignition wiring must be protected from water and oil and mounted in such a way as to prevent chafing.

Engine must be mounted on a three-point suspension.

Oil pan must be removable without disturbing any of the main bearings or the clutch housing.

Carbureter must be so designed as to properly handle gasoline of the following specifications: (Not settled.) The carbureter must be provided with a readily removable wire mesh gauze strainer in a sediment pocket under the float chamber, and sediment pocket must be provided with a drain cock of the snap-lock type.

Provision must be made to keep dust out of the carbureter air intakes, crankcase breather and oil filler.

Provision must be made to prevent oil leaks at any point in the engine.

To prevent mud and water being spattered up into the carbureter or ignition apparatus, some form of protection must be fitted between the sides of the crankcase and the frame, either in the form of cast webs on the crankcase, or rigidly mounted metal pans extending from the frame sides to the main barrel of the crankcase. Full engine shields extending clear across the frame will not be accepted.

15. *Cooling System:* Water cooling must be used, with forced circulation by centrifugal pump, which must be of a design to permit thermo-syphon circulation in event of pump failure.

Radiator must be of the vertical individually finned tube type, with detachable upper and lower tanks. All radiators must be interchangeable and constructed as per drawing. Radiators must be flexibly mounted, to prevent strains from any frame distortion.

Cooling Water Drain

A drain-cock which will drain all the water from the entire cooling system must be fitted in a location where a bucket can be readily placed directly beneath the drain. This drain-cock must have a clear bore of at least ⅜ in., and must be fitted with a spring-snap lock to hold it in the closed position.

All suction hose connections must be provided with means to prevent collapsing.

Belt-driven fan shall be used, with a 28-deg. endless V belt of 1¼ in. width, and means of belt adjustment must be provided.

A radiator guard must be furnished, in accordance with drawing.

16. *Hood:* Hood with water-proof top must be fitted. Hood must be of a type which can be completely removed or opened up wide for engine inspection or adjustment.

Hood must be supported independently of the radiator.

Folding Starting Crank

17. *Starting-Crank:* Starting-crank must be arranged to fold up when not in use, in such a location that it will not be damaged by minor collisions. Detachable starting-cranks will not be accepted.

18. *Clutch:* Clutch must be of dry disk or dry plate type, with either a spring adjustment, or a spring sufficiently long to automatically compensate for wear on disk surfaces.

The steel clutch disks must be properly hardened.

All thrusts must be self-contained when clutch is engaged.

Clutch release must be fitted with ball bearings, with adequate provision for lubrication.

A large clutch brake must be fitted, and the entire clutch and release bearing must be enclosed in a dust-proof housing.

Plain clutch thrust-bearings will not be accepted.

19. *Front Universal Joint Shaft:* If universally jointed shaft is used between clutch and transmission, it must be equipped with two universal joints. Either the metal to metal or fabric disk type of joint will be accepted. In either type, provision must be made to prevent the shaft from whipping loose in event of joint failure. If the joints are of the metal to metal type, they must be thoroughly enclosed, and provision made to obtain lubricant.

Sliding Gear Transmission

20. *Transmission:* Transmission must be of the sliding gear type, with four speeds forward and one reverse, the various gear ratios to come within the following percentage limits:

High speed.....100%
Third speed.....
Second speed..... } Await suggestions
Low speed.....

Reverse: As low as or lower than low speed.

Transmission shaft pilot bearings must be either on ball or roller bearings, as plain bearings at this point will not be accepted.

Transmission must be so mounted as to be unaffected by chassis frame distortion.

Provision must be made to prevent oil leaks at any point.

Sufficient lubricant must be carried for 300 hr. operation without renewal or replenishment.

21. *Propeller-Shaft:* The propeller-shaft must be fitted with two universal joints and a slip joint. The fabric disk type of universal joint will not be acceptable.

Universal joints and slip joint must be completely enclosed, and provision must be made for retaining lubricant.

At the front end of the propeller-shaft, provision must be made to prevent shaft from whipping loose in event of failure of the front universal joint.

Hotchkiss Drive Banned

22. *Connection Between Rear Axle and Frame:* The driving connection between the rear axle and the frame may be of the type using radius-rods and torque-arm, or radius-rods only, with the springs taking the torque.

The Hotchkiss drive, transmitting both torque and thrust through the rear springs, will not be accepted.

23. *Rear Axle:* The rear axle may be of the worm gear type, or a double reduction gear type with the reduction gearing in a central housing.

The rear axle design throughout must be such as to entirely house all the driving mechanism, and provision must be made to prevent any escape of lubricant.

Sufficient lubricant must be carried in the axle housing for 300 hr. of service without renewal or replenishment.

The differential must be of a type which will drive one rear wheel when the other wheel loses traction.

24. *Front Axle:* The front axle must be a steel forging.

Plain or ball bearings will not be acceptable for the front wheels.

Positive stops must be provided to limit maximum steering angle of front wheels, which must be sufficient to give a minimum turning radius, measured to outside of front wheel track, not to exceed 28 ft.

Steering-knuckle tie-rod must be located behind the front axle. (Many opinions wanted on this.)

25. *Wheels:* All wheels shall be of cast steel and interchangeable, although not necessarily identical as to design. Standardized dimensions which will be required are shown on drawing.

36 by 4 Tires

Wheels shall be of the proper size to take 36 by 4 in. single front tires and 36 by 4 in. dual rear tires.

26. *Tires:* Solid tires must be used—36 by 4 in. single front and 36 by 4 in. dual rear, S. A. E. standards, of makes either approved by or specified by the War Department.

27. *Tread:* Front, 56-57-in. center to center front tires. Rear, 56-57-in. center to center between dual rear tires.

28. *Springs:* Front and rear springs must be half-elliptic.

Springs shall be equipped with suitable rebound clips, and the second leaf from the top shall be wrapped around the spring eyes to give assistance to the top plate on rebound.

Springs with shrunk-on center bands will not be accepted.

Rubber or spring buffers must be fitted front and rear to cushion blow of frame on axle or spring center under maximum spring deflection.

11 to 13 Ft. Wheelbase

29. *Wheel Base:* Wheel base must not be less than 11 ft. nor more than 13 ft.

30. *Frame Length:* Frame length back of driver's seat available for body, 10 ft. 5 in.

31. *Load Distribution:* Load distribution arranged to carry between 80 and 95 per cent of load above chassis on the rear tires.

32. *Control:* Control levers, including gearshift lever, brake hand lever, clutch pedal, brake pedal, accelerator pedal and spark and throttle hand levers, must be in accord with S. A. E. standards.

Flanges must be fitted on the clutch and brake pedals to prevent the driver's feet from slipping off.

The pressure on the clutch pedal pad necessary to disengage the clutch should not be more than 90 lb. nor less than 70 lb.

33. *Steering Gear:* The steering gear may be of the screw and nut or the worm and wheel type.

The ratio of movement between the steering hand wheel and the front road wheels shall be such that for 360 deg. travel of the steering hand wheel, the road wheels will move not to exceed 30 deg. about the steering knuckle pivot. (Many opinions wanted on this.)

Throughout the steering gear, including all steering connection joints, adequate provision must be made for lubrication, and all steering connection joints must be protected by leather boots.

Electric Lighting

34. *Electric Lighting Equipment:* Current for electric lighting must be furnished from a 6-volt 100-amp. hr. storage battery and gear- or chain-driven generator on engine.

All wiring must be enclosed in metal conduits.

The following lamp equipment will be required:

Side-lamps—combination oil and electric, with 15 candlepower bulbs.

Tail-lamp—combination oil and electric, with 2 candlepower bulbs.

Side- and tail-lamps and side-lamp brackets must be interchangeable, as per drawing.

One swivel electric searchlight with 8 in. lens and 21 candlepower bulb, mounted on dash.

An electric instrument lamp with 2 candlepower bulb must be furnished, and also an 8 candlepower inspection lamp with 15 ft. removable socket cord.

35. *Road Clearance:* The following minimum road clearances must be maintained:

Under center of front axle, 9¾ in.

Under center of rear axle, 9¾ in.

Under flywheel housing or flywheel, 13 in.

36. *Brakes:* Two independent sets of double acting brakes must be equipped, either both or rear wheels or with one set on rear wheels and the other on transmission line back of transmission.

Brake Adjustments

Brake adjustments must be readily accessible, and must be adjustable without the use of wrenches or special tools.

All brake clevises, pins, connections and threaded joints must be subjected to

a rust-proofing process on their wearing surfaces.

The design must be such that the application of rear wheel brakes is not affected by relative movement between the frame and the axle.

37. *Gasoline System:* The gasoline tank must be made of drawn sheet steel with welded joints and thoroughly tinned inside and out. Soldered joints will not be acceptable.

Interchangeable Gasoline Tanks

Gasoline tanks must be of 30 gal. capacity and be interchangeable, as per drawing.

Tanks must be fitted with partitions to give two 5-gal. reserve compartments, and must be equipped with a two-way cock for the reserve compartments, combined with a shut-off outlet.

Gasoline tank must be located inside seat body, and mounting devices must be attached to seat body by means of bolts.

Pressure-feed of the gasoline is required, pressure to be supplied by engine driven pump arranged to maintain from 2 to 3 lb. pressure. An auxiliary fuel hand-pump is to be furnished, mounted on the dash. (Many opinions wanted on this.)

The fuel pipe from the tank to the carbureter is to be not less than ⅜ in. outside diameter, and all fuel and pressure pipes are to be properly clipped at suitable intervals, to prevent vibration and chafing.

All fuel and pressure piping is to be of copper, thoroughly annealed.

All fuel and pressure pipe connections are to be S. A. E. standard fittings.

38. *Driver's Seat:* Dimensions of driver's seat shall be in accordance with drawing.

The seat cushion must be covered with genuine leather and be fitted with suitable cushion springs.

Arm rests and seat back must be covered with genuine leather and padded with genuine hair.

The distance between the back of the dash and front of the seat cushion on all trucks must be 25 in.

39. *Dash and Floor Boards:* Dash and floor boards must be approximately the same overall width as seat body.

40. *Driver's Top:* Cape or buggy type of top must be furnished, as per drawing, and covered with first-class 12 oz. water-proof canvas.

A suitable boot or storm apron must be furnished, made of 12 oz. water-proof canvas.

Road Sprags Required

41. *Sprags:* Road sprags must be fitted. These sprags must be of the triangular type and fitted with restraining chains and lifting device, as per drawing.

42. *Towing Hooks:* Towing hooks as shown on drawing, must be attached by rivets or bolts to all four corners of the frame.

43. *Body Holding-Down Devices:* Chassis design must be such that body holding-down devices, as shown on drawing, can be used.

44. *Paint:* Chassis shall be supplied painted with three coats of lead and oil, olive drab color, of the following composition:

6 lb. white lead ground in linseed oil.
1 lb. raw umber.
1 pt. turpentine.
½ pt. Japan drier.
1 qt. linseed oil.

Spare Parts

45. *Spare Parts:* The following spare parts must be furnished with each truck:

4 spark plugs with gaskets.
12 extra sparkplug gaskets.
3 exhaust valves.
3 valve springs.
2 fan belts.
1 assortment of cotter pins, containing not less than 1 doz. of each size used on truck.
1 assortment of lock washers containing 1 doz. washers of each size used on truck.
1 set of radiator hose clamps.
1 length each of all rubber water hose connections.
1 radiator drain cock.
1 box of plain hexagon nuts, to include not less than six of each size on truck.
1 box of assorted castellated hexagon nuts, to include not less than six of each size on truck.
1 box of valve grinding compound, to contain two grades.
1 roll, 1 ft. by 2 ft., of 1/32 in. thick gasket material.
10 ft. secondary or high tension cable.
5 ft. primary or low tension cable.
1 metal box containing one set of electric light bulbs used.
1 box containing 1 set electric lighting system fuses.

Tool Requirements

46. *Tools:* Each truck must be furnished with the following tool equipment:

1 set of open end wrenches to fit all nuts on truck.
1 magneto wrench.
1 3 in. blade screw driver.
1 6 in. blade screw driver.
1 drop-forged all steel 12 in. adjustable wrench.
1 pair of 8 in. combination pliers.
1 valve lifting tool.
1 6 lb. pinch bar 42 in. long.
1 6 in. bastard file.
1 8 in. flat mill-cut file.
1 combination oil- and grease-gun with special tips to fit wheel hub, universal joints and other points requiring oil or grease in quantities.
1 socket-wrench for carbureter nozzle.
1 4000-lb. capacity jack and handle.
1 5-lb. can of soft cup grease.

47. *Extra Oil and Water Supply:* Each truck shall be equipped with a cylindrical drawn steel welded tank with two compartments, one to carry 2 gal. of engine lubricating oil, and the other to carry 8 gal. of water, as shown on drawing, tank to be thoroughly tinned inside and outside and to be fitted with two faucets having ¾ in. through hole, snap spring lock plugs with square ends for use of wrench. No faucet handles to be fitted. This tank must be permanently and rigidly attached to the chassis.

48. *Tests:* Any manufacturer's model of truck designed for military purposes must satisfactorily undergo the following tests, which will be conducted by the War Department. All tests hereinafter specified will be made under a load of 5080 lbs. above the chassis, distributed as specified in paragraph 31.

Ability and Economy

49. *Ability:* On hard roads of 25 to 40 lb. per ton resistance to tractive effort, the fully loaded truck must climb, on high gear, a 5 per cent grade, and on low gear, a 25 per cent grade. Under the same road conditions, the fully loaded truck must be able to start from a standstill in low gear on a 25 per cent grade.

50. *Fuel and Oil Consumption:* On level hard roads of 25 to 40 lb. per ton resistance to tractive effort, the fully loaded truck must average, on straight away running, 9 miles per gal. of gasoline, according to spec. in par. 14, and 200 miles per gal. of engine lubricating oil.

51. *Cooling Ability:* The cooling system must have capacity as follows: At sea level and in an atmospheric temperature of 80 deg. Fahr. and with an initial water temperature of 150 deg. Fahr. the cooling system must be adequate to permit the engine to operate under maximum torque developed at between 600 and 700 r. p. m. in low gear, for a period of thirty minutes before the cooling water reaches the boiling point.

52. *Brake Performance:* Each set of brakes must be powerful enough to slide the rear wheels in either direction on a hard road of 25 to 40 lbs. per ton resistance to tractive effort. At least one set of brakes must be capable of handling the fully loaded truck at a maximum speed of 14 m. p. h. on a descent of 4 miles, averaging 8 per cent grade, without firing the brake linings.

53. *General Road Test:* In addition to the above tests, all military models submitted will be required to undergo a 2000 mile road test, with regular enlisted drivers, carrying a maximum load of 5080 lb. above the chassis, over give and take roads, embodying severe operating conditions.

Early Armored Car Raids Audacious

Cars Taken from Transport Column and Fitted with Steel Plating Constituted First Types Used by British Army in France—Cover Retreats Well—Make Raids at Night

By Granville Pollock

[EDITOR'S NOTE: *For over a year Granville Pollock, of Buffalo, N. Y., was connected with an anti-aircraft corps on the western front in the present war. He had direct charge of the Pierce-Arrow trucks used to carry anti-aircraft guns, as well as other trucks needed for various uses in the corps. Mr. Pollock lived in an atmosphere surcharged with armored car matters and had a good opportunity to observe the practical working out of different types of armored cars, especially as used by the British army.*]

CONSIDERING the rapidity with which events followed one another at the commencement of the Great War, it was only to be expected that many small actions and incidents would occur that, due to the general excitement prevalent almost everywhere at the time, would pass unnoticed, or at least be quickly forgotten.

Yet some of these side issues, so to speak, had a most important influence on the whole military situation, though their full value will in all probability not appear until the end of the war, when the records of both sides may permit of a comparison of values.

In particular does this apply to the events in the northwestern part of Belgium and that part of France known as Flanders, following the fall of Antwerp and up to the Battle of the Yser. For in this short space of time, the actions of a few daring individuals led by an extraordinarily bold and resourceful commander, did more to keep that part of the country and the channel ports clear of the Uhlan patrols and other German detachments than is generally known, or shown in military records; and incidentally, the first occasion on which British forces had used armored cars in Europe.

Fight Way Out of Antwerp

It is usually recalled that Great Britain assisted in the defense of Antwerp with a naval division and an armored train known as "H. M. S. Churchill," and an aero squadron. This squadron was one of the few complete units to get clear of that fortress, the planes flying and the motor cars that comprised the transport fighting their way through the encircling German lines and proceeding west to the port of Dunkerque, where a permanent base was formed, from which they afterward conducted innumerable scouting expeditions and raids into territory more or less occupied by enemy detachments, harassing fairly large units and often totally destroying smaller ones, and numerous patrols.

Armor for Transport Chassis

The cars used in this work were taken from the transport column, and a preference seems to have been given to the Rolls-Royce, as its speed and quietness were two very important features in this class of fighting.

With the assistance of a large shipbuilding yard in Dunkerque, they were fitted with gun mountings to support two or more Lewis or Maxim guns, and a few sections of mild steel sheeting as used in ship work, of about 10 mm. thickness, were bolted over a few places where protection was most essential, such as the radiator, the gas tank and the engine. Even this was but scant protection from a rifle bullet when fired from anything like close range, but it was the best that could be had at that time, though on other occasions they were under point-blank running fire with less protection than this, and managed to get off with few casualties.

For their defense, however, they relied principally on taking the enemy by surprise; a short, sharp engagement, and if unsuccessful, a quick get-away, where their superior speed would soon take them out of range.

Short Night Trips

At first, their movements were limited to short night trips along the roads leading to towns or villages known to have been recently occupied by advance patrols of enemy detachments that were gradually spreading over that part of the country, and when a favorable position was reached—usually a cross road or a wide place in the road with trees or shrubbery that afforded concealment—the cars would be turned around in the direction of home, all lights extinguished, and with engines throttled, all would be in readiness for the first enemy that appeared.

These operations were almost always led by Commander Sampson in person, and never was there any shortage of volunteers to drive the cars or handle the guns, though all realized that the risks were tremendous and the odds never in their favor, as seldom indeed were there less than ten riders in these patrols, and with ditches on each side of the road, a trained man on horseback was decidedly apt to have the advantage in maneuvering.

However, as previously stated, the very audacity of these raids made them a success, and the seriousness with which they were felt by the Germans is best illustrated by the large reward that the Kaiser offered for the head of Commander Sampson, or his capture.

So adroit did these men become in this sort of work that it was not unusual for them to have one or more engagements the same night, while as many as three distinct encounters before sunrise have been recorded. The villagers near their headquarters became accustomed to seeing piles of saddles, rifles, lances and other equipment, and occasionally a string of horses, that was the result of their night's work.

Covering the Retreat

While most of these operations took place in the vicinity of the coast, they made frequent trips far to the south, the most spectacular one being the occupation of the town of Douai, in the face of the advance of Von Kluck's flanking force that was then proceeding north, where Commander Sampson took charge of the few remaining French forces in the town and skillfully conducted their retreat, he, with the cars, remaining behind to the last and barely escaping capture, having to actually fight their way through the advancing line of skirmishers.

It must have made a great picture with these cars tearing

madly along the road, several of them old London omnibus chassis fitted up for the purpose, the enemy's cavalry skirmishers having dismounted and advancing on foot through the woods in an endeavor to head them off, while the flashes of the machine guns and rifles from the cars, showing against the dusk of the evening, gave a spectacular quality to the scene.

On the other hand, it clearly shows that if a few determined men in motor cars, indifferently armed and poorly armored, can operate with such success against field troops for so long a time, what might have been the result had it been possible, in the early part of the war, before trench fighting commenced, to place several brigades of properly organized and trained armored cars, mounting light artillery, to conduct a series of such raids on an enemy's flank.

About the time these cars were armored, the first attempt was made to adapt artillery so as to operate it in connection with them, not by mounting a field piece on the car itself, as they were not built sufficiently strong to permit this, but in replacing the gun carriage with an automobile type of axle, with wire wheels mounting dual pneumatic tires, and the whole towed behind one of the armored cars.

Credit Due Captain Wilding

Credit for this is principally due to Captain Wilding, the well-remembered tennis player, who was so popular in the United States just before the war; and with it, he did excellent work in advanced positions that would have been impossible to reach except for this type of carriage. In fact, in his case, it worked too well, for so annoying did it become to the Germans that they made special efforts to get him, using their heaviest artillery lavishly, which is quite a compliment in its way. They finally succeeded in dropping a coal-box—a 42-cm. shell—onto the top of the dugout in which he and some others had taken shelter when they had first started to shell him.

National's Factory Hospital

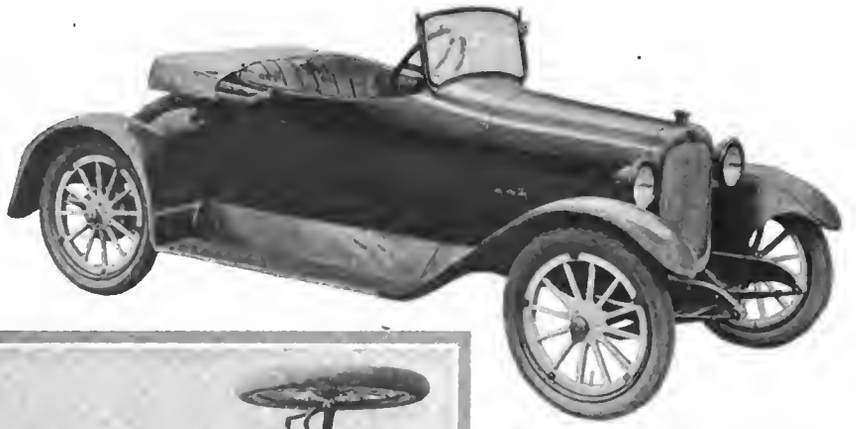
ONE of the most recent developments of the safety first movement which has been inaugurated at the factory of the National Motor Vehicle Co., Indianapolis, Ind., is the installation and equipment of the small but complete hospital shown in the accompanying illustration. This department is located on the second floor of the most central building of the company's plant and is in charge of a trained attendant who is ready at all times to render intelligent relief and first aid service to employees who have been taken ill or injured in an accident.

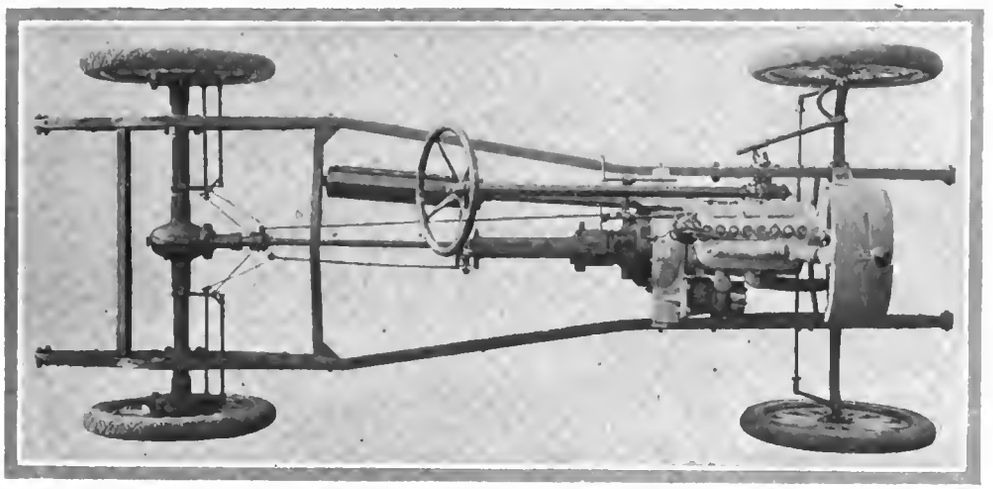
3-Ton F-W-D Truck Hauls 26-Ton Load

The illustration shows a 3-ton truck built by the Four Wheel Drive Auto Co., Clintonville, Wis., hauling a dozen trailers each of which carries 1½ cu. yd. of crushed rock. The truck straddles the narrow-gage track on which the trailers run. According to the Hanlon & Oakes Co., contractors, Sioux City, Ia., fifty teams and trucks were unable to do the work which this truck does at a daily cost of $17. The material is used for the construction of a concrete highway and the truck pulled it up a 5 per cent grade

Low Seats in Maibohm Roadster

$695 Sporting Roadster Is Low Hung with Rakish Lines—Engine High-Speed Four Carefully Balanced





Great simplicity characterizes the chassis lines of the Maibohm, while the body is quite distinctive. Colors are optional and complete equipment is included for $695

THE Maibohm car built by the Maibohm Motors Co., Racine, Wis., has rather an unusual series of characteristics. Briefly the makers have aimed to produce a roadster of low price which gives a combination of speedy performance, smart appearance and comfortable seating. It is a very low-built car with low seats having extra heavy upholstery, so that the passengers sit well within the body despite the rakish exterior. For the convenience of the driver a large range of adjustment is provided on the pedals, and the gearshift and brake levers are bent back so as to come within easy reach.

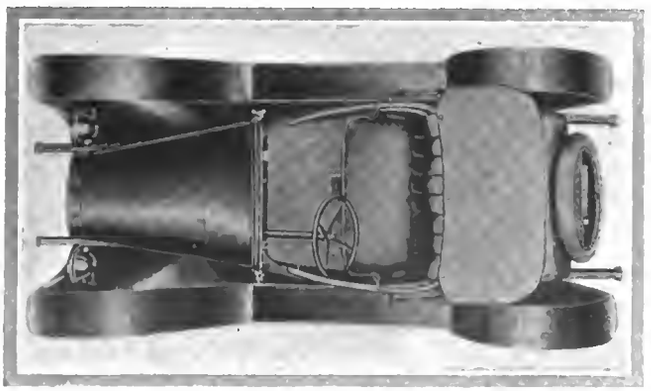
Features Careful Balance

The engine dimensions are 3⅛ in. bore by 4 in. stroke and it is an L-head type having the cylinders and crankcase all in one iron casting. To reduce vibration as much as possible the crankshaft is 2¼ in. diameter and the piston and connecting rod assemblies are carefully balanced and selected in sets of accurately even weight.

Lubrication is cared for by a cam-operated, plunger pump which sends a pressure supply to each of the main bearings and also fills dip troughs under the connecting rods. The oil pan is pressed steel and is provided with a level gage. Rather special pains have been taken to place the oil filler where it is readily accessible, and the illustration of the right side of the engine shows the size and position of the filling cap clearly. This same view also shows the location of the 12-volt Disco motor-generator which is driven by a silent chain from a sprocket mounted on the crankshaft just back of the main bearing at the flywheel end.

The manifolding is unusual, since the exhaust and intake are cared for by a single casting. This insures the supply of adequate heat to the gas and keeps warm the whole of the Zenith carbureter which bolts direct to the manifold. There are no internal passages cored within the cylinder casting of the engine.

For ignition there is an Atwater Kent Unisparker with automatic advance, mounted upon a vertical shaft that is driven from the rear end of the camshaft; this allowing the use of very short ignition leads. Cooling operates on the convection or thermo-syphon system without a pump, and it should be noticed that the tall, narrow radiator is especially well suited to this form of cooling.



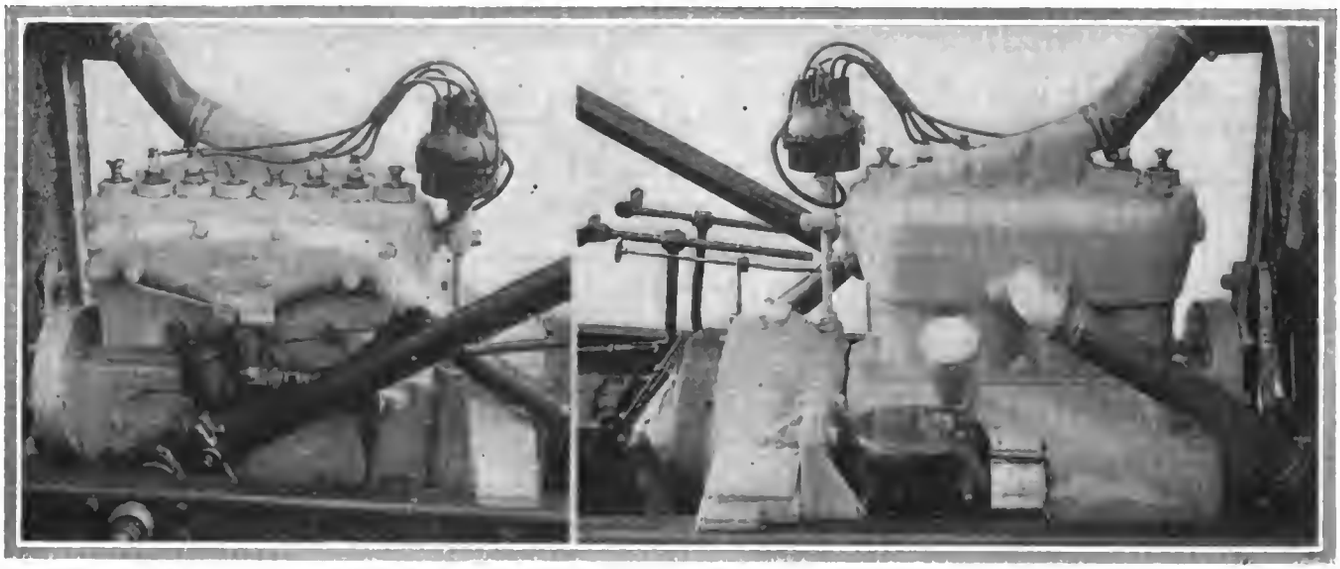
This plan view gives some idea of the seat width

Extension Carries Levers

In unit with the engine is a dry-disk clutch with three plates, and this connects to a three-speed gearset. Naturally the gearset comes just beneath the dashboard, so a special casting is bolted to the rear end of the transmission, stretching back to the seat line. On the end of this casting the gear and brake levers are mounted, the arrangement being shown in the plan view of the chassis.

Hotchkiss Drive Used

There is nothing unconventional about the axles, that at the rear being three-quarter floating. The 46 by 1¾-in. rear springs take both drive and torque. The frame layout is rather unusual, having all four springs mounted beneath it



Left—Shows the combined intake and exhaust manifold used on the Maibohn engine. Right—The electric unit

and none outside. It is 3 in. deep of ⅛-in. stock and is well kicked up over the rear axle. The wheelbase is 105 in. and the tires 30 by 3½-in. on either wood or wire wheels.

That special care was taken in designing the seat has already been mentioned, but there is another particular body feature, this being the provision of an extra large baggage compartment below the rear deck. This baggage case has a large door, closing flush and fitted with a Yale lock. The windshield is mounted with a rake and the one piece top folds down flat so that it accentuates the body lines. Optional colors are obtainable, an almost unheard of thing on a car costing only $695.

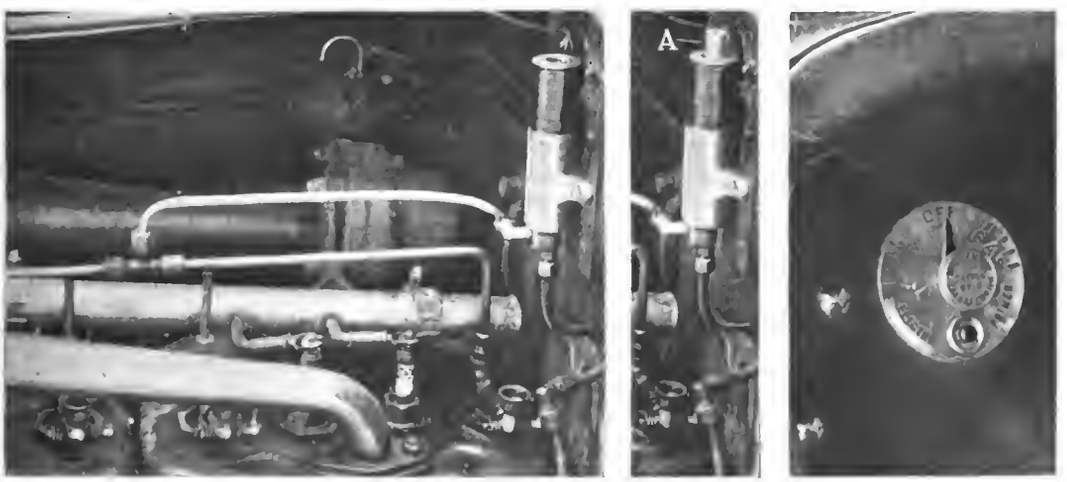
McCormick Primer Is Electrically Operated

THE McCormick Laboratories of Dayton, Ohio, have secured patents on a very accurate device which measures a precise quantity of gasoline which it transfers into a pipe whence it reaches the cylinders successively during the suction stroke.

Beginning at the cylinders there is a small check valve screwed into a valve cap or other convenient place, and these check valves are all joined to a tube running along the cylinder top. The valves open during the suction stroke, but are kept closed as long as there is any pressure within the cylinder. From the middle of the standpipe connecting the check valve a second pipe runs to an electrically-operated pump mounted on the dashboard. This pump has a suction line connected to the main gasoline supply somewhere near the carbureter and the plunger is lifted by a solenoid when current is switched on. On the cowlboard there is a dial with a button controlling a cock on the supply side of the pump and beneath this turn button there is a knob which sends current around the pump solenoid when depressed.

To operate the primer the knurled button is turned to the right and the electric button depressed for an instant. Sending current through the solenoid lifts the plunger, and as soon as the electric button is released the plunger falls, driving gasoline down to the check valves above each cylinder. The starter pedal is then operated and the engine sucks in charges of gas as it revolves. As long as the finger on the cowl dial is kept on the right-hand side the suction will continue to draw gasoline through the little check valves direct from the main supply line, so it is possible to run the engine indefinitely without the carbureter coming into action. As soon, however, as the engine starts it is usually possible to turn off the supply to the primer by bringing the pointer on the cowl to the off position. The same instrument can also be used for supplying additional air. By turning the pointer to the left instead of to the right, the check valves are put in communication with the atmosphere instead of with the gasoline, so that on each suction stroke a small quantity of air is drawn direct into each cylinder.

The device renders it possible to prime directly into the cylinders and eliminates the necessity for soiling the hands by lifting the hood.



Left—McCormick primer which combines an auxiliary air supply. Plunger is in normal position. At A it is at top of suction stroke. Right—Knurled knob and pointer gas and air control. Electric pushbutton is at bottom of dial

The Rostrum

Preventing Valve Stems from Sticking

EDITOR THE AUTOMOBILE:—I have a Chandler 15 and am having trouble with sticking valve stems. Every 1500 to 2000 miles carbon has to be burned out, valves ground and valve stems cleaned and some of them straightened. I am using a high grade medium oil. The repair man says piston rings are not at fault.

Would new valve stems be advisable? Can you suggest a cure? The car has been run 15,000 miles.

Needham, Mass. F. J. R.

—It would be advisable to try relieving the valve stems making them 1/64 of an inch smaller in diameter for a distance of 1¼ in. downward from underneath the head. This should give more room for any carbon accumulation and ought to prevent the valves from sticking.

It might possibly be advisable to try relieving two or three of the valves and see whether this makes those particular valves perform satisfactorily, without relieving all the lot.

If you have to have carbon burned out every 1500 to 2000 miles it is difficult to believe that you are not getting too much oil into the cylinders. Some of the patented rings are very successful in reducing the amount of oil that reaches the cylinder head and I think you would be well advised to try at least one patent ring on each piston.

Wants Data on Hudson Super-Six

Editor THE AUTOMOBILE:—What is the timing of the 1917 Hudson Super-six?

2—What is the lift of the valves and the angle of valve seat?

3—Is the cylinder offset to reduce piston thrust?

4—What is the diameter and length of connecting-rod bearing?

5—What is the timing of the 1916 Marmon?

Trenton, N. J. P. F. H.

—The valve timing of the 1917 Hudson Super-six is as follows: Inlet valve opens 7 deg. after top dead center. Inlet valve closes 42 deg. after lower dead center. Exhaust opens 55 deg. before lower center; exhaust closes 8 deg. after top center.

2—The lift of the inlet valve is 0.3125 in.; the lift of the exhaust valve is 0.3250 in. and the angle of the valve seat is 45 deg.

3—The cylinder is not offset to reduce piston thrust.

4—The diameter of the lower end of connecting-rod bearing is 2.250 in. and its length is 1.989 in.

5—The timing of the 1916 Marmon is as follows: Exhaust closes 12 deg. past top center; inlet opens 19 deg. past top center; exhaust opens 45 deg. before bottom center; intake closes 35 deg. past bottom center.

Gear Ratio on Packard Twin Six

Editor THE AUTOMOBILE:—Kindly furnish me with gear ratio and firing order of the Packard twin six.

Des Moines, Iowa. J. D. E.

—The standard gear ratio of the Packard twin six in high is 4.36 to 1. The firing order in each block is 1, 4, 2, 6, 3, 5, the impulses alternating between the two cylinder blocks. Numbering the cylinders in succession, beginning with number one at the front of each block, the firing order would be 1R, 6L, 4R, 3L, 2R, 5L, 6R, 1L, 3R, 4L, 5R, 2L, the R and L designating the right and left cylinder blocks.

Racing Compressions Are Variable

Editor THE AUTOMOBILE:—What compression is used in the Peugeot, Delage, Duesenberg, Mercer and Stutz racing cars? Please give compression for both 1914 and 1915 Stutz cars.

2—What compression is used in the Packard, Cadillac, Hudson, Franklin and Biddle stock cars?

3—I have seen the statement that for a given sized combustion chamber the compression increases as the motor speed increases. Will you kindly explain this?

Riverton, N. J. R. R. W.

—The compressions used in the racing cars you mention are not available. As a matter of fact, the best compression for racing is usually found by trial and it is liable to vary from time to time. The normal compression for a racing car is about 90 lb. gage.

2—The compression used in the cars you mention is as follows:

Packard—Between 75 and 80 lb.
Cadillac—85 lb.
Hudson—Between 75 and 85 lb. at 100 r.p.m.
Franklin—About 70 lb.
Biddle—70 lb.

3—You have this the wrong way around. The gage compression will be greatest when the engine is running slowly because then the piston is able to draw in a full charge through the valve. When the engine is running fast the wire-drawing action of the valve cuts down the total volume of the charge and the compression is correspondingly reduced. With most engines there is one speed depending upon the valve timing at which maximum compression is registered.

Revamping a 1910 Velie for Speed

Editor THE AUTOMOBILE:—I have read with interest your answer in the Aug. 31 issue of THE AUTOMOBILE to R. W., who is rebuilding a Haynes model T for speed.

It happens that I am the proud owner of a 1910 model four-cylinder Velie 4½ by 5¼. Owing to the fact that No. 4 cylinder has become scored decreasing the power output of that cylinder so that on a hard pull the uneven flow of power is noticeable, I am figuring on having all cylinders bored out and new pistons made so that even amount of power will be obtained from each cylinder. I am not an expert mechanic or automobile engineer, and so probably do not understand all that might be implied from your answer to R. W., but it does seem to me that with this engine working with gas-tight cylinders as it should when rebored and fitted with new pistons and rings (hot air connection to carbureter) that I should get results from it to compare favorably with an engine of 1916 design. Of course I know that 1916 engines are designed with smaller bore, and designed to run at much higher number of revolutions per minute, and are geared for

higher number of revolutions in comparison with car speed, but it seems to me that I should get as much efficiency out of this 1910 engine as I would from a 1916 engine of the same volumetric capacity per rear wheel revolution at speeds of from 10 to 30 m.p.h. Understand, I do not care for high speed performance from this engine as I am satisfied with ordinary touring speeds.

Would it be advisable to crown the new pistons at all? I notice the old pistons are flat. The cylinder heads are integral with the cylinders, and presume they could easily stand the higher compression; however, if this would result in higher explosive pressures, the crankshaft bearings might not be designed to take care of that and I believe that the engine would not run as smoothly at low speeds.

Is there anything that you would advise in connection with reboring and fitting new pistons to obtain more satisfactory service from this engine?

Buffalo, N. Y. L. S.

—You would probably get very good results by boring out cylinders and having new pistons made as you suggest. It would not, however, be wise to crown the pistons, as you will have trouble with pre-ignition and rapid carbon formation if you raise the compression. You could get new pistons partly finished from the Velie Motor Vehicle Co., Inc., Moline, Ill., and your local repairman could finish these to the exact size to suit the rebored cylinders.

While rebuilding the engine make sure that the valve seats have not been ground down so that the valve head sits in a little pocket. It might be advisable to have a light cut taken on each valve seat. See also that the valve stems are a good fit in the guides and not worn, particularly the inlet valve stems. If these wear too small air is sucked up and this disturbs the proper functioning of the carbureter.

While the engine is torn down examine the oil pump carefully and if the gears are worn on the sides, so that they are not a close fit sideways in the case, the latter should be faced down so that the pump cover will be brought closer to the gears. This will increase the amount of oil pumped.

Changing Overland 69 Oiling Inadvisable

Editor THE AUTOMOBILE:—The new oiling systems are giving so many more miles per gallon of oil on practically the same make of engines, could the old mechanical oilers, such as is on Overland 69-T 1913 cars be adjusted to give more miles per gallon of oil without danger of ruining the engine? The new oiling systems are splash systems in one sense of the word and the old mechanical systems merely feed oil into the crankcase, which in turn is splashed on to the cylinder walls, so what is the difference?

2—Would you advise putting a new carbureter on such cars as 1913 model mentioned above, that is, would a new carbureter use less gas per mile than the old one that came out of the car?

3—Can you suggest any other changes that would likely show a saving in gas?

4—What firms make an inclosed body to fit this car?

5—From Greenville, S. C., to Jacksonville, Fla., which is the best route, via Atlanta, Macon, Valdosta, or via Columbia, Augusta, Savannah, and about what is the mileage each way?

Inman, S. C. C. G. F.

—The model 69 cars were all equipped with a mechanical force feed oiler with lines directed to the cylinders, timing gears and the rear crankshaft bearing, the intention being to lubricate the above-mentioned parts, while, of course, the connecting-rods, wristpins and main crankshaft bearings were all lubricated in the usual way by splash. It is very true that by making certain adjustments to the oiler it can be adjusted so as to keep a sufficient quantity of oil in the motor oil base to properly lubricate the motor. However, this would not be advisable inasmuch as the oil directed to the cylinders would no doubt cause excessive accumulation of carbon, and consequent fouling of the spark plugs at occasional intervals.

Thus, it would probably not be advisable to make any changes in the lubricating system. If the engine is properly lubricated and in good condition, adjustments should be readily made that would not require over 1 gal. of oil for each 350 to 400 miles of car running. However, if the car has seen constant service since the year 1913, no doubt parts of the lubricator are worn, and this naturally decreases the oil mileage.

2—Probably you could obtain better mileage with a new carbureter. You would be best advised to take this matter up with the maker of the carbureter now fitted to the car who will know whether one of his later models will give you better results.

3—Only that you take care and see the transmission and wheel bearings are properly fitted and lubricated so that there is no unnecessary friction.

4—The manufacturers of the chassis have no special closed body which would suit you and your best plan would be to inquire of your local dealer. It is, however, doubtful whether it would be worth while to have a closed body built for a 1913 car as it might cost as much as buying a new car with a closed stock body.

5—The best way from Greenville to Jacksonville is as follows: To Athens, 102 miles; to Macon, 97; to Waycross 174; to Jacksonville 81 miles, making a total of 454 miles.

No Formula for Dynamometer Power

Editor THE AUTOMOBILE:—Kindly publish complete formula for calculating the horsepower from a fan dynamometer and an example of its application.

Detroit, Mich. W. L.

—There is no formula which can be relied upon for calculating the horsepower of a fan dynamometer. The reason is that as the fan's speed increases it begins to beat out a hollow in the air and the resistance, therefore, drops below what it would be theoretically. This effect is known as cavitation. It is similar to the action of a gear cutting out a hollow in soft grease. The only way in which the power absorbed by any given fan can be ascertained is by driving it at different speeds with an electric dynamometer and actually measuring the horsepower absorbed.

Removing Tar from Car Body

Editor THE AUTOMOBILE:—What is the best method of removing tar or Tarvia from my car? I recently had to drive twice a day for 2 weeks over a road freshly covered with it. The chassis is absolutely covered and the body not much better.

Westmount, P. Q., Canada. A. E. J.

—Soap and water used promptly will generally remove tar or Tarvia. It can also be softened by the application of butter or oleomargarine without damage to the varnish.

Another good solvent is cocoa butter, which is used in the theatrical profession for removing grease paint. This can be purchased in some drug stores and is a harmless solvent for all kinds of oil and grease as well as tar.

Wants Differential and Transmission Assembly

Editor THE AUTOMOBILE:—Are there any concerns making a transmission and differential assembly that is interchangeable with the one used on a 1912 Flanders 20 model? If so, please give list.

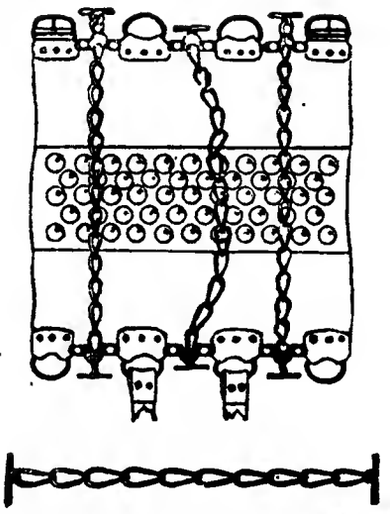
Burlington, Vt. H. L. W.

—THE AUTOMOBILE has no record of any concern making such an assembly as you require.

ACCESSORIES

Anti-Skid Shoe

THIS shoe is made of two-ply leather reinforced up the middle with an extra strip which is studded with rivets having heads about ⅛ in. thick. The chains that cross the reinforced part of the shoe, as shown in the accompanying illustration, are made of heavy wire of high tensile strength. The shoe can be used as a blow-out patch; it acts as a preventive of blow-outs when strapped to the weakest spot on the tire; it gives traction when the wheels are stuck in the mud and the manufacturer states that it cannot injure the tire. The shoe is held on the tire by 1-in. chrome leather straps lacing through rings and the strap and buckle adjustments render it possible to draw up the shoe very tightly. Since the straps are attached to the boot the shoe cannot be lost. When the shoe is used for a blow-out patch the anti-skid chains are easily withdrawn by slipping a small ring through the brace and their replacement is just as simple. With non-skid chains the 3 by 3½-in. size sells for $2.50; 4 by 4½-in., $2.75; and 5 by 5½-in., $3. Chains, including end rings, list at 25 cents for set of three in the 3 by 3½-in. size, 35 cents in the 4 by 4½-in., and 45 cents per set in 5 by 5½.—Auto Anti-Skid Shoe Mfg. Co., 31 Nassau Street, New York City.



Above—Anti-Skid shoe designed to act as a blow-out patch, to give traction and to prevent skidding. Below—One of the chains, which are easily detached

Sebring Tire

This seven-ply tire is impregnated with pure gum rubber and has a non-skid tread. The gum friction coat is built between the fabric and the tread and is said to promote easy riding and to require a low tractive effort. Straight side tires are offered and are applicable to any type of rim. The tires are retained on the rim by nineteen strands of piano wire. The Ford type tire is the only exception to this form of rim and is a regular clincher. —Sebring Tire and Rubber Co., Sebring, Ohio.

Section of Sebring Efficiency tire tread, showing wires that retain the tire on the rim

Johnson's Carbon Remover

This liquid carbon remover is easy to use, the spark plugs being removed and four tablespoonfuls poured into each cylinder. After 2 or 3 hours, or preferably after leaving the liquid standing over night, the engine is started, blowing the loosened carbon out through the exhaust. The remover softens the carbon and detaches it from the cylinder walls, etc., without in any way harming the engine. It sells for 50 cents per half pint, 85 cents per pint and $1.50 per quart.

Johnson's Blac-Lac is a dressing for tops, leather cushions, side curtains, tire covers and trunks. It is also useful for touching up other parts of the car, one coat being said to give a rich black finish to the parts mentioned, or to fenders, rims, running boards, radiators, lamps, etc. It is applied with a brush, being in liquid form, and is said to act as a preservative of leather, etc. It does not come off on the hands or clothing, according to the manufacturer, who also produces Johnson's Prepared Wax and Johnson's Cleaner for car bodies. The Blac-Lac sells for 40 cents per half pint, 65 cents per pint and $1.10 per quart.—S. C. Johnson & Son, Racine, Wis.

Trump Jack

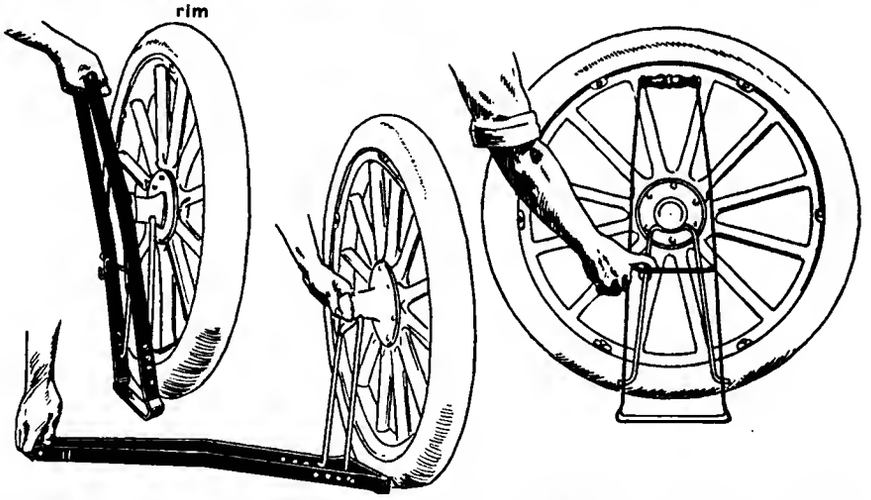
The car may be readily lifted from the floor by means of Trump jacks. A compound lever caught beneath the hub lifts the wheel free from the floor and locks it in the raised position. The strain on the tires is thus relieved and the tires are removed from contact with an oily floor. The height of the jacks may be adjusted and it is said that each jack will support 5000 lb. Price, per set of four, $5.—Trump Products Co., Garland Bldg., Chicago, Ill.

Lewis Pneumatic Grease Gun

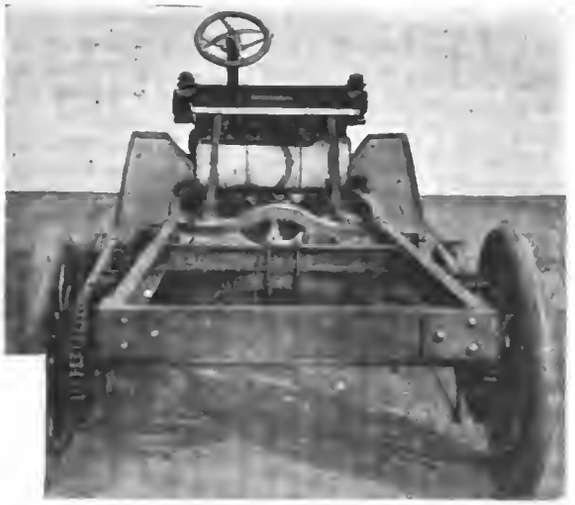
This gun is designed to handle lubricants of all consistencies from the hardest cup grease to the hardest cylinder oil, and may be used for filling or emptying gear boxes, differentials, etc. It is double acting and self filling. It is 2 in. in diameter and 18 in. long and is operated by compressed air at pressures of 50 lb. or more. There are two nozzles, one for fluids and the other for heavy greases. Price, $10.—Lewis Pneumatic Grease Gun, Chicago, Ill.

U-Can-C Rain Shield

The U-can-C rain shield placed on the market last season has been improved by the use of somewhat larger vacuum cups made from rubber compound. Each cup is provided with a shank that facil-



Trump jacks are useful as tire savers since they lift the car from the floor, thus not only relieving the tires of its weight but also keeping the rubber from contact with the oil on the floor, which is frequently a cause of deterioration of the rubber



Franklin Convertor for Ford chassis

itates its application and removal from the windshield. When in place before the driver's seat, the shield serves to keep the glass free of moisture and water by the aid of a rubber sealing strip. The use of the larger cups, says the manufacturer, causes cups to adhere rigidly even in a strong wind, or when applied to a dry glass. They may be rolled up and packed away in a tube 3 by 11 in. They are made for all cars. Amber shields sell at $2 each; clear shields at $1.50.—Frey Mfg. Co., 1326 Michigan Avenue, Chicago, Ill.

Apco Ford Breather Pipe

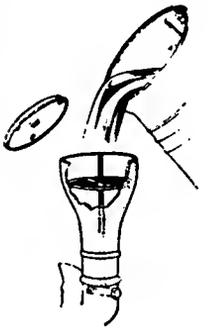
This breather pipe for the crankcase of Ford cars is an upright pipe, containing a fine screen, is secured to the oil intake by a hooked bolt that fastens around the timer retaining bolt. The installation is said to make the renewing of the oil supply an easy matter and to prevent the oil from spraying from the crankcase. The cover is easily removed or replaced, and the screen prevents the entrance of foreign elements. Price, 50 cents.—Auto Parts Co., Providence, R. I.

Glare-Off Lights

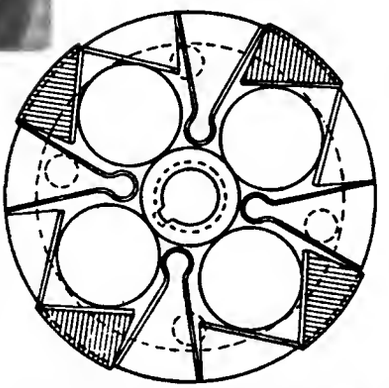
An ornamental metal shield covers the upper portion of the headlight lens and causing the light rays to be concentrated on the road. The ascending rays are reflected by the polished surface of the shield, thrown back onto the reflector of the lamp and thence onto the road in a manner that does not blind the oncoming driver. The face of the shield carries either a club monogram or any ornamental design desired. Price, $1 per pair.—Glare-Off Co., 1777 Broadway, New York City.

Automatic Spark Advance

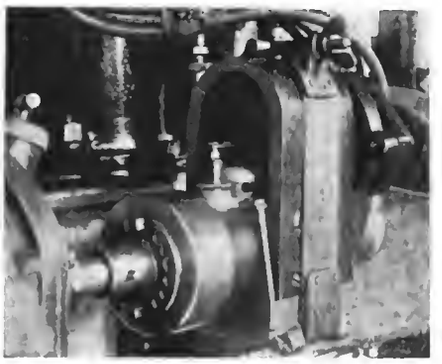
The spark is automatically advanced by the centrifugal action of four balls, driving and driven members of the coupling being constructed so that there are four V-shaped compartments in each one of which there is a ball. One side of the compartment is part of the driving member, and the other part of the driven. As the speed increases the centrifugal force throws the balls outward, and forces the sides of the V's apart, thus advancing the spark. It is said that it may be installed in place of the usual coupling between the pump and magneto and will fit any standard magneto.—Automatic Spark Advance Co., Monadnock Bldg., San Francisco, Cal.



Apco breather pipe for Ford cars, designed to facilitate renewal of the oil supply in the crankcase



Cross section of the governor on the Automatic Spark Advance. The centrifugal force of the balls in the V-slots advances the spark



Automatic Spark Advance as attached to a magneto

Franklin Convertor for Ford

Converting the Ford into a 1-ton truck without damage to the chassis, permitting it to be converted back again into a passenger car, is the function of this construction. The rear axle becomes a jackshaft and is bolted onto the new channel frame by means of a special casting. A special bell-sprocket that telescopes over the brake drum carries the chain that drives the truck wheels, and permits the use of standard gauge. The change requires only the removal of the rear wheels, rear spring and radius rods and the bolting on of the convertor. It is claimed that no skilled labor or special tools are required to make the change. Price, model A2, $345; model A3, with motor governor and jackshaft brake, $400.—Franklin 2-Way Convertor Co., Herald Bldg., Chicago, Ill.

Oxy-Ignitor Spark Plug

The Oxy-Ignitor plug replaces the O-G, the patent papers and exclusive manufacturing rights of the latter having been purchased by the maker of the new plug. Minor improvements have been made and the plug has been subjected to severe tests. The porcelain is inclosed by the shell and the central electrode terminates in four points, one or all sparking at the same time. The plug may be taken apart easily and all parts are replaceable. Each plug carries a guarantee to be sootless and to last during the life of the engine. —Oxygenerator Co., 1919 South Michigan Avenue, Chicago, Ill.

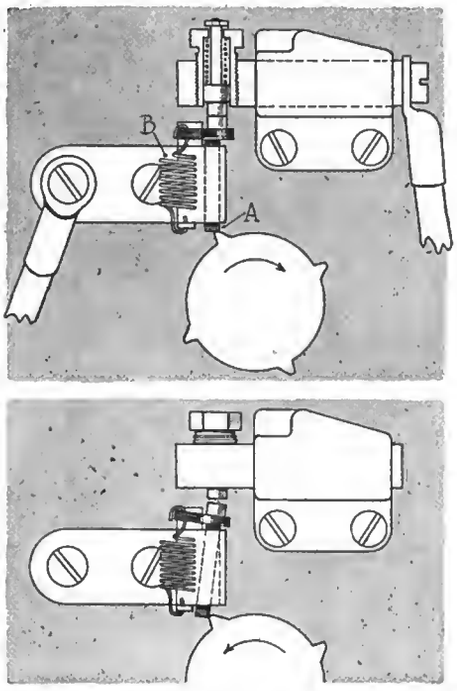
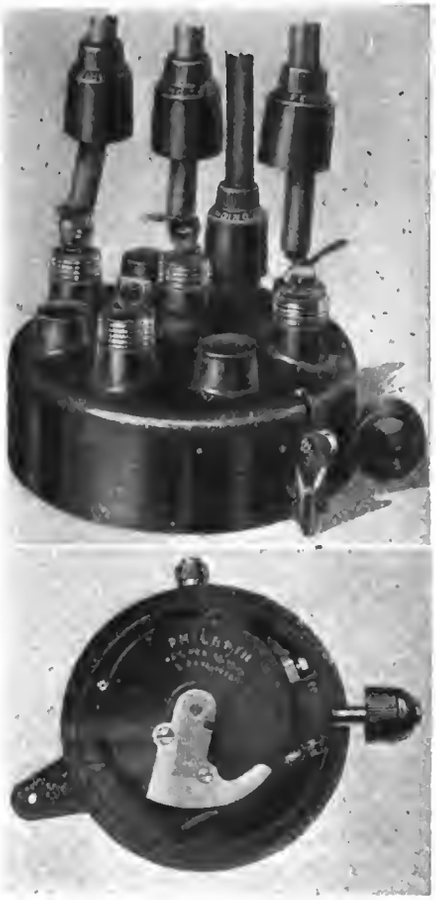
Philbrin Battery Ignition

New Duplex System Gives Alternative Forms of Spark Production—Includes Novel High-Speed Breaker and Follow-Up Spark System



Full size sketch of Philbrin cam and contact action. Upper shows the cam lifting the contacts and closing the circuit. Lower indicates the way the trigger folds back should the cam turn around in the wrong direction



Above—Twelve cylinder unit with coil mounted on the side. Right — The construction of the distributer terminals which give a very secure grip on the wires and view of the long sector suitable for a four-cylinder distributer

PRODUCED by a man who has been in the battery ignition business for a good many years, the Philbrin duplex battery ignition has many unique points. It is made by the Philips-Brinton Co., Kennett Square, Pa., who are just ready to supply in quantities. As its name implies it is a system including two alternative methods of producing the spark, and either of these methods can be used with storage battery or dry cells. The two methods of spark production are called, by the makers, the main system and the secondary system, and as they operate on quite different principles they can best be considered separately.

The distinctive feature of the main system is the constructive detail of the contact breaker. This is small, very strong, gives a square contact between the points and a very quick break which is claimed to have less lag than any other type. In the sketch above the principal parts of the contact breaker are shown on a magnified scale. The upper contact is set in an adjustable socket backed by a strong coil spring. The lower contract is secured to the end of a hardened steel trigger *A* which can be lifted from beneath by the cam point. To follow the action imagine the cam rotating clockwise. The point of the cam will catch the foot of the trigger and lift it till the points are in contact. The spring above the upper point determines the firmness of the contact obtained.

Lag Almost Eliminated

As soon as the tip of the cam reaches the edge of the trigger, all support is removed and the small coil spring *B* causes the trigger to fly back with practically no lag whatever the speed. This quickness is due to the very light weight of the trigger and to the rapidity of action obtainable from a coil spring.

Now, it is easy to make a rapid action cam with a square drop like this, but precaution has to be taken to prevent the trigger from being broken off should the engine reverse its proper direction of rotation. To guard against this possibility of damage, the trigger slides in a groove as seen in the sketch, but this groove is open behind the trigger which is held in its working position by the spring. Thus, if the direction of rotation is reversed, the trigger merely moves back out of the way as if it were hinged at the top.

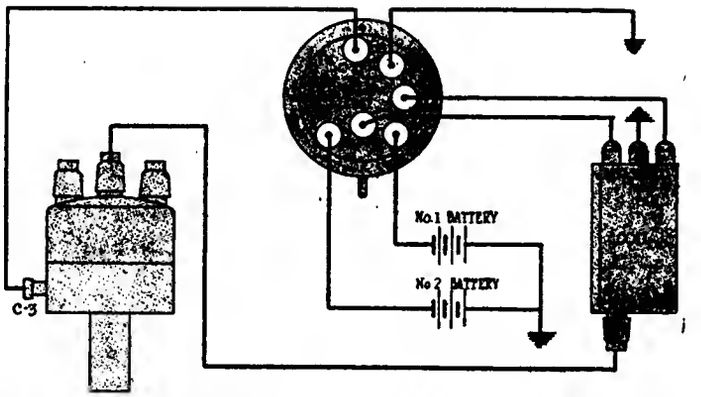
The cam points are so designed that they give a duration of contact equivalent to 3½ deg. of movement which is sufficient to permit the current to saturate the condenser at speeds of the cam sufficient to fire a 12-cylinder engine at 5000 r.p.m. There is only one adjustment, this being the closeness of the contact points which should be about 25-30/1000 in., apart when broken. When the points wear down the need for adjustment will become apparent through the engine refusing to run at maximum speed; when this is noticed a fraction of a turn of the nut back of the upper contact will restore the original speed range.

The condenser for the main ignition is contained within the breaker box, and the coil is either combined with the distributer unit or is separate. The switch selects either storage battery or dry cells in the usual way.

For spark advance the Philbrin has no automatic mechanism this being said to be needless because of the absence of lag in the breaker. A lever is provided for hand advance and is made in two forms; one moves the whole distributer and another moves the cam without affecting the external parts.

In connection with this "main" system there is a distrib-

uter which is also part of the secondary system. It is mounted above the breaker box and is of the non-contacting type, where the high tension spark leaps a small air gap. Inside the distributer head are a number of brass studs corresponding to the number of cylinders, and above the breaker cam there is a Bakelite disk carrying a brass sector which conveys the high tension discharge to each of the spark piug leads in turn. It will be noticed that this sector is very long, being only a little shorter than the circular distance between any two of the fixed studs in the distributer head, this meaning that the front edge of the sector is within 7/32 in. of the stud ahead of it while its hind end is still level with the edge of the stud behind. The reason for this great length of sector is made plain by the description of the secondary system.



Wiring diagram of Philbrin duplex ignition system

No Breaker for Secondary

The secondary system uses no part of the breaker mechanism. Within the switch assembly that attaches to the cowl board, is a special form of vibrator, consuming little current and operating at a vibratory speed of from four to five times that of the old-fashioned coil vibrator. There is a very peculiar thing in connection with this vibrator, this being that it requires no adjustment, in fact the manufacturers disclaim all guarantee if the adjustment is altered within the lift of the contact points. The latter are large, and will wear a very long time, and it is stated that the action is not affected in any way by such wear as can occur up to the very last limit.

Two Switch Controls

Looking at the outside of the switch box it wili be seen that there are two controls. The lever gives the "off" when in the middle position and can be turned right and left to pick up the storage battery or the dry cells. Above it and to the left is a knob moving on a ratchet. This gives a series of positions marked *M* and *S* meaning main and secondary ignition. When the pointer is opposite any of the *M* marks the breaker is working and the engine being fired on the single spark system, but when the pointer shows an *S*, it means that the contact breaker is cut out altogether and a continuous current is flowing through the vibrator all the time the switch is on.

Continuous Stream of Sparks

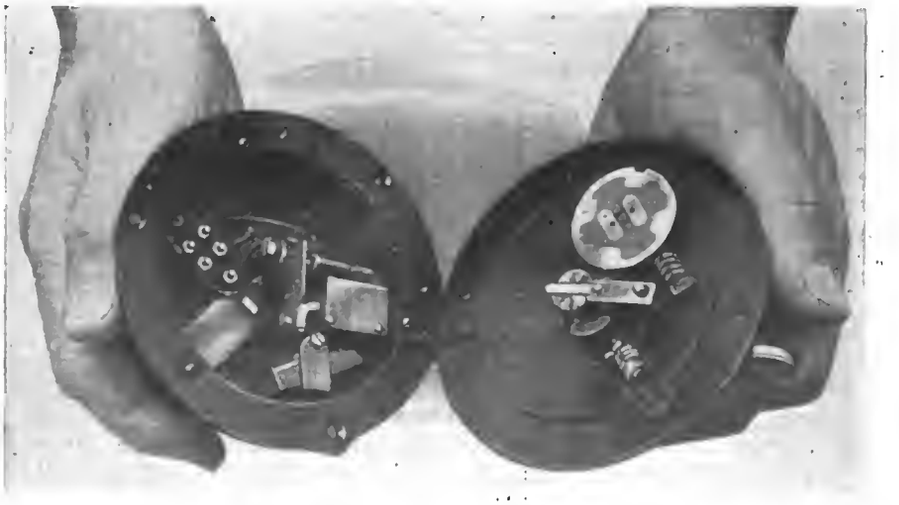
The vibrator is in circuit with the primary of the coii, so a steady stream of sparks is being sent to the distributer, and this is the reason for the long distributer sector. As the distributer turns it will continue to supply sparks to any one of the plugs during the whole time the sector takes to pass the stud in the distributer head. As the piston descends on the firing stroke the resistance at the spark plug points drops, so when the front end of the sector is approaching the next stud, there is no risk of a long thin spark jumping out ahead of the sector, the next spark plug will not get a spark at all till the sector is close enough to insure a good fat discharge.

Prevents Fouling of Plug Points

Naturaliy such a sort of ignition is very effective, particularly if the carbureter is not working well or if the engine is very cold, and it is also claimed that the continuous spark prevents oil from collecting on the plug points. The discharge is said not to injure the points because its intensity is never great enough to do them any harm, increased speed has no effect on the nature of the spark; there is no flame produced. As to the current consumed this is about one ampere, or similar in amount to that taken by a cowl board lamp bulb, much less than that consumed by a headlamp of ordinary size and power.

Current Reversed Constantly

It will be seen in the view of the switch cover that there are a series of *M* and *S* positions controlled by the ratchet knob. Their purpose is to reverse the direction of the current flow at each click of the ratchet and so equalize the wear on the contact points of both main and secondary systems. In the center of the main switch lever there is a lock operated by a key, and the cover of the switch cannot be removed even by taking out the screws as long as the lever is locked in the off position.



Left—Switch cover as it appears on cowiboard. Right—inside of switch showing the vibrator employed for the secondary ignition and the details of the selecting and reversing switch which gives either main or secondary ignition and reversee the direction of the current with each click of the ratchet

Cleveland—Rising City in the Industry

Part II

Over Eighty Manufacturers of Parts Produce in Cleveland Factories 70 to 75 Per Cent of the Automobile Parts Used in the Middle West

CLEVELAND, O., Oct. 3—According to the 1914 government census, Cleveland leads all other cities in the production of automobile parts which are assembled in other cities into complete cars. At present over eighty manufacturers of automobile parts are located in Cleveland, and the Cleveland Chamber of Commerce, which has been very active of late in inducing automobile industries to locate in Cleveland, has estimated that from 70 to 75 per cent of the automobile parts used in the Middle West manufacturing section are manufactured in the Cleveland district. These include drop forgings, sheet aluminum, sheet steel, frames, bearings, leather, paints, varnishes, etc. To these might be added various accessories, such as batteries, spark plugs, lamps, etc.

In its new campaign to increase its automobile manufacturing position, Cleveland, through its Chamber of Commerce, has announced that it does not covet Detroit's leadership as being the first automobile manufacturing city, but rather has in mind a much wider diversity of industries. The aim is to make the Cleveland district a unit within itself, capable of supplying its own needs in a manufacturing way, without being dependent on other cities.

To Attract Factories

With this end in view, the Chamber of Commerce is working to attract factories producing all varieties of automobile parts, and is at present looking for manufacturers of bodies, sheet metal parts, and additional frame makers. All of these are produced in Cleveland, but greater output is required.

In its work of securing factories for the city, the local chamber has never offered and declares it never will offer, any material inducements to industries seeking a location in Cleveland. There has been formed in the city, however, a Cleveland Industrial Development Co., with an initial capital of $500,000, which interests itself in the financing of new factories, such as automobiles, parts and accessories.

Cleveland has many arguments which are advanced as potential reasons for automobile parts, and accessory factories locating there. It is a large primary and secondary steel city. Iron, ore, and coal can be assembled here cheaper than in any other district in the North. It is a good city for working men, more than 25 per cent of Cleveland's present inhabitants owning their own homes. There is a 3-cent carfare covering the entire city.

A Large Railroad Center

This city offers exceptional shipping facilities in that over 350,000 sq. miles of country are served directly by the railroads radiating from this zone. This is practically 10 per cent of the total area of the U. S. A. Seven trunk lines enter the city, these including New York Central, Pennsylvania, Big Four, Nickel Plate, Erie, B. & O. and Wheeling & Lake Erie. The city is immediately served by the Cleveland Short Line Railway, a part of the New York Central. This belt line is 19 miles long and connects all railroads entering the city. There are thirty-nine freight stations within the city's switching limits and twenty-two passenger stations. In addition there are six electric interurban systems radiating from the city through Northern Ohio. Most of these carry freight.

Last week several of the Cleveland factories which are engaged in the automobile industry were referred to with the object of showing their growth during the past season. There are many others in the city, some of which refuse to make public figures showing the growth of the industry, and others from whom it has not been possible to get the information to date.

Columbia Axle Expands

The Columbia Axle Co., established 3 years ago, has increased its business four-fold during the past year, and now has capacity for 75,000 axles per year. Over 450 men are employed, and 50,000 sq. ft. of floor space used. New additions are planned to add 5000 sq. ft. of floorspace for rough stock and receiving department. These will be ready in 30 days. Besides manufacturing front and rear axles for several passenger car makers this concern manufactures truck axles for several concerns.

Reflex Business Gains 25%

During the past year the Reflex Ignition Co. has increased its business 25 per cent and doubled its manufacturing space. Over $20,000 worth of new machinery has been added for its spark plug manufacture. Its capacity is 3000 plugs per day. The factory has been working overtime 3 hr. per day since July.

Torbensen Boosts Production

The Torbensen Gear & Axle Co. has during tbe year added 60,000 sq. ft. of floorspace to its own manufacturing facilities and is employing 200 men. Over $100,000 worth of new machinery has been installed. In 1915 approximately 1900 Torbensen axles were produced and sold to motor truck manufacturers. By the end of 1916, a total of 11,000 will have been produced and sold. For 1917 the production figure is 25,000. In addition to its own manufacturing facilities the company has had to contract with another Cleveland concern for manufacture of many axles.

Hydraulic Pressed Steel Rushed

The Hydraulic Pressed Steel Co. has increased its business 15 per cent during the past year. In that time it has erected five new buildings as follows: A forge plant 360 by 80 ft.; an automobile frame plant 560 by 80 ft.; a receiving building 120 by 60 ft.; a power plant 80 by 40 ft., and a pump house 160 by 40 ft. Over $400,000 worth of new machinery has been installed. The company now employs 1200 men, has a capacity of 1500 automobile frames per day, and two-thirds of its entire factory has been working at night since 1914. This factory is still another example of the great activity of Cleveland plants that are not much in the public eye so far as automobiles are concerned, but which manufacture many parts entering into cars made in many different cities.

—

Michigan Has 143,550 Cars

LANSING, MICH., Sept. 30—State records show that on Sept. 1, 143,550 automobiles were registered in Michigan, or 25 per cent more during the first 9 months of 1916 than during 12 months in 1915, when the total was 114,845. Of the 143,550 cars there were 10,196 commercial vehicles.

In Wayne County, in which Detroit is located, there are 41,375 of the 143,550 cars, or 10,348 more than were registered in 11 months last year. It is estimated by officials that the total registration for the year will be between 155,000 and 160,000 cars.

Mismanaged Racing

THE finest speedway in the world situated within the greatest city in the world deserves the best management in the world. Judging by the general handling of the Astor Cup race it has got something much nearer the other end of the scale.

During the race a driver on pulling up at the pits complained of spectators standing *on the track* opposite the bleachers. When the winner pulled up at the pits a crowd of thousands swarmed the fences and blocked the pits, spreading out to the boards, where thirteen cars were still running at nearly one hundred miles an hour.

The Vanderbilt Cup race was abandoned because of the deaths it caused, but the danger to spectators on a road course is a tiny trifle compared to their danger on a speedway. Every race manager knows that the public in moments of excitement must be protected against itself, so when the custom of huge crowds is sought huge precautions should be taken. To get enough track guards to police the New York speedway as it should be policed is quite easy. Indianapolis with a far larger crowd to care for has never had any difficulty, though it is much harder to get an adequate staff there than in New York.

Then, again, the drivers who enter an event like last Saturday's have *some* rights. If the management care nothing for the public they ought at least to protect their entrants from the smash up which only good fortune can avoid with spectators on the track. The drivers also have a right to expect that the times will be given out accurately and quickly.

The mismanagement of the Astor Cup race was thorough. Letting the crowd on the track was the biggest sin, but the timing was bad, and even the detail handling of the crowd was poor. In parts of the grandstand the attendants did not know the numbering system and could not show people their seats, and the second gate for pedestrians was not opened till more than an hour after the appointed time.

It is this sort of thing that kills speedways and kills public interest in racing.

The newspapers express wonder at the small size of the crowd, the owners of the track are naturally disappointed that they could not fill the grandstand nor get the patronage of a fifth of the people who could easily see a race on foot.

Tires

WHAT is the biggest item in the cost of motoring? Tires, because they wear out so fast.

American racing, culminating in the Astor Cup, has shown how to multiply tire life by ten. The racing tires which carried nearly every car in the race right through without changing a shoe are not yet tires of commerce, but they soon will be. The racing tire of today is the touring tire of tomorrow; so the time is in sight when tires will become much less troublesome than they are now.

Remembering the tire stops in the races of two years ago it seems incredible that so much improvement could be made in so short a time. Certainly the board speedway is kind to tires, also no doubt the cool air temperature on Astor Cup day was a help, but despite this the tire showing was a marvel.

That the winner could run right through at so high a speed is astonishing, but it would be far less pregnant with meaning were it not for the paucity of trouble on other cars. One example may be luck; a high average all around is proof positive that luck had nothing to do with it. Racing has contributed much to the betterment of the everyday car. The contribution from the American seasons of 1915 and 1916 is one of the most far reaching in its effect that the history of racing can show.

Obtaining Ideals

THE effort of the S. A. E. to prepare an ideal military truck specification is one of the most praiseworthy things the society has ever attempted. No engineer is ever able to build his ideal machine because of all kinds of limitations, but he has usually a very good idea as to what that ideal is. In preparing the military truck specification, the S. A. E. members will be untrammeled. They have not to consider price, nor their factory equipment, nor the ideas of their sales department; nothing troubles them except determining what they really think is *best* for the specially arduous conditions of military service.

Metz Has Balanced Crankshaft

1917 Model Reduced to $545—Engine Parts Lighter—Body Improved

NEW YORK CITY, Oct. 1—The 1917 Metz will have a balanced crankshaft and will sell at $545, f.o.b. factory, a reduction of $55. The reciprocating parts of the engine have also been lightened. Body lines have been improved and a new ventilating hood has been provided with nickel-plated clamps. The new car has metal hood sills. The metal-covered windshield board has all been enameled. The steering column brackets have been improved and an electric dash light has been placed on the instrument board. Pockets have been placed in the tonneau board.

The standard wheel color is vermillion, with an option of white or purple blue. Either wire or artillery wheels may be had. Demountable rims are not furnished as standard equipment. The front guards are made to curve gracefully over the wheels and blend into the body sides by the use of a steel apron that protects the occupants of the car from road and wheel splash.

—

Commerce Enlarges and Adds Model

DETROIT, MICH., Sept. 27—Stockholders of the Commerce Motor Car Co. have sanctioned an increase of the capital stock from $200,000 to $400,000. A 1-ton model has been brought out by the Commerce company and 3000 of these trucks are scheduled to be made during the next 12 months. The chassis with driver's seat will sell at $1,175. In addition to the 1-ton truck there will be made 1800 ¾-ton trucks. The increase in business of the company has made it necessary to enlarge the plant and an addition 60 by 250 ft. is now being built.

—

Cotta Transmission Expanding

ROCKFORD, ILL., Oct. 2—The Cotta Transmission Co. has purchased 100,000 sq. ft. of land, upon which a factory of the monitor type will be erected. The present plant is to be abandoned. The change is made necessary by increased business and the necessity for enlarged quarters. The new plant will be ready Nov. 12 and will have 27,000 sq. ft. of floor space. At present the company is employing 100 men. The new plant will employ twice this number.

—

Agrimotor Will Design Tractors

LA CROSSE, WIS., Oct. 2—The Agrimotor Engineering Co., La Crosse, Wis., has been organized by C. W. Levis, for many years sales manager of the La Crosse Plow Co., to engage in the design of tractors, farm implements and accessory lines. Levis has been elected president and manager of the new concern, which will make a specialty of marketing both patented and unpatented implements or parts and serve as agents for patentees and attorneys. In its agency capacity the company will endeavor to arrange for the manufacture of implements or attachments which have merit. A competent force of engineers, designers and draftsmen has been procured.

—

Chandler Starts New Assembly Building

CLEVELAND, OHIO, Sept. 30—Further expansion in the manufacturing facilities of the Chandler Motor Car Co. is marked by the beginning of construction of one new general assembly building 60 ft. wide, 500 ft. long and four stories high, and the addition of three stories to the 60 by 160 ft. service building erected earlier this season. With the completion of these two new buildings the Chandler company will have on its factory site five manufacturing buildings.

The new buildings will be ready for occupancy in time to help take care of the production of next year's series of Chandler sixes, a contemplated production of 25,000 cars.

The Chandler company also has purchased a large piece of property directly across East 131st Street from the main factory buildings, and on this property will, next spring, erect a building to be devoted exclusively to the handling of export shipments, installation of special foreign equipment, boxing cars ready for delivery to steamships, etc.

The comfort of Chandler employees has been borne in mind by the company in its extended building plans. One floor of the big service building will be devoted to a restaurant. Included also in the plans permitted by the new building is an emergency hospital in which a trained nurse will be on duty during factory hours and in which the company physician will make his headquarters.

—

Michigan Foundry to Be Doubled

ST. JOSEPH, MICH., Sept. 26—The Michigan Malleable Foundry Co. is to be practically doubled. A building, 100 by 300 ft., is now under way and contracts have been let for a further addition, 60 by 80 ft.

—

Rumely To Make All-Steel Tractor

LAPORTE, IND., Oct. 2—The Advance-Rumley Co. is experimenting in the manufacture of an all-steel tractor. Heretofore considerable wood has gone into the construction of tractor bodies. Recently the possibility of manufacturing an all-steel tractor gained headway in the Rumely office.

Belgian Engineers Arrive

Kelecom and Perrier, of Fabrique Nationale, Here to Visit Car Plants

NEW YORK CITY, Sept. 28—Two of the leading engineers, one of Belgium's largest motor car, motorcycle and ammunition factories, arrived in this country this week for the purpose of making manufacturing investigations and doing engineering work here. Both were engineers in Fabrique Nationale, the large factory at Liege which previous to the war manufactured F. N. motor cars, motorcycles, etc. Paul Kelecom was engineer of the motorcycle department of the factory for 12 years, and for 6 years previous was in the automobile industry. Julian Perrier has been connected with the engineering department of the F. N. factory since 1905, in charge of the development of automobile motors and motor car design. For 9 years he has been specially engaged in engineering research and laboratory work.

The F. N. factory was closed on Aug. 3, 1914, and since that date has been practically deserted. Over $1,300,000 worth of machinery has been removed from the factory by the Germans and taken to Germany. The factory is now used as a field repair depot by the Teutons. Previous to the war the F. N. factory was building 1200 automobiles a year and upward of 4000 motorcycles. In addition to this there were a great many small firearms manufactured. Over 4000 men were employed. Since the outbreak of the war Messrs. Kelecom and Perrier have been engaged in the organization of the Belgian military motor transport system. Both gentlemen expect to make a tour of the U. S. A. automobile factories.

Three-Plow Tractor Sells at $500

HAMILTON, OHIO, Oct. 2—J. A. Vail is president of the Vail-Rentschler Tractor Co., which will produce a three-plow machine to sell at $500 to $600. Other officers of the company, which has been capitalized at $100,000, are: Secretary, Sam S. Vail; vice-president, C. B. Wing; chief engineer, E. O. Powers; field agent, L. F. Kerner. J. A. Vail, E. O. Powers and L. F. Kerner were connected with the Fairbanks-Morse Co.

—

Kerosene Carbureter to Be Made in Des Moines

DES MOINES, IOWA, Sept. 30—A carbureter attachment which can be fitted to any car and which will permit the use of kerosene will be manufactured by a Des Moines company, capitalized at

$250,000, which has applied to the Secretary of State for a charter and which will be known as the Trotter Kerosene Carbureter Co. Directors of the company are: H. S. Butler, vice-president of the Iowa National Bank; D. F. Witter, vice-president of the Iowa Loan & Trust Co.; John Gilchrist, George Phillips, George Trotter, G. A. Huffman, and W. Hartley.

It is claimed for the device that it can be used for either gasoline or kerosene, and that it will increase the gasoline mileage by one-half, while securing from kerosene the same mileage as for gasoline without the attachment. The factory is to be erected here and a force of seventy-five will be employed.

Dechant Heads Case Advertising

RACINE, WIS., Oct. 2—George A. Dechant, Harrisburg, Pa., has been appointed advertising manager of the J. I. Case T. M. Co., Racine, Wis., to fill the vacancy caused by the resignation of Bertholf M. Pettit, who has joined the staff of the Curtis Publishing Co., Philadelphia.

Harding Takes Up New Detroit Job

DETROIT, MICH., Oct. 2—J. V. Harding, who was formerly the Detroit factory representative for the Goodyear Tire & Rubber Co., has left the field to become the general manager of the Neville More Room Steering Wheel Co.

New Departure to Double Output

30,000 to 35,000 Bearings a Day Will Be Made by July 1

BRISTOL, CONN., Oct. 3—The New Departure Mfg. Co., of this city played the role of host to its 2700 bearing workmen last Saturday when it staged an old-fashioned barbecue dinner of grilled lamb and all that goes with it. The dinner was one of the most pretentious ever held in New England by an automobile concern. It required eighty spring lambs which were stretched on skewers over a trench 328 ft. long filled with burning charcoal, to serve the 2700. In addition 11,000 ears of corn were needed and 30 bushels of potatoes. To make it a New England occasion all the bakeries in the vicinity were working on New England pumpkin pies. One of the outstanding features of the affair was the orderly precision in which the whole program was carried out, there not being any disorder from start to finish of the day's activities.

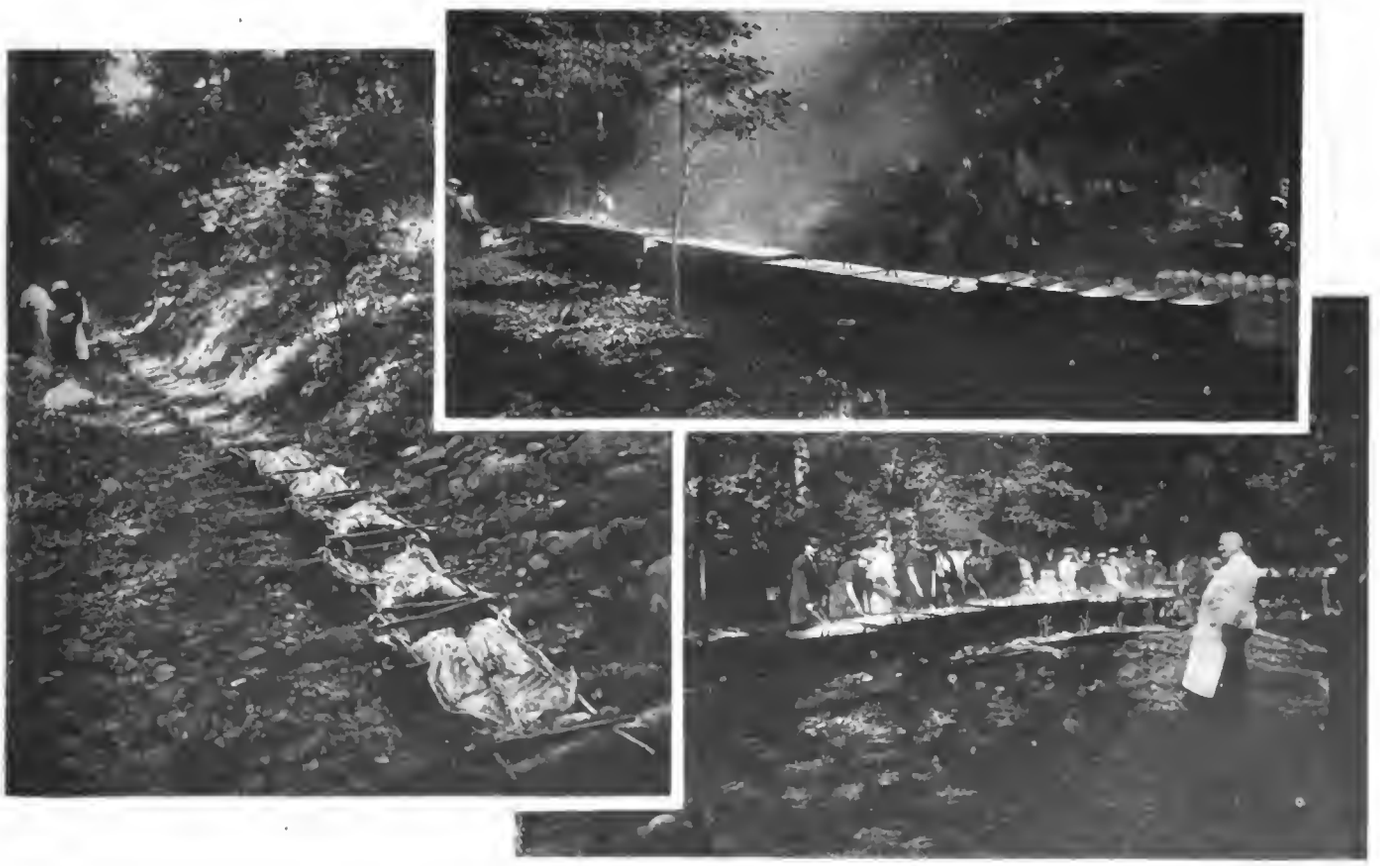
The New Departure company is making giant strides in the manufacture of its double and single row ball bearings. Its manufacturing capacity to-day is 21,000 bearings per day. This was the average production for each day of last week. The output is double what it was a year ago. It is planned to have the present output doubled by July 1 when there will be capacity for 30,000 to 35,000 bearings per day. By July 1, 4500 men will be employed.

To care for this rapid factory expansion twenty-three acres of land were purchased in this city last June. On it 102 homes for workmen's families have been completed. To care for single men the local hotel was purchased and accommodates 200.

The factory additions at present under way, are: One new four-story building, 60 by 450 ft., is one-half complete. It will be used for the manufacture of steel balls.

A contract has been let for another building 100 by 600 ft. part one-story and part three-story. It will be used for automatic work, press work, receiving and shipping. It will have two railroad sidings 950 ft. long.

At present the company is operating two factories, one in this city and the other in Hartford, Conn., where small bearings, such as required for magnetos, are manufactured. The New Departure started manufacturing double-row bearings 6 years ago, and single-row types 3 years ago. At present its output is equally divided between the two.



Scenes at the old-fashioned barbecue dinner given by the New Departure Mfg. Co., Bristol, Conn., to its 2700 bearing workmen last week. The dinner consisted of eighty spring lambs with all accessories, including stacks of New England pumpkin pies, 11,000 ears of corn and 80 bushels of potatoes

Union Products Co. Formed

$200,000 Company To Make Parts and Accessories in Rockford

ROCKFORD, ILL., Sept. 29—The Union Products Co. has been organized here with $200,000 capital and will manufacture, among other automobile parts and accessories, a piston ring patented as No. 1,195,279, by D. D. Shierk. Exclusive manufacturing licenses have been obtained by the company on six issued patents and four that are pending covering the manufacture of wire wheels.

Officers of the new company are: President and general manager, A. H. Martin, formerly vice-president and sales manager of the Burd High Compression Ring Co.; vice-president, M. R. Harned; secretary, H. F. Norris; chief engineer, W. E. Williams, consulting engineer of the American steel Foundries.

Plans for a factory have been completed and the work is being rushed on special machinery for the company.

—

Peerless Truck Order Increased to 100 Per Week

CLEVELAND, OHIO, Sept. 27—The order for motor trucks recently given to the Peerless Truck & Motor Corp., has been increased from sixty a week to 100 a week. Additions to the plant have made the increased output possible.

The new order comes through Gaston, Williams & Wigmore, Inc. If necessary the Long Island plant can be diverted from present work to fulfill the order.

—

Autocar Issues $1,250,000 in Bonds

NEW YORK CITY, Oct. 1—The Autocar Co., Ardmore, Pa., has issued $1,250,000 first mortgage 5 per cent serial bonds, dated Oct. 1 and maturing from April 1, 1917, to Oct. 1, 1921, in instalments of $125,000 each. The capital stock of the company is $2,000,000. The bonds are secured by a first closed mortgage on all the company's property, whose replacement value is in excess of $1,400,000.

For the last 2 years and 8 months, net profits of the company after depreciation have averaged $500,000 per annum, after making ample allowances for depreciation. This is equivalent to eight times the interest requirements on the new bond issue.

—

Stability Marks Material Prices

NEW YORK CITY, Oct. 3—Automobile material prices last week were featured by a steady market. There were few changes and those changes that did take place were for the most part unimportant.

The only important change was that of Pennsylvania crude oil, which rose 10 to $2.40 a barrel. Conditions in the oil field, however, are quiet despite the stir created by the oil advance. Demand for gasoline throughout the country continues strong with few changes occurring. New York gasoline continues unchanged at 22 cents a gallon.

—

Marathon Tire Increases Capital to $1,000,000

CUYAHOGA FALLS, Oct. 2—At the annual stockholders' meeting of the Marathon Tire & Rubber Co., this city, held Sept. 27, it was voted to increase the capital stock from $500,000 to $1,000,000.

—

BeSaw Capital Now $220,000

AKRON, OHIO, Sept. 30—The BeSaw Tire & Rubber Co. has increased its capital from $150,000 to $220,000.

—

Alford Becomes Nash Comptroller

DETROIT, MICH., Oct. 3—W. H. Alford has resigned as comptroller of the General Motor Corp., to take a similar position with the Nash Motor Car Co., Kenosha, Wis., effective Oct. 2.

—

Dividends Declared

Locomobile Co. of America; quarterly of 1¾ per cent on preferred, payable Oct. 2 to holders of record at close of business Sept. 30.

$2,000,000 Truck Line

Co. Formed To Operate 104 Vehicles Between N. Y. and N. J. Cities

NEW YORK CITY, Sept. 30—The New York and New Jersey Express Co. has been organized to do a general haulage business by motor trucks between this city and New Jersey points within a radius of 20 miles. The project is the outgrowth of the great increase of manufacturing in nearby cities, including Newark and Elizabeth, whose outlet for export has been limited by railroad congestion. The company plans to put into operation 104 heavy trucks, contracts having been signed for hauling 55,000 tons of goods per month.

The company has $2,000,000, 7 per cent preferred stock fully paid up and 10,000 shares of common without par value. The company's offices are at 309 Broadway.

—

Kilborn Is Liberty Sales Manager

DETROIT, MICH., Oct. 2—E. J. Kilborn, who for the past 2½ years has been the manager of the Oakland Motor Co.'s Chicago wholesale branch, has been appointed general sales manager of the Liberty Motor Car Co. He is taking immediate charge of his new duties.

A. W. Franklin has been appointed Eastern representative and Nicholas Hall and D. C. Reeves have been made Southwestern representatives of the company.

—

Weston Stays with U. S. Tire

NEW YORK CITY, Oct. 1—J. C. Weston will remain with the U. S. Tire Co., instead of going to the Mitchell Motors Co., Racine, in the capacity of vice-president in charge of sales. Mr. Weston will assume the newly created position of director of sales, thus abolishing the post of sales manager formerly held by him. O. S. Tweedy has become general branch sales manager, having direct charge of all branches.

—

Couzens Heads Detroit Police

DETROIT, MICH., Sept. 28—James Couzens, who was one of the men who started the Ford Motor Co., and who resigned as its vice-president and general manager in 1915, has been appointed police commissioner of Detroit. He fills the vacancy of the former chief who resigned suddenly.

—

Swinehart Tire Business Increases 20%

AKRON, OHIO, Sept. 28—Reports submitted by Swinehart officials showed an increase of more than 20 per cent in the

volume of business. Net sales were reported to the annual meeting yesterday, as exceeding $1,680,000, and according to T. F. Walsh, president, the business was never on a sounder basis. The factory is now turning out 500 tires a day.

The directors organized yesterday afternoon and will meet early next week to declare a quarterly dividend of 1½ per cent.

The following were elected directors: B. A. Polsky, Fred Snyder, W. M. Weldon, Charles Currie, T. E. Barry, Dr. E. L. Mather, T. F. Walsh, F. S. Long and R. E. May. Officers were re-elected.

—

New Overland Stock All Subscribed

NEW YORK CITY, Sept. 30—The $15,000,000 common stock of the Willys-Overland Co., Toledo, Ohio, which was offered to stockholders a few weeks ago for subscription of $44 a share was entirely taken up by the old shareholders, so that there will be none of the stock offered to the general public. The shares were subscribed for in proportion of one to each lot of five shares of common held, the exchange being on a share-for-share basis in respect to holders of preferred stock.

—

Hydraulic Pressed Steel Redeems Preferred

CLEVELAND, OHIO, Sept. 28—The Hydraulic Pressed Steel Co. is notifying preferred shareholders of its intention to redeem the present preferred issue at 102½ on Oct. 1.

Security Prices Rise

—

General Motors and Springfield Body Feature Market Activities

NEW YORK CITY, Oct. 3—Speculation in automobile and accessory issues last week was partly responsible for higher prices. Automobile securities have joined in the general rise of prices. At the present time interest rates are low and people are buying stocks both for speculation and investment purposes.

Last week Willys-Overland, General Motors, and Springfield Body common stock were in large demand. Willys-Overland, however, did not come up to expectations, as it was expected to rise to at least 48. Springfield Body rose 14 points to 96. The board of directors of that company has authorized the sale of 2250 shares of preferred stock to all stockholders, common and preferred, as of record, Oct. 9. These stockholders are granted the privilege of subscribing to the extent of 10 per cent of their holdings at $110 per share, plus accrued dividend from Oct. 1 to date of subscription.

General Motors made a large gain for the week, closing yesterday at 720, just 20 points higher than last week, Packard common rose 25 points to 175.

Several of the tire issues were strong though Firestone, which has featured the Akron exchange with its high price, dropped 40 points. Goodyear featured the market activities with a 25-point rise. Goodrich common rose 2 points; Portage common and preferred went up 10 points each; and U. S. Rubber common and preferred went up 2¼ and ¾ points, respectively.

The Detroit prices were fairly steady with gains ranging from a fraction to 12 points. Packard common featured the activities with a 12-point rise.

—

White Sued for $1,500,000

NEW YORK CITY, Oct. 3—Alleging that he had a contract with the White Co., made prior to the outbreak of the European War, giving him the exclusive right to sell White trucks in Russia, M. S. Friede, prominent in Russian-American trade, has filed a suit in this city for damages and commission aggregating $1,500,000 against that company, which, he states, violated the contract by permitting others to deal in its interest with Russians.

—

Hall Joins Pathfinder Co.

INDIANAPOLIS, IND., Oct. 2—D. K. Hall last week was appointed director of service of the Pathfinder Co. He had been head of the complaint department of E. C. Atkins & Co., saw manufacturers, Indianapolis, for 20 years.

—

Chemists Discuss Alcohol as Fuel

NEW YORK CITY, Sept. 29—Alcohol as a possible substitute for gasoline, and its increased industrial value were discussed by chemists attending the National Ex-

Automobile Securities Quotations on the New York and Detroit Exchanges

position of Chemical Industries in this city.

According to Dr. A. D. Little of Boston, the only fuel in sight which promises to take the place or hold down the price of gasoline is alcohol. Dr. Little declared that alcohol is the best fuel for internal combustion engines, as benzol, which had been suggested as a substitute for gasoline, is not sufficiently plentiful to keep the large number of automobiles in this country going for two days. Kerosene, he added, was out of the question.

From 1912 to 1915 the production of completely denatured and specially denatured alcohol rose from 8,000,000 gal. to 14,000,000 gal. a year.

Alcohol is being made from sawdust, according to A. H. Comey, chemist at the Du Pont Powder Co.'s laboratory, who states that it is a great commercial success and will grow accordingly.

Dr. Little stated that in the yellow pine district alone there is enough material wasted to make 600,000 gal. of alcohol a day.

Industry Gains 153% in 5 Years

1909 - 1914 Value of Products $632,831,000—Gain $383,629,000

WASHINGTON, D. C., Oct. 2—The large growth of the automobile industry in the 5-year period from 1909 to 1914, is indicated by an increase of 153.9 per cent in the value of its products, according to the Census Bureau of the Department of Commerce.

The value of those products in 1914 was $632,831,000, an increase of $383,629,000 over 1909. In 1914 there were 300 establishments engaged primarily in the manufacture of automobiles. They employed 91,997 persons, had an invested capital of $312,876,000, paid $84,901,000 in salaries and wages during the year and produced vehicles to the value of $503,230,000.

In addition, there were thirty-three establishments engaged in other lines of manufacturing which produced automobiles to the value of $6,636,920.

Adding the value of bodies and parts produced by 971 companies making this their principal business and 434 other establishments producing them as a side line, brings the total value of automobile products for that year to $649,982,990, an increase of 155 per cent over the value of production of $254,447,346 in 1909.

The greatest increase shown by the industry in the 5 years was in salaries paid, which increased 295 per cent, from $9,479,000 to $37,526,000.

The average value of production per employee increased from $2,920 to $4,336 in the respective census years.

The second largest increase was in value of materials purchased for the manufacture of cars, bodies and parts. This grew from $131,646,000 in 1909 to $356,208,000 in 1914, an increase of 170 per cent.

August Exports Total $10,068,538 in Value

(*Continued from page* 557)

valued at $772,257 and 18,884 passenger cars, valued at $16,612,060, together with parts to the value of $4,107,545, were shipped to various foreign countries. These figures look puny beside the statistics for the past 2 years.

Seven hundred and eighty-nine cars, valued at $1,963,526, were shipped to Russia in August last, while during the 8 months' period of this year the number was 2182 and the value $5,955,120. Russia did not figure in the export returns last year.

France's contribution to American automobile manufacturers in August last was the purchase of 398 cars, valued at $1,147,602, which is a big gain over the figures for the same month of 1915, when the purchases amounted to 196 cars, valued at $661,972. Likewise, during the 8 months' period the shipments to France increased from 4464 cars, valued at $11,209,798, in 1915, to 6053 cars, valued at $15,005,294, in 1916.

The big decline is to be noted in the figures for the United Kingdom. In August, 1915, there were 2290 cars shipped to the United Kingdom, the value of which was $3,530,831, while in August last the number had decreased to 294 and the value to $534,359. During the 8 months' period the exports fell from 16,784 cars, valued at $25,528,943, in 1915, to 6575 cars, valued at $10,392,259, in 1916.

There were no shipments to Germany during August of this year, or during the 8 months' period of 1916, but during the 8 months of 1915 there were four cars valued at $2,800 exported to Kaiser Wilhelm's domain.

Our trade with Canada shows a large increase during the periods under consideration, the exports having grown from 721 cars, valued at $480,677, in August, 1915, to 860 cars, valued at $750,361, in August last, and from 4682 cars, valued at $3,673,203, to 9476 cars, valued at $6,777,656, during the 8 months' periods.

In August a year ago there were 274 cars, valued at $149,319, shipped to various South American countries, while during the 8 months of that year the number was 1486 cars and the value $793,037. Herewith are the figures for South American countries, listed separately, for the same periods of this year: Argentina, 145 cars, valued at $86,470, in August, and 3798 cars, valued at $1,863,625, during the 8 months. Brazil, 29 cars, valued at $14,715, in August, and 280 cars, valued at $184,447 during the 8 months. Chile, 151 cars, valued at $85,355, and 702 cars, valued at $446,788; Venezuela, 25 cars, valued at $19,648, and 386 cars, valued at $240,982. All other South American countries, 42 cars, valued at $32,383, and 609 cars, valued at $367,759. These figures prove conclusively that South America is a field for American-built cars.

Growth of Automobile Industry from 1909 to 1914

	Census				Per Cent of Increase,		Per Cent of Increase,
	1914						
	Automobiles	Automobile Bodies and Parts	Total	1909	1909–1914	1904	1904-1909

*In addition, in 1914, 33 establishments primarily engaged in other lines of manufacture, produced automobiles to the value of $6,636,920, and 434 establishments of this character manufactured automobile bodies and parts to the value of $10,515,070; in 1909, similar establishments produced automobiles valued at $830,080 and automobile bodies and parts valued at $4,415,266.

Speedways Ban Sunday Races

Eight Championship Events of 100 Miles or Over with $100 a Mile Prizes

NEW YORK CITY, Oct. 2—Practically all of the speedways were represented at a joint meeting of the contest board at the American Automobile Association in this city to-day, when changes in the racing rules for 1917 were discussed and other necessary changes for 1917 racing recommended.

All speedways were agreed that the contest board should not sanction Sunday racing on speedways. Indianapolis, represented by J. N. Allison, was particularly strong on this ruling, due to the postponed race on the Chicago speedway being held on a Sunday, which caused the withdrawal of the Indianapolis team. David S. Reid, representing the Chicago speedway, voted for the new rule.

It was decided that eight 1917 championship events be held, one on each speedway. These championships are to be at a minimum of 100 miles, but may be at 250, 300, 350 or 500, according to the desires of the different speedways. It was voted to have a minimum cash prize at the rate of $100 per mile of race. This would make the prize for a 500-mile race $50,000; for a 250-mile race, $25,000, and for a 300-mile race, $30,000.

The eight championship events scheduled for 1917 are:

May 30	Indianapolis
June 9	Chicago
July 4	Omaha
July 14	Des Moines
July 28	Tacoma
Sept. 3	Cincinnati
Sept. 15	Providence
Sept. 29	New York

In addition to this schedule of championship events which are only to be held on speedways, 1917 dates for other speedway races were arranged for as follows:

May 19	New York Metropolitan
June 23	Cincinnati
Aug. 4	Kansas City
Oct. 6	Kansas City
Oct. 13	Chicago
Oct. 27	New York

It is expected that early next year two other speedways will be completed, namely, Philadelphia and Uniontown. Dates will have to be awarded for these as necessary.

The feeling was general that all drivers who qualify and start in 1917 races should receive some financial assistance, and it was decided to allow $100 transportation expenses to all cars qualifying and starting. Should a car finish in the money this amount would be deducted from the cash winnings of the car. If the car does not finish in the money the $100 will be awarded. In case of particularly long trips, such as Chicago to Tacoma, a total allowance of $150 per car may be made.

No 1917 championships will be held outside of the speedways as mentioned. This year the Grand Prize and Vanderbilt Cup races will be included in the championship events. It was decided to allow the first 300-cu.-in. car finishing in each of these 1916 road events to receive championship points the same as if they won the event. In other words, the first 300-cu.-in. car to finish will receive 800 points, the second 420, the third 220, etc.

Drivers will be better protected in 1917, in regard to receiving prize money, than they were this year. At Minneapolis and Sioux City drivers were required to compromise and did not get their full cash allowance. For 1917 cash prizes must be posted 2 weeks before the day of the race. This protects every driver and he will not be put to the expense of shipping his car to a speedway, because he will know before he has to ship if the money is posted or not.

New Starting Rules

While the drivers have been given every assistance under the new schedule, there are a few rules which they will have to observe. One of these is that every driver must be at the starting line 1 hr. before the start of the race. Violation will mean a cash penalty.

Pit supplies for racing cars must be in the pits at least 3 hr. before the start of the race.

Eddie Rickenbacker recommended that on speedways like New York and Chicago forty cars be permitted to start instead of thirty-two. It is expected that the contest board will revise its rules accordingly.

The drivers winning positions in the 1916 championships will receive permanent racing numbers for their cars in 1917 according to the positions in which they finished in the 1916 championships. Thus the driver finishing first in the 1916 championship will have No. 1 for his car during the entire racing season. He will also be given No. 1 driver's registration. The driver finishing second will be given No. 2 racing number for his car and also No. 2 driver's registration. This rule was strongly urged by the drivers.

To Boost Championship Fund

In order to swell the championship fund for 1917 the different speedways have agreed to pay to the contest board $10 for each car entered in a championship event. This money will all go to the 1917 championship fund.

Among those speedways represented at the meeting were: Indianapolis, J. M. Allison and L. E. Myers; New York, Harry Harkness and E. Thompson; Chicago, David E. Reid and Edward Heinze; Cincinnati, H. S. Lehman; Uniontown, C. W. Johnson; Des Moines, L. C. Dunn; Omaha, J. W. McShane.

Aitken Leads for Championship

Astor Cup Victory Lifts His Score to 2520 Points—Resta Second

NEW YORK CITY, Oct. 2—Johnny Aitken, of the Indianapolis speedway racing team, now leads the list in the 1916 racing championships. Aitken was running third previous to the Astor Cup race Saturday, but by winning this race he gained 800 points and so took first position away from Dario Resta, who was leading with 2400 points. Aitken now has 2520 points to his credit.

The order of championship standing is:

J. Aitken	2,520	Le Cain	120
Dario Resta	2,400	B. Oldfield	80
E. Rickenbacker	1,990	O. Taft	75
Ralph De Palma	1,790	E. Pullen	70
D'Alene	1,120	O. Haibe	60
Milton	690	N. Stringer	55
Mulford	620	G. Adams	55
Christiaens	540	Earl Cooper	55
Henderson	517	H. Wilcox	40
Vail	440	W. Chandler	40
D. Lewis	380	P. Watson	35
F. Galvin	340	M. Sorensen	35
J. Devigne	320	C. Johnson	30
H. Hughes	275	J. Gable	30
G. Buzane	210	Devene	30
E. O'Donnell	185	F. McCarthy	25
C. J. Devlin	140	W. J. Muller	20
A. A. Klein	125		

Uniontown's 1⅛-Mile Speedway to Open Thanksgiving Day

NEW YORK CITY, Oct. 3—The new Uniontown, Pa., 1⅛ mile board speedway, which has been erected by C. W. Johnson, a Uniontown capitalist, will be opened on Thanksgiving Day for the local meet. The speedway is a regulation board type, designed and built by Jack Prince of bicycle fame.

Speedway Heads Meet and Discuss Permanent Organization

NEW YORK CITY, Oct. 3—Steps toward a permanent organization of the different motor speedways were taken here to-day when representatives of Indianapolis, New York, Chicago and Cincinnati speedways discussed tentative plans for the scope of such an organization. To-day's meeting adjourned to meet in Chicago on Saturday, Oct. 14, when a charter for such an organization will be adopted.

The committee in charge consists of L. E. Myers, Indianapolis; David A. Reid, Chicago; E. Thompson, New York, and H. Lehman, Cincinnati. These four are taking the old Indianapolis charter for such an organization, and re-arranging it to meet present conditions. R. Kennerdell, chairman of the Contest Board, A.A.A., will meet with the committee in Chicago.

31 Grand American Entries

CHICAGO, ILL., Oct. 4—The management of the Chicago speedway has announced thirty-one entries for the Grand

American automobile race, Oct. 14. This is for 250 miles and is limited to 300-cu.-in. cars, being an A. A. A. championship event.

—

Aprahamion Sails for Orient

NEW YORK CITY, Oct. 4—A. Aprahamion sails Saturday for Africa, China and other points in the Far East, where he will represent several automobile and accessory companies, among which are: Mitchell Motors, Federal Tire, Cox Brass, New Departure, Standard Woven Fabric, Champion and Keyless Auto Lock. Mr. Aprahamion recently returned from South America.

—

Hupmobile Tour Progressing Westward

DETROIT, MICH., Oct. 2—The capital-to-capital Hupmobile left Minneapolis on its way westward, with Pierre, S. D., for its next destination. From Pierre it goes to Seattle, Wash. The car turned the 5000-mile mark between Des Moines and Minneapolis exactly on the thirtieth day of its trip, Sept. 28. On that same day the crew encountered the first rainstorm and drove in mud to the hubs.

—

New Traffic Plan for New York

NEW YORK CITY, Sept. 30—Isles of safety are now put at the intersections of Fifth Avenue with 43rd, 46th and each alternate cross street as far north as 59th to help solve the night traffic problem due to the increased vehicle travel caused by the street car strike. These isles of safety render it possible to withdraw traffic policemen from these points.

—

Eastman Heads Philadelphia Packard

PHILADELPHIA, PA., Sept. 30—Lee J. Eastman, manager of the Philadelphia branch of the Packard Motor Car Co., was elected president by the directors at a recent meeting in Detroit, succeeding Edwin B. Jackson, who is now president of the New York branch.

Harkness Trophy Race Oct. 28

—

100-Mile Event Will Carry $10,000 Prize Money—Marks Close of 1916 Season

NEW YORK CITY, Sept. 30—The 100-mile race for the Harkness trophy will be held at the Sheepshead Bay Speedway Oct. 28. It will also carry $10,000 prize money. The Harkness trophy race is looked upon as the final speedway event of the year and is expected to bring together all the drivers who have won places in the big races of the season.

The first Harkness trophy race last year was won by Dario Resta in his Peugeot in 56:55:71 or at 105.39 m.p.h.

—

Silver Takes Dort in New York

NEW YORK CITY, Sept. 30—C. T. Silver has closed a contract with the Dort Motor Car Co., Flint, Mich., by which he will represent the Dort car in the New York territory.

—

Oakland Branch Managers in 3-Day Conference at Plant

PONTIAC, MICH., Sept. 30—The 3-day annual meeting of the branch managers, distributers and salesmen of the Oakland Motor Car Co., ended to-day. It was the most enthusiastic gathering of Oakland salesmen ever held, marking the most successful year in the history of the company.

Oakland officials, branch managers and distributers took part in the many business sessions at which all matters concerning the 1917 Oakland policies as to cars, service, sales, etc., were discussed. The visitors also spent considerable time in the shops.

A banquet was tendered to the visiting Oakland men by the officials of the Oakland Motor Car Co., at the Hotel Statler, Detroit, Sept. 29. Among those who informally addressed the distributers and salesmen were Fred W. Warner, now president of the company; C. B. Voorhis, now vice-president; J. T. Shaw, treasurer of the General Motors Co.; W. L. Day of the General Motors Truck Co.; H. H. Rice, personal representative of W. C. Durant; Carl M. Green and W. C. Durant, who came unexpectedly.

—

Takes Over N. Y. Saxon Factory Branch

NEW YORK CITY, Oct. 1—Distribution of the Saxon in this city and surrounding territory, formerly in the hands of a factory branch, has been taken over by the Saxon Motor Car Corp., recently organized. G. S. Morrow is president.

—

Newman Resumes Former Position

DETROIT, MICH., Oct. 4—Harry Newman, who recently resigned the presidency of Harry Newman, Inc., Chicago and Milwaukee Chalmers distributers, has again taken his old position.

—

Lancia Adopts H. & N. Carbureter

NEW YORK CITY, Sept. 30—The Lancia Co. has adopted the H. & N. carbureter as standard equipment, the type used being of special design for this car.

—

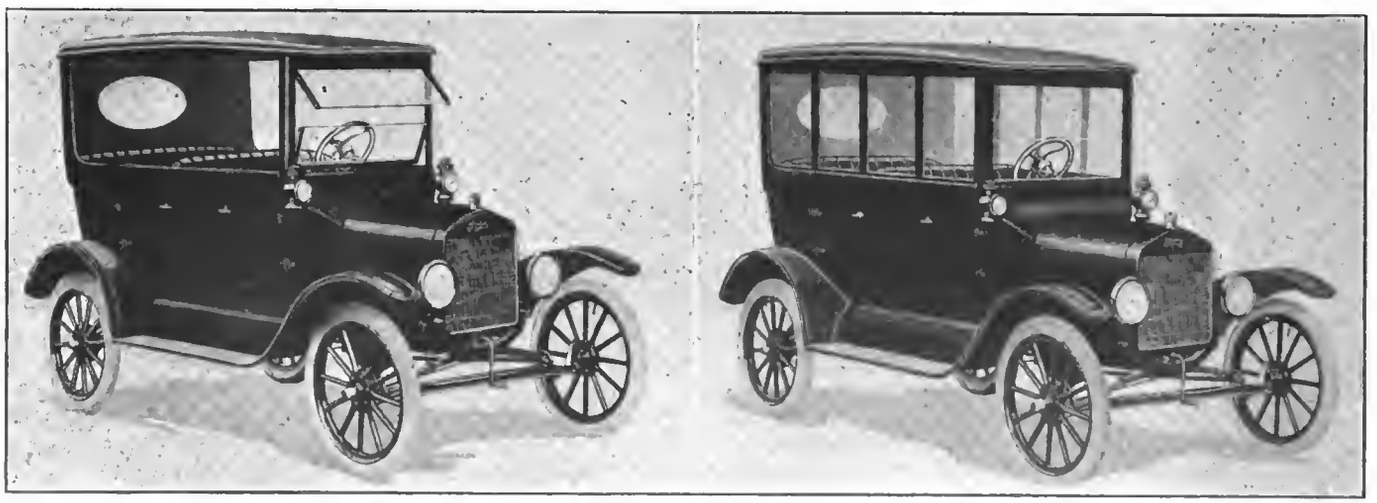
Lexington-Howard Rayfield Equipped

CONNERSVILLE, IND., Oct. 3—The Lexington-Howard Co., this city, has added the Rayfield carbureter as standard equipment.

—

Senator Morgan to Sell Saxons

NEW YORK CITY, Oct. 4—W. J. Morgan, familiarly known as "Senator," and pioneer in automobile beach races in Florida, has organized the Morgan-Farr Motor Co., Inc., Newark, N. J., to sell Saxon cars.



The Motor Products Co., Indianapolis, Ind., has commenced manufacture of the convertible sedan top for Ford cars illustrated above. It is easily attached in the first instance, and the windows can afterward be removed quickly in fair weather or replaced for bad conditions. It is supplied for $125. This is the first of a series that will be put on the market; tops of similar design for Chevrolets, Overlands, Maxwells, etc., will be added shortly

Factory Miscellany

Brown Heat Department Completed—The Brown Co., Syracuse, N. Y. has been completed. Four oil-burning furnaces have been installed with a capacity of sixteen large pots per furnace, or 1200 to 1600 bolts per heat, each furnace. Three heats every 24 hr. can be successfully run, or 3600 to 4800 pieces for each furnace in a complete day.

Bulldog Plant for Plymouth—Adelbert Work, of Chicago, head of a company manufacturing Bulldog shock absorbers and other accessories, has announced plans for removing the plant from Chicago to Plymouth, Ind., as soon as a factory building can be erected. Ground for the plant has been purchased. The plant will be 38 by 38 feet.

Patent Ring Plant—The Ford-Davis Mfg. Co., St. Louis, has selected 2642 Locust Street as the location for the new factory and will manufacture the Ga-Saver piston rings, of which Jack Ford and T. D. Davis, the active members of the firm, are inventors.

American Tire Fabric Company Builds—The American Tire Fabric Company, New Bedford, Mass., will start work soon on a 76 by 194-ft. two-story factory.

1250 Men Erecting Goodyear Buildings—The Goodyear Tire & Rubber Co., Akron, Ohio, is employing 1250 men in the erection of its new buildings. Goodyear building operations now include more room for the office force as well as the factory workers. Within a year the company expects to be employing 20,000 men, making Goodyear products.

Boone Tire to Build in Belvidere—The Boone Tire & Rubber Co. has secured an option on ten lots in Belvidere, Ill., on which it will erect a plant in two units, the first of which will be housed in a building 60 by 120 ft., in which machinery will be installed for manufacturing fifty tires a day. Immediately upon the completion of this unit two additional buildings will be erected. The complete plant will have a capacity of from 150 to 200 tires per 10-hr. day.

1000 Sets of Hayes Wheels in Day—The Hayes Wheel Company recently built 1000 sets of Ford wheels in one day at its Anderson, Ind., plant. The 4000 wheels were produced by the regular force of 300 men running day turn. A night shift of 300 employes is to be added so that the required capacity of 2000 sets of Ford wheels daily may be reached.

Cadillac Truck Plant Completed—The foundation work and the first floor of the new plant of the Cadillac Auto Truck Company, Cadillac, Mich., is completed. The structure is two stories high, 100 by 180 ft. It will be occupied Nov. 15.

Mitchell Rushed—The demand of the Mitchell Motors Company on the Mitchell Wagon Company, both of Racine, Wis., for automobile bodies, has necessitated the wagon company increasing its working force as well as the provision of additional room for the automobile body department.

Budd Company Adds—The Edward G. Budd Manufacturing Company, Philadelphia, Pa., maker of steel automobile bodies, etc., has awarded a contract for the electrical equipment for its recent plant additions at an estimated cost of $20,000.

Spokane Lumber Company Makes Bodies—The Robbins Lumber Company, Spokane, Wash., is planning a four-story addition to its plant at 1218 Railroad Avenue, where it manufactures bodies for automobiles. The addition will be 16 by 30 ft., of concrete and brick.

Advance Felt Moves—The Advance Felt Specialty & Cutting Co., Chicago, has moved into its new quarters at 318-322 South Jefferson Street. This is the second move for the company within the last eighteen months, due entirely to the rapid growth of the business. The new building is of the "daylight" type, two stories with full concrete basement, brick construction with sprinkler system, equipped throughout with specially designed machinery for the cutting, striping and punching of felt cloth, rubber, and analogous materials. The Advance people specialize in the manufacture of felt parts for automobiles, motors, transmissions, axles, etc.

TRACTOR

Oct 14-29—Dallas, Tex., Demonstration, Texas State Fair.

The Week in the Industry

Twin City News — The Chevrolet Motor Co. and the Bearings Service Co., Minneapolis, will occupy a new building on Harmon Place near Hennepin Avenue.

The St. Paul Chandler Co. has been formed to sell Chandlers and R. W. Pantel will be sales manager.

The Overland Co. has shipped from the factory branch in St. Paul forty-two carloads of stock cars to Vladivostock, Russia, for use of the government. The shipment, 126 machines, valued at $150,000, left recently for Seattle.

Washington Items — George Farnsworth, Seattle, Wash., has opened salesrooms at Broadway and Pine Street, where he will distribute Abbott-Detroit machines for the territory of Washington, Oregon and northern Idaho.

The Stegeman motor truck has entered the Northwest field, the F. H. Barshar Motor Co. having secured the distribution, with headquarters in Seattle.

M. C. Davies has secured the exclusive agency in Tacoma and Pierce County for the Velie line.

R. A. Mueller and L. W. Harkins have withdrawn from the Universal Motor Co. in Tacoma, and have formed the Mueller-Harkins Motor Co. to distribute Buick cars and G. M. C. trucks in Pierce County.

The Chevrolet Northwest Co. has opened a branch in Tacoma with a complete line of parts and accessories, with A. J. Smith as director of sales.

Ohio News Items—The Central Auto Vehicle Co., Columbus, has taken the central Ohio agency for the Grant, formerly held by the Miller-Main Garage.

Harry Ensign has purchased the interest of his brother, Bert Ensign, in the Ensign Motor Co., Springfield, agent for the Cadillac and Cole.

The Dobyns Motor Car Co., Hilliard, has taken the agency for the Chalmers, covering all of the counties of Union, Madison and Delaware. Branch salesrooms will be opened in London, Marysville, Delaware and Plain City.

Geddes with Scripps-Booth — B. F. Geddes has been appointed sales representative in the Middle West for Scripps-Booth Co. He was formerly with the Grant and Maxwell companies.

Niekirk with Galion Truck Co.—J. D. Niekirk, foreman at the plant of the Sommer Motor Co., Bucyrus, Ohio, has resigned to become shop superintendent of the Galion Dynamic Motor Truck Co.

Willis Joins Singleton-Hunting Co.—P. P. Willis has joined the Singleton-Hunting Co., Cleveland, Ohio, advertising agent, as vice-president and manager of production. James P. Hunting becomes treasurer and continues in charge of merchandising. These changes were rendered necessary by the increasing automobile accessory business of the company.

Rennard Joins Ross — Ben Rennard has been appointed special sales representative for the Ross Automobile Co., Detroit. He has been with the Locomobile, Chalmers and Chandler organizations.

Zadek Goes to Temple Co.—James L. Zadek, superintendent of the police department shops, Chicago, Ill., has resigned to take charge of the testing and assembling departments of the Temple Mfg. Co., 54th and 22d Streets. The Temple company makes gasoline engines and machine tools.

Diver to Design Cole Bodies.—B. M. Diver, body designer and engineer, has become connected with the Cole Motor Car Co., Indianapolis, Ind. Mr. Diver's special work is in connection with the present Cole-Springfield bodies and he will devote his attention to other bodies now contemplated.

Gilbreath Detroit Club Mgr.—William Sydnor Gilbreath has resigned as traveling secretary of the Dixie Highway Association to become manager of the new Detroit Automobile Club. Mr. Gilbreath has been one of the best-known figures in the development of through routes in America, having been associated with Carl Fisher in the early days of the Lincoln Highway, and after the preliminary work on that was done carrying forward similar work for the Dixie Highway Association.

Williams with Chanslor & Lyon.—Harrie R. Williams has resigned as accessory sales manager of the Gibson Co., Indiana Overland distributer, to become vice-president and general manager of the Chanslor & Lyon Co., San Francisco, accessory dealer and distributer. He will be succeeded by E. C. Kurman, manager of the Gibson Co.'s branch at Logansport, Ind.

$600,000 Chevrolet Co. in Texas.—The Chevrolet Motor Co. of Fort Worth, Tex., was chartered this week with a capital stock of $600,000. Incorporators are W. C. Stripling, Sam Davidson and B. C. Bradford of Fort Worth and W. C. Durant of New York.

Johnson, Tractor Expert, Sails for Russia.—Nelson Johnson, tractor expert for the Emerson-Brantingham Co., Rockford, Ill., sailed this week for Vladivostock, Russia, to line up business for delivery after the war. Johnson has spent several years in Spain, Argentina and Mexico, selling tractors, and will remain in Russia for a year or more, being similarly engaged.

Gibson and Hammerton Resign.—Lester H. Gibson, formerly general manager of the Gibson-Hollister Mfg. Co., Boston, Mass., and Alfred J. Hammerton, formerly superintendent, have resigned to become connected with the Higginson-Gibson Mfg. Company, Inc. This concern makes automobile electric lamp connectors and other accessories.

Chandler's N. Y. Office Moved—W. S. M. Mead, vice-president of the Chandler Motor Car Co., Cleveland, Ohio, and in charge of exports, has moved his offices from the Brady-Murray Motors Co., Chandler distributer in New York City, to 1790 Broadway.

Picard Moves—A. J. Picard & Co., New York City, accessory dealer, has outgrown the present quarters at 1720 Broadway, and will build a five-story building at Sixty-first Street to be finished around Jan. 1.

Ryall Joins Poertner—J. B. Ryall, prominent in automobile racing a few years ago, has been appointed manager of the Poertner Motor Car Co.'s truck department, New York City.

Gewinner Resigns—J. K. Gewinner has resigned as president and general manager of the Johnson-Gewinner Company, Atlanta, Ga., accessory dealer.

Bulask Joins Frisco Company—H. C. Bulask has joined the Hartmann Motor Sales Agency, San Francisco, in the capacity of wholesale manager for the Elgin Six. This company also handles the Lozier and Paige.

Philadelphia Items — The Pratt & Moser Motor Co., Fifty-seventh and Chestnut Streets, has opened a showroom and service station at 833 North Broad Street, and will handle the Pilot and Elcar automobiles.

The L. S. Bowers Co., 245-47 North Broad Street, agent for the Cole and Grant cars, has opened a used-car department across the street, at 256.

The W. Clark Grieb Co., Briscoe agent in this territory, has moved to its new salesroom and service station, 851 North Broad Street.

Gaulke Joins Heil—W. H. Gaulke has resigned from the A. B. and B. Specialty Company to join the Heil Company, Milwaukee, Wis., in charge of the automobile gasoline tanks and specialties.

Stewart V-Ray Spark Plug

An Instant Success and A Continuing One

Inquiries and orders are pouring in—and in answer the new Stewart V-Ray Spark Plugs are being shipped out in larger quantities every day.

The demand is steadily growing.

Car owners who formerly clamored in vain for V-Rays will now be able to get them.

And dealers who formerly had to offer customers inferior plugs because of the limited V-Ray production are once more displaying V-Rays on their counters.

The demand for this famous quality plug is already large and growing.

And V-Ray production will keep up with it.

Wise dealers are getting in on the ground floor. Wire today.

"It will pay you to see that the car you own is equipped with Stewart Products"

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, OCTOBER 12, 1916—CHICAGO NO. 15

Form Eastern Motors Syndicate

Organization To Plan High-Grade Car To Be Built by Eastern Motors, Inc.

HARTFORD, CONN., Oct. 10—The Eastern Motors Syndicate has been organized and financed in this city for the purpose of designing and preparing all details of a proposed high grade automobile. This new car will incorporate many refinements that will appeal to the most fastidious. The manufacture of the car will be taken over by the Eastern Motors, Inc., which will be organized for purposes of manufacture and sale, the development, however, resting with the Eastern Motors Syndicate.

The Eastern Motors Syndicate has at present an option on two plans and a final selection of a factory location is expected to be made in the near future. Allen Shelden, chairman of the Eastern Motors Syndicate, has the organization work in charge, and has developed plans of co-operation with dealers in connection with merchandising of product.

Others connected with the organization are: Willis D. Upson, Waterbury, Conn., as treasurer. He is a man familiar with the automobile industry. L. S. Hubbard, Bridgeport, Conn., is secretary; and is manager of a large business in that city. F. A. Law, formerly chief engineer of the Pope Mfg. Co., and more recently connected with Selden, Brewster and Gaston, Williams & Wigmore, is chief engineer.

—

Webster Heads Racine Rubber

RACINE, WIS., Oct. 9—Stuart Webster has been elected president of the Racine Rubber Co., Racine, Wis., manufacturer of tires and tubes, to fill the vacancy caused by the resignation of H. L. McClaren, who recently resigned as president of this company and also of the Mitchell Motor Corp., Racine, the ownership of which is closely allied with the tire company. Mr. Webster was one of the original officers of the tire company, which was first established in March, 1910.

He first held the position of treasurer, but in 1915 he was elected vice-president and general manager. This position has been turned over to Louis T. Vance, who has been factory manager since 1911. H. C. Severance remains as secretary and general sales manager. The office of treasurer is combined with that of president.

The Racine Rubber Co. is now doing a business amounting to $5,000,000 annually and employs from 900 to 1000 men. The daily output exceeds 1500 tires and the same number of tubes.

—

Hudson 1917 Price $175 Higher

NEW YORK CITY, Oct. 10—On Dec. 1, the Hudson Motor Car Co. will advance the price of its various models by $175. On May 9 last, the company raised its prices $100 on its various models, due to the very greatly increased cost of materials.

The new price on the phaeton model and the two-passenger will be $1,650, while the four-passenger roadster type will sell for $1,700; the cabriolet at $1,950 and the sedan at $2,175.

—

Chalmers to Raise Prices $70

DETROIT, MICH., Oct. 9—The Chalmers Motor Co. announces an increase in the price of several of its models. The seven-passenger touring car now selling for $1,280 will be increased to $1,350; the sedan selling at present for $1,760 will cost $1,850; the town car and limousine will raise in price from $2,480 to $2,550. The increase in price becomes effective on Dec. 1.

Perfection-Stanweld Merger?

Negotiations Now Under Way May Mean Consolidation of Cleveland Firms

CLEVELAND, OHIO, Oct. 7—A merger of the Perfection Spring Co. and the Standard Welding Co., both of this city, may shortly be completed. The consolidation has been approved by the boards of directors of both companies and now awaits the ratification of the stockholders.

The combination would result in one of the strongest factors in the industry, producing among other parts and accessories, automobile springs, heaters and rims.

The capital stock of the Perfection Spring Co. is $2,500,000 authorized, which is divided into $1,000,000 preferred and $1,500,000 common; $1,250,000 of common stock has been issued.

The capital stock of the Standard Welding Co. is $2,225,000 of which $2,206,800 is outstanding all of which is one class.

Holders in both companies will be given the privilege of converting their securities into those of the new corporation. This company will have an authorized stock of $25,000,000 common stock and $10,000,000 7 per cent cumulative stock preferred. Borton & Borton, a Cleveland investment house, will underwrite the stock to be issued. The two companies have combined total assets of $10,000,000.

The Perfection Spring Co. which manufactures automobile springs and at present supplies more than thirty large automobile makers of this country, employs between 1700 and 1800 men. It commenced business 10 years ago in

4000 Wintons for Next Year

$1,500,000 New Capital Will Be Used to Enlarge Production Facilities

CLEVELAND, OHIO, Oct. 7—Following the sale of $1,500,000 7 per cent cumulative preferred stock to Borton & Borton, as reported in THE AUTOMOBILE last week, the Winton Co. will enlarge its production facilities with the new capital thus provided. For the past 12 months orders have been filled from 6 weeks to 6 months later than specified and, while the company intends no change in its policy of limited production, more flexibility was necessary.

Up to 1916 the Winton Co. built between 1200 and 1300 cars a year, but during the past 12 months over 2000 cars have been sold and production for the coming year is estimated at 4000. The company's production of gas and oil engines of the Diesel type has also increased and a part of the new capital will be devoted to the engine factory.

—

McCornack Is Hudson Sales Manager

DETROIT, MICH., Oct. 5—O. H. McCornack, who for the past 6½ years has been the purchasing agent for the Hudson Motor Car Co., has been appointed to succeed E. C. Morse, who recently resigned to become the vice-president in charge of the sales division of the Chalmers Motor Co. The Hudson company also appointed O. Barit, former assistant purchasing agent, to succeed Mr. McCornack as purchasing agent.

—

Bailey To Manage Cook's Patent Assn.

DETROIT, MICH., Oct. 5—G. Franklin Bailey has been appointed manager of the Cook's Patent Association, which controls the claimed basic patent for truck-making attachments for pleasure cars. Mr. Bailey was formerly the advertising manager of the New York *Globe* and more recently was connected with Charles T. Silver, Chalmers distributor in New York.

—

Pulcher Heads New Detroit Club

DETROIT, MICH., Oct. 9—M. L. Pulcher will be the first president of the new Detroit Automobile Club when the organization perfects its charter membership plans. Mr. Pulcher is the vice-president and general manager of the Federal Motor Truck Co.

W. S. Gilbreath, secretary of the club, announces that charter members are rapidly being signed and that the 1000 mark will soon be reached.

The club incorporates a novel and interesting clause in its charter membership application which reads: "We do further agree, in furtherance of the interests of said Organization, to abide by and comply with all State Laws and City Ordinances governing and controlling traffic on the public highways in the State, and streets and highways in the cities, and to co-operate with and assist officials in every manner possible in compelling proper enforcement of said laws."

—

Gray Heads Hess-Bright Co.

PHILADELPHIA, PA., Oct. 7.—B. D. Gray has been elected president of the Hess-Bright Mfg. Co., this city, manufacturer of ball bearings. Mr. Gray, who was formerly vice-president, succeeds F. E. Bright, who will remain identified with the company as chairman of the board.

—

Hamilton Chief Engineer for Oakland

DETROIT, MICH., Oct. 9—A. C. Hamilton of the experimental department at the King Motor Co. plant in Detroit, has been appointed to be chief engineer for the Oakland Motor Co., to succeed Eric Wahlberg who recently resigned to join the Nash organization in the Jeffery plant at Kenosha, Wis.

—

Weaver Returns to Timken Axle

DETROIT, MICH., R. B. Weaver has returned to the Timken-Detroit Axle Co., as chief engineer, succeeding J. G. Perrin, who resigned.

—

Anderson Is Madison Sales Mgr.

INDIANAPOLIS, IND., Oct. 7—Harry W. Anderson has been appointed sales manager of the newly organized Madison Motors Corp. of Anderson, Ind. Mr. Anderson was formerly sales manager of the Stutz Motor Car Co.

—

Newmark Succeeds Eustis with Chevrolet

NEW YORK CITY, Oct. 9—John R. Eustis has resigned as advertising manager of the Chevrolet Motor Co. and will be succeeded by J. H. Newmark., advertising manager of the Apperson Bros. Automobile Co., Kokomo, Ind. Mr. Eustis, before joining the Chevrolet company last May, had been motor truck editor of the *Evening Mail* for 5 years. Mr. Eustis will devote most of his time to publicity work.

—

Bias Is Mitchell Purchasing Agent

RACINE, WIS., Oct. 7—M. C. Bias has been appointed purchasing agent of the Mitchell Motors Co., this city, succeeding Guy Morgan, resigned. Mr. Bias has been identified with the Mitchell company since 1909.

Standards Men to Meet Oct. 18

Will Hold Its Session in Bureau of Standards at Washington

NEW YORK CITY, Oct. 10—By the courtesy of Dr. Stratton the October meeting of the S. A. E. standards committee will he beld in the U. S. Bureau of Standards at Washington, next Wednesday. On Monday and Tuesday there will be various division meetings and these may also be held in the bureau.

At Wednesday's meeting practically all the divisions will have reports to make and some of them are of particular interest. Firstly the electrical equipment division has much to say on the subject of headlamps and the standardization which is going to settle the glare problem. This work is nearing completion. In the evening, after the meeting, some demonstrations will be made with actual lamps to show the committee how the division has approached the problem, and to indicate the effect of the application of the standards suggested.

Will Discuss Trucks

The military truck specifications are not in shape to go before the committee in the form of a report, but they will be discussed informally and no doubt the division will receive many valuable suggestions. The proposed details of standard truck control will be ready for acceptance and this is one of the most important parts of any truck standard that can be created. Of course it is not intended that this standard control shall apply only to military vehicles, but to all trucks as far as possible. A standard control would mean that any driver could operate any truck with equal safety. Having once learned on one machine he would find nothing strange in handling another.

The October meeting is not faced by so full a program as was the meeting in May, since less committee work is done in the summer months which make the vacation season. None the less, nearly every division has something to report and a number of new standards will be ready for transmission to the society.

—

Wright Is Cassidy Special Representative

NEW YORK CITY, Oct. 7—E. C. Wright, former eastern district sales manager for the Carter Carburetor Co., has joined the selling staff of the E. A. Cassidy Co., this city, as official representative. Mr. Wright will spend considerable time in the automobile manufacturing centers, in addition to looking after the selling interests of the company among the large distributers.

Used Car Show for Chicago

City's Automobile Trade Assn. Schedules Exhibition in Coliseum for May 8-14

CHICAGO, ILL., Oct. 10—A used-car show will be held May 8 to 14 in this city at the Coliseum by the Chicago Automobile Trade Assn., which has been working on this proposition for a year.

Space in the Coliseum will be sold at 40 cents per sq. ft., assignment to be by public drawing. The dealers will show rebuilt cars which they represent and other used cars they have taken.

The trade association will get one-half the profits, which will be divided among the members, the Coliseum getting the other half.

Tickets are to be 25 cents each. It is figured it will cost the exhibitors $60 per car for space.

—

Boone Is Disco Chief Engineer

DETROIT, MICH., Oct. 9—S. W. Elston, president of the Disco Electric Starter Corp., has secured John T. Boone as chief engineer for the Disco company. Mr. Boone was formerly chief engineer for the Heinze Electric Co., of Springfield, Ohio.

—

Rainier Motor Corp. Chartered

NEW YORK CITY, Oct. 10—The Rainier Motor Corp. has been chartered in this state with a capital to $600,000 to manufacture the Rainier truck. The incorporators are J. T. Rainier, P. N. Lineberger, and J. A. Rainier.

—

Trailer Makers Form Association

DETROIT, MICH., Oct. 10—Fifteen trailer manufacturers met here today and formed a permanent organization to be styled the Trailer Manufacturers Association of America. It contemplates a model trailer ordinance and other legislation and publicity. The officers are: President, C. A. Geiger, president Troy Wagon Works, Troy, N. Y.; vice-president, Miss K. Gleason, Rochester Trailer Co., East Rochester, N. Y.; secretary-treasurer, J. C. Endebrook, Sechler Co., Cincinnati. The temporary chairman was C. W. Shipley, of the Sechler Co. A. W. Keesler, Watson Wagon Co., Canastota, N. Y., acted as temporary president. An executive committee of four was named.

—

May Copy Ford's Sales Plan

DETROIT, MICH., Oct. 7—The new departure of the Ford Motor Co., whereby it has given up its branches and allowed a general scramble for agencies, has set some of the big officials of other concerns thinking, with the result that before show season there is likely to be a similar plan adopted by others. Some of the companies that are making large productions now calculate that where they have one large distributor for a place, say like New England, a group of Southern, Western or Pacific States are wondering if it would not be possible to put over more cars if there were not one big distributor directing the affairs of his subagents, and have a lot of dealers, in fact like Ford, more than one in big cities.

—

Metz Sales Plan Similar to Ford's

WALTHAM, MASS., Oct. 7.—The Metz Co. has signed a lease to take over a new building that is in process of erection on Commonwealth Avenue, Boston, Mass., which will be its general sales and service station for that city. It has sold its lease on the building 195 Massachusetts Avenue, Cambridge, Mass., where it conducted its sales department since it closed its Boston office. The general sales will be conducted from the factory at Waltham until the new building is ready for occupancy.

The Metz company inaugurated a plan similar to the Ford of closing its branches and substituting agencies, and at Worcester the Reo-Worcester Co. is its agent, while the Fiske & Naylor Co., at Providence, R. I., is its agent there. When the Boston building is finished the Metz company will also have other agents in that city handling its line.

—

Stanley Is Briscoe Asst. Sales Manager

DETROIT, MICH., Oct. 6.—John L. Stanley has been appointed assistant sales manager of the Briscoe Motor Corp., Jackson, Mich. Mr. Stanley was formerly with the Paige distributer at Kansas City and prior to that time with the Mitchell and Jeffery Co. as district sales manager.

—

War Exports Gain $86,802,054 Over 1914

NEW YORK CITY, Oct. 10—Shipments of U. S. A.-Built automobiles and motor trucks to Europe for war purposes during the fiscal year 1916 totaled $86,802,054 more in value than in the fiscal year 1914, according to statistics issued by the U. S. Treasury department. The total value of cars and trucks shipped to warring countries for military purposes this year was $120,000,860, as compared with $33,198,806 in 1914.

—

Wisconsin Trucks in Production

SHEBOYGAN, WIS., Oct. 7—The Myers Machine Co. is now making regular deliveries of the Wisconsin motor truck. The company was reorganized several months ago to purchase the Wisconsin Motor Truck Co., Baraboo, Wis.

McFarlan to Make Expansion

Reincorporates with $3,000,000 Capital as McFarlan Motor Corp.

CONNERSVILLE, IND., Oct. 10—The McFarlan Motor Co. has been reincorporated at $3,000,000 as the McFarlan Motor Corp. and will expand its business. The officers, car and price will remain the same but later the company will build a high-priced truck. The incorporation is under Delaware laws. The old capitalization is comparatively very small, and the new plan means considerable added capital.

—

Chandler to Continue Present Model

CLEVELAND, OHIO, Oct. 9—The Chandler Motor Car Co., this city, will continue its present model for the coming season and there will be no reduction in the price. There is a probability that the price will be advanced.

—

New Era Buys Sly Tire Specialties

NEW YORK CITY, Oct. 10—The tire holder and tire lock business of the W. W. Sly Mfg. Co., Cleveland, has been purchased by Smalley Daniels, president of the New Era Spring & Specialty Co., Detroit, which has for 5 years been the sales department for those products.

The New Era company will remove the business to Detroit or Grand Rapids and combine its shock absorber and bumper plant and increase the tire holder production.

—

Hoyt Joins Bour-Davis

DETROIT, MICH., Oct. 10—G. W. Hoyt has been made production and factory manager of the Bour-Davis Motor Car Co., this city. He was formerly publication engineer of the company. Before joining this company, Mr. Hoyt was associated with Ray Harroun as assistant in the engineering department of the Nordyke & Marmon Co., Indianapolis, and later with the Maxwell company.

—

General Tire Adds Two Directors

AKRON, OHIO, Oct. 7.—G. F. Burkhardt of Akron, and J. A. Diebolt of Cleveland have been elected directors of the General Tire & Rubber Co., increasing the board to seven members. Charles Herberich, vice-president and treasurer of the Depositors Savings & Trust Co., has been elected treasurer. Other officers of the company are: M. O'Neil, president; W. F. O'Neil, vice-president and general manager; and W. E. Fouse, secretary.

BRAZIL

Large Field for Motor Truck Sales in State and City of Sao Paulo—Rio de Janeiro Can Also Use a Great Many Commercial Vehicles

Part III

By David Beecroft

EDITOR'S NOTE:—This is the third of a series of articles embodying the close observations of automobile and general trade conditions in Brazil made by Mr. Beecroft, Directing Editor of THE AUTOMOBILE, during a 10-weeks' trip through Argentina, Uruguay and Southern Brazil as a delegate of the United States Government and member of the Argentine Return Visit Committee. Subsequent articles will further analyze the possibilities of selling cars, trucks, and tractors in the United States of Brazil.

BOTH the State and City of Sao Paulo present a large field for motor truck sales, although one handicap in the State's road system is that most of the roads are private ways through the large plantations. There is not a completé system of public highways as we have in the U. S. A. Because of this when you make a trip in an automobile across the country you are constantly bothered opening and closing gates which admit you to different plantations. You frequently find one such gate every 3 or 4 miles. These gates are often padlocked and you must get permission to proceed from the owner before it swings open to admit you.

The city of Sao Paulo is a good market for trucks. True, the city is not nearly as large as Buenos Aires or Rio de Janeiro but it is growing very rapidly. To-day its population is approximately 500,000 and in 10 years it is expected there will be over 1,000,000 people. The buying capacity of Sao Paulo city for automobiles and motor trucks can scarcely be gaged by a population estimate. Its purchasing capacity is much greater than either Rio, Buenos Aires or Montevideo in ratio to population.

The city has increased nearly twenty-fold in the last 30 years. The great activity in the coffee area has been largely responsible for this growth, but to-day the city has within its boundaries so many activities and distributes to so large an area that its future as the second greatest and perhaps the greatest distributing city in all South America seems assured. Buenos Aires will unquestionably lead for many years, but Sao Paulo is sooner or later going to pass Rio as a great city. Perhaps this may not be in population but in energy, influence and progressiveness.

Ideal Streets for Trucks

The city is well paved and almost ideal for motor trucks. The newer streets are very wide. It is true that several of the older streets in the center of the city are narrow, but they are generally one-way thoroughfares, which helps traffic materially. As with all South American cities, the pavement is stone block with asphalt on the finer avenues. Sao Paulo reminds you much of Buenos Aires, with its wide streets radiating into every part of the city. These streets have double trolley lines, fine wide sidewalks and the usual strip of greensward between the curb and the sidewalk.

With relation to the truck-buying capacity of Sao Paulo it is best to bear in mind that there is an unusual concentration of business activities. An example: One hardware importer has large blocks of stock in six other diversified interests, such as a wire factory, a textile mill, a match factory, a hardware metal stamping plant and a wholesale provision store. Reaching this one man opens the possibility of selling trucks in six different industries. This is true with regard to many of the leading business men of the city. A second example: One large industry owner has a controlling interest in ten different concerns, some merchandising and others manufacturing plants. In addition he has a large interest in twelve other organizations. Here is a man with great influence in twenty-two different organizations. This particular person has his own steamboats and does an enormous business. Selling trucks to such a person and through him making it possible to reach twenty-two concerns, gives a new phase to motor truck sales and should tend to make the introduction of trucks into the city relatively easier and simpler than if individuals were largely tied to a single organization.

National City Bank Branch

In Sao Paulo the National City Bank of New York has had a branch for 2 or 3 years. This branch is already doing good work to make it easier for U. S. A. motor truck makers to do business in the City of Sao Paulo and also throughout the entire State. The bank maintains a large commercial department whose duties are entirely concerned with securing information on the different industries of the State as well as on the financial standing and the business honesty of the many firms of the State. This department has a corps of competent workmen, the same as in all of the other cities in South America where this bank has recently opened branches.

From this bank it is possible to get the financial standing of any house with which a U. S. A. truck maker would hope to open agency relations. It is possible to-day to get as accurate information on such firms as on firms in New Orleans or Buffalo. All of such arrangements should be taken up through the main office of the bank in New York City.

We spent nearly half a day with the head of this department going over the various industries in the City of Sao Paulo with the hope of seeing how many concerns are large enough and financially strong enough to be owners of motor trucks or motor delivery wagons. The bank has a complete

list of all business organizations in the city and has investigated them individnally. Many of these concerns are manufacturers, others are large importers, others large wholesalers and others engaged in the various lines of business that are to be found in any city.

162 Firms Need Trucks

We found there are 162 large concerns in the city who should be owners of motor trucks. Many of these should own fleets of trucks and delivery wagons. This estimate of 162 concerns is very conservative. No effort was made to make a big list, rather the idea was to be ultra conservative. It would be possible to double this number if you wanted to include those whose business is large enough to warrant the use of trucks. We differentiated between concerns having a business large enough to warrant their using motor trucks and those who are large enough and who are also financially strong enough to warrant their buying such at once.

This list of 162 large and financially strong concerns included all lines of business and the following gives a few of the more important ones. However, it must be remembered that these are only the more important of the industries of the city, or those who are obviously most in need of the improved transportation facilities brought by the introduction of motor trucks into their businesses. There are a number of other fields which should be considered.

Agricultural Implements.—There are twelve large firms importing such machinery from the U. S. A. and Europe. They generally carry very varied lines, including large supplies of spare parts. Not infrequently these firms sell automobiles, and also deal in mill machinery and machinery that can be nsed in garages such as lathes, drills, presses, etc.

Biscuit Factories.—There are two large ones and many smaller ones. The large ones should be using motor trucks. There are several of the smaller ones that would be warranted in using light delivery jobs.

Breweries.—There are two large breweries in the city and one in Ribeirao Preto, a city of 25,000 and 241 miles north in the heart of the coffee country. The use of trucks in the brewery trade in Sao Paulo is identical with that in any U. S. A. city.

Wholesale Clothing.—Ten large concerns are engaged in this work. They have to transport the goods from the depot to their warehouses and then make city distribntion to the different retailers. There is much teaming from the warehouse to the depots for shipment to interior cities and towns.

Dry Goods Importers.—There are in addition to the above nine dry goods importing houses. These firms have the usual use for trucks, transporting goods to and from warehouses.

Hardware Importers.—Sao Paulo has nineteen hardware importers, all handling varied lines of hardware merchandise and machinery. They have wide distribution to retailers and sell generally to other firms in the State and in adjoining States. Several of these importers are also large wholesalers.

Textile Mills.—There are all told about twenty-nine textile mills in the city. These mills vary in size, some being small and some large. All have a legitimate use for trucks. They will require vehicles of different capacity. They may require trucks for general use around the factory as well as the handling of raw and finished materials.

Sawmills.—Six sawmills are located within the city and there is much handling of logs and of the sawn lumber. There is delivery to lumber yards and for shipment by railway.

Importers of Provisions.—There are seven of these, all large concerns, and in addition are many smaller ones.

Shoe Factories.—The city has five factories given over to the manufacture of shoes. The leather has to be brought to the factory and deliveries of shoes to wholesale and retail local houses as well as to depots.

General Importers.—Six of these concerns, the largest in the field, have general use for trucks.

Leather Goods.—Four houses are devoted to this work.

Avenida Tiradentes, Sao Paulo, not the best, but one of the imporant residential streets of that city which is called the Chicago of Brazil. This avenue is a triple roadway and is an ideal street for motor traffic. There are many such in the city. Avenida de Paulista is the finest residential street of the city and motor trucks are not barred on the street. The city of Sao Paulo is located practically on the edge of the coffee country and all of the coffee shipped passes through the city by train

You see many streets like this in the towns and cities of the coffee areas in the State of Sao Paulo. This is a residential street in the city of Ribeirao Preto, a city of 25,000 in the heart of the coffee country. The streets are well paved, and everything is very clean. This city is distinguished as being the home of Santos Dumont, the Brazilian aviation hero. The city is destined to be a big coffee growing center. Recently the Ford dealer opened a selling branch there

In addition to these there are many other lines, as follows:

	No. Concerns		No. Concerns
Wholesale drugs	5	Meat packers	2
Electric goods	3	Lime maker	1
Foundries	3	Lead pipe factory	1
Glass factory	1	Campinas importers	3
Retail grocers	2	Screw factory	1
Contractors	2	Soap factory	2
Flour mills	3	Sugar mills	2
Hat factories	2	Wholesale stationery	2
Hop dealer	1	Rope factory	1
Jute mills	2	Silk factories	2
Newspapers	3	Seeds, etc.	3

To this list could be added scores of other concerns. No attention has been given to the hundreds of small shops who should be in the market for light delivery wagons of 500 or 800-lb. capacity. There are scores of bakeries, small grocers, etc. None of them is aware of the increased possibility of using light delivery wagons. They are inclined to look upon the light motor vehicle too much as merely an expense and an advertisement. They have not had it placed before them as an investment. They have not grasped the feature of extending business by the motor vehicle. They have not thought of improved service to customers because of faster and better delivery service.

Horse Labor Is Cheap

Horse labor is naturally cheap in the city. The grade of horseflesh is poor. The city, being in the tropics, is hot. The altitude assists in keeping the temperature lower, but in summer the heat is always present. Up to the present horseflesh has been considered very cheap, and the business houses have not carefully kept tab on what their horses really cost them.

There is a truck market in Sao Paulo. It is the best in Brazil at present. Perhaps in other years Rio will be greater but to-day it is not nearly so attractive as Sao Paulo. The city has plenty of good garages. There are plenty of places where you can get any kind of a good body built for a motor truck. In the city is one of the largest garages in South America. It has a body building department for passenger cars and trucks. Limousines and landaulets are made. It has every facility for the work. The U. S. A. truck maker will find no difficulty in getting any kind of truck body.

There are plenty of live automobile dealers in Sao Paulo. A few of them handle trucks. There should be no difficulty in making good truck selling connections.

How to Enter the Market

With regard to introducing trucks in the city the only way is to send one or two trucks there and demonstrate them. That is imperative. In addition there must be a big supply of spare parts carried in the city. You cannot sell vehicles without such stock of parts. You must have catalogs in Portuguese as well as lists of spare parts and instruction books in the same language. These should be ready when the trucks are shipped. You need them then and not a year later. Good exporting policies are needed in connection with truck sales.

Although the City of Rio de Janeiro is anything but an active motor truck market to-day there are notwithstanding good possibilities of selling trucks there when financial conditions improve and perhaps when the price of gasoline falls a little.

We made a careful estimate of the number of large industrial and other concerns in the city who are not using trucks but have a volume of business that would warrant the use of trucks, and their financial condition would also warrant their use. This list was made from the financial reports of the commercial department of the National City Bank of New York, which has a Rio office.

Without in any wise exhausting the field we found over 375 concerns that should be using motor trucks to-day. Some of these concerns are very strong financially, others not so strong have a big volume of business. For these firms motor trucks of all different load-carrying capacity are needed. Some will require fleets and others only individual vehicles.

Converting Passenger Cars

Although the sale of motor trucks practically ceased in Rio nearly 3 years ago there has been a growing movement by way of making old passenger cars into light delivery vehicles, and it is not uncommon to see a Renault or Benz converted into a 1500-lb. light delivery vehicle. This movement augurs favorably for a rapid development of the light delivery vehicle, because Rio merchants have just as much need for it as the merchants in any other city of nearly 1,000,000 population. Rio has really more need for motor vehicles than any city of its population, due to the hot weather. The city is located at water level and in the summer months of December, January and February it is very hot. In the Fall and Winter months you are quite comfortable in a palm beach suit.

In a short résumé of the concerns in the market for motor vehicles, no names will be given, but only a conception of the number of firms in different industries.

Meat Industry—As in all hot cities the question of meat delivery from the municipal slaughter houses is important. The animals are slaughtered in the morning and the meat must be in all butcher shops a few hours later. There is a good field for motor trucks here just as in Buenos Aires. In Rio are over 100 concerns in meat delivery trade who should be using motor vehicles of one type or another.

Seed Merchants—Of the firms engaged in the grain business ten at least should be using trucks. They have much

shipping as well as much delivery work to do.

Wholesale Textiles—At least twelve firms in this line would be warranted in using motor trucks. Brazil is a large textile industry, so far as South America is concerned.

Textile Factories—There are thirty of these factories within the city. All should be truck users. The raw products have to be taken to the factory, and the finished products delivered to depots, warehouses, etc. It is the general line of factory work.

Confectionery Houses—Over thirty houses in this line should use trucks. They will generally want light-capacity machines, although a few of them with large distribution will want the heavier-capacity vehicles.

Wholesale Houses—Rio is the big wholesale center for Brazil, its merchants selling to all of the twenty-one states, but not so generally in some lines as might be expected, due to such centers as Santos and Sao Paulo, Bahia, Para, Manaos, etc., buying direct and distributing to their own states.

There are ten wholesale grocers who could use trucks to advantage, twelve wholesale drug houses and many machinery houses.

Factories—Rio has quite an extensive and growing manufacturing colony, reference having already been made to its thirty textile factories. It has twelve shoe factories, six hat factories, five flour mills, three of which are very large, and two tanneries.

Business Houses—There are many business houses that should be in the truck market. They have to be convinced that their business warrants motor power. In this line are twenty furniture houses; you can add six important piano firms; add also twenty machinery houses, which do a big business in all kinds of machinery; then there are four firms in the mineral water trade; there are six concerns in the cigar and cigarette trade; you will find six concerns needing trucks for general milk distribution, four others in the hide-buying business; and a general line of others.

At the top is shown a very poor coffee plantation. The bushes are not as large as they should be and some of them have perished. You rarely see a single acre of land in the country that is level. It is all rolling and when motoring along the roads you have many good hill-climbs to contend with. It is this rolling nature that makes the land more suitable for motor truck use. It will not be difficult to build good roads in such a country. There will always be good natural drainage. Directly above is a view of the rolling coffee country in the center of the State of Sao Paulo. It is through this country that many U. S. A. motor trucks will be sold in the next 5 or 10 years. The white buildings on the hillside mark the home of a coffee plantation owner. Around his home he has all the necessary tanks for soaking the coffee and terraces on which it is afterward dried

Contracting Firms—Rio has the usual number of firms in cartage trade, but like other tropical cities, has hundreds of individuals who have only a poor cart and a still poorer horse or mule.

There are fifteen cartage houses who should be general users of motor transport. Their work embraces all possible lines. The city streets are generally good and conditions relatively favorable for the use of trucks.

The city has eight building construction firms, each having the usual needs for trucks; add to this two firms specially engaged in street pavement and other city improvement lines; to these can be added several city departments.

Department Stores—Rio has twelve department stores that should be buyers of trucks and deliveries. To this can be added twelve retail hardware houses. You may also add six hotels who have use for motor buses and baggage wagons.

Rio as a city should be a big truck field. This field may not be so large as its population would lead you at first thought to imagine. This is due to the high percentage of African population. Also do not forget that the city is surrounded by mountains without any roads leading to outlying cities. You cannot possibly go 40 miles out of the city. Rio, while fortunate in enjoying perhaps the finest scenic location of any city in the world, is not surrounded with a rich farming or mineral land that would call for a general use of trucks leading into the fertile areas around the city. Sao Paulo occupies a great advantage in this respect in that the coffee land lies all to the north and west of it. The trucks for Rio are for use only within the boundaries of the city.

(*To Be Continued*)

Turpentine as Fuel

The English market has been flooded with gasoline substitutes, since the use of gasoline has been restricted by law. *The Engineer* (London) states that nearly all these substitutes consist of kerosene with a small admixture of some other substance, and need an admixture of an equal quantity of gasoline before they are readily usable. It is also stated that some "substitutes" are mixtures of kerosene with turpentine. It would be interesting to know the exact function of the latter liquid.

Show Spaces Allotted

New York Gains Fourteen Exhibitors Over Car Manufacturers at New York and

NEW YORK CITY, Oct. 5.—Ninety-eight automobile concerns, including five manufacturers of electrics, were allotted space at the New York show at to-day's meeting of the National Automobile Chamber of Commerce. This compares with eighty-four last year. Space was given to ninety-four automobile concerns for the Chicago show, as against ninety last year. Every foot of available floor space in Grand Central Palace has been taken, several of the new companies being placed on the fourth floor with the accessory exhibits. As at the New York show, space at Chicago is limited on account of the large number of space allotments.

This meeting each year is the big get-together assembling of automobile makers, who are usually in attendance or represented by others prominent in the business activities of the companies. To-day's meeting was the largest in point of attendance in the history of the Chamber, there being more than 100 automobile manufacturers represented. Charles Clifton, president of the organization, presided at the general meeting in the morning, and S. A. Miles, manager of the shows, came down from his summer home at Christmas Cove, Me., to preside at the space allotments.

That the meeting was a representative one is manifested by the list of those in attendance, including John N. Willys, Hugh Chalmers, W. E. Metzger, A. P. Chalfant, H. H. Franklin, W. C. Leland, Elwood Haynes, E. J. Moon, W. T. White, W. H. Van Dervoort, H. M. and F. Jewett, L. H. Kittredge, Charles Clifton, C. C. Hanch, C. W. Churchill and F. C. Chandler.

Overland in First Position

Willys-Overland, as in the past 3 years, again had the honor of selecting the first position, on account of having been the leader in the volume of business for the year. Following came Buick, Studebaker, Dodge and Maxwell, Cadillac, Chevrolet, Chalmers, Hudson, Packard, Reo, Oakland, Saxon, Hupp, Chandler and Olds. Others up in the drawing were Paige, Mitchell, Haynes, Pierce, Franklin, Nash, Cole, Velie and Stearns.

Among 98 Car Makers

Last Year and Chicago Four—Five Electric Six at Chicago—Record Attendance

Several well-known cars will not exhibit at the national shows this year, among these being Locomobile and White. Such cars as the Monitor, Champion, Farmack, Gadabout, Trumbull, Lescina, Fergus, Remington, S. G. V. and S. J. R. will also be missed from the list of exhibitors. White and Locomobile will be on exhibition in January at the importers' salon at the Hotel Astor, this city. The coming shows, however, will be featured with a large number of new cars, which have never before been exhibited. These include at the New York show: Monroe, Columbia Electric, Detroiter, Liberty, Bour-Davis, Ben Hur, Elgin, Drexel, American, Princess, Dey, Kent, Doble, Jordan, Emerson, Harroun, Monitor, Dixie and Roamer. The Chicago show will list such new cars as Stephens, Emerson, Dixie, Classic, Harroun, Drexel, Pan-American, American, Ben Hur, Liberty, Columbia, Monroe and H. A. L.

Changes in Spaces Allotted

There will be several space changes this year at New York. Of course, Overland, Buick, Studebaker and Maxwell will retain last year's spaces. Others on the first floor this year are King, Stearns, Olds, Paige, Mitchell, Winton, Pullman, Pierce, National, Nash, Allen, Grant, Saxon, Hupp, Franklin, Chandler, Haynes, Reo, Packard, Oakland, Hudson, Chalmers, Cadillac, Kissel, Velie and Cole.

At Chicago, as at New York, Overland, Buick and Studebaker have retained last year's spaces on the Coliseum main floor. Other changes in placement of spaces have taken place. Maxwell has moved along the cross aisle, next to the Overland. Chevrolet has moved across the aisle in a similar position in the space nearest the entrance. Others on the main floor are Scripps-Booth, Apperson, National, Dort, Grant, Pullman, Paige, Haynes, Saxon, Chalmers, Reo, Packard, Oakland, Dodge, Franklin, Velie, Winton, Chandler, Pierce, Olds, Cadillac, King, Hudson, Nash, Hupp, Kissel, Briscoe, Allen, Case, Mitchell, Marmon, Auburn, Moon, Stutz, Inter-State, Cole, Stearns, Fiat, Mercer, Regal, Jackson and Empire.

Gravity Does Not Mean Power

Bureau of Mines Head Reports That Experiments Show Less Than 2 Per Cent Difference in Power Between 74 and 60-Deg. Gasoline

GRAVITY does not of itself furnish a satisfactory basis for buying gasoline, Van. H. Manning, director of the Bureau of Mines, told the Retail Merchants' Assn. of Washington, D. C., in an address delivered Oct. 4. The association has launched a campaign for purity in gasoline and Mr. Manning's report that tests made by his department showed a difference in power of less than 2 per cent between gasoline of 74-deg., and 60-deg. gravity prefaced his statement to the effect that, under proper engine conditions, power is not a matter of the gasoline used. Mr. Manning pointed out how the co-operation of automobile engineers has made the use of lower grade fuels practicable in the cars of to-day and then explained how the end point of gasoline had been increased by the refiners' use of heavier oils from 150 deg. Centigrade a year ago to 175 and 200 deg. Centigrade at the present time.

While our present gasoline supply is sufficient for only 27 to 30 years, without taking into consideration the probable yearly increase in the demand, Mr. Manning states that the remarkable development of the casing head gasoline industry during the past year gives promise that the coming years will bring into existence new methods of producing, increasing or utilizing the gasoline output so that the problems of the automobile fuel situation will be gradually worked out to a satisfactory solution. Mr. Manning's address follows:

"The Bureau of Mines is in entire sympathy with the campaign for purity in gasoline, and wishes to be of aid to the entire country in this important matter.

"We are to-day facing a serious condition in the petroleum industry. We have probably reached the summit of our crude oil production in this country. According to the United States Geological Survey, our future supply of petroleum is only sufficient to last us from 27 to 30 years at the present rate of consumption. This does not take into consideration any increasing demand as the years go by. In order to supply the fuel for the future automobiles, it will be necessary to make better use of our crude oil production in the future than we have in the past.

Production Is Inadequate

"In discussing the various problems involved, we must bear in mind that while the demand is steadily increasing, the production of crude oil, which is the raw source of the gasoline, is remaining approximately stationary, if it has not been declining in the past year. A year ago gasoline was selling at 11 cents a gallon and was a drug on the market, due to the tremendous production of gasoline-rich crude produced by the Cushing field in Oklahoma. This production, however, has declined from over 300,000 barrels of crude oil per day to less than 60,000 barrels per day.

"The Cushing crude contains from 25 to 30 per cent of gasoline. The new production which has compensated for the decline in the Cushing production, contains but from 15 to 17 per cent of gasoline. Notwithstanding the decline in the production of gasoline, the demand has steadily increased, due primarily to the increased use of the automobile. On Jan. 1, 1916, there were two and a quarter million automobiles in use in the United States. It is estimated by the automobile manufacturers that there will be in excess of 3,250,000 in use by January, 1917, and by January, 1918, there will be in excess of 4,500,000 automobiles in use. These figures are in addition to the increased use of motor trucks, farm tractors, stationary gasoline engines, motor boats, etc.

Automobile Engineers Help

"This increasing demand for gasoline has been met partly by the automobile engineers and refiners. The automobile engineers have improved their automobile engines and carbureters, making it possible to use heavier fuels in the automobile of to-day, which would have been impracticable a year or 2 years ago. The refiners, taking advantage of the work of the automobile engineers, have been able to use heavier oils for gasoline, thereby increasing the percentage of gasoline obtainable from the given amount of crude oil. This has resulted in increasing the end point from 150 deg. C., the end point of a year ago, up to an end point of 175 deg. to 200 deg. C., the end point of to-day.

"The end point is a term used in distillation of gasoline and is usually considered to be the temperature at which 95 per cent of the gasoline will distill off if distilled in a proper flask at the proper rate. Recently the Bureau of Mines purchased four samples of gasoline sold in the District of Columbia. These gasolines were analyzed and the end point determined in each instance. The gravity of one was 64.8. The gravities of the other three samples ranged from 61.5 to 62. The end point of the first sample was 210 deg. C. The end point of the other three samples was 175 deg. The high end point of the first sample, together with its high specific gravity indicates that this is a blended gasoline. This is further borne out by the analysis, which indicates that 21 per cent is distilled over under 75 deg., whereas less than 10 per cent on the other three samples is distilled over at this same temperature. This larger proportion of light products, which is responsible for the high gravity, indicates that casing head gasoline has been blended with heavy distillate, because the end point of this gasoline is 210 deg., as against 175 deg. for the other three gasolines analyzed. It is possible that this blended gasoline might prove satisfactory in some automobile engines.

"The end point is important because it is a measure of the readiness of the gasoline to vaporize, which is necessary and desirable information to have in selecting suitable fuel for gasoline engines. As a result, the refiners have been able to supply a lower grade fuel, which is now adaptable to the improved automobile engine. This, of course, automatically has a tendency to keep the price of gasoline down, as it can readily be seen that if the standard of quality is higher, the supply would be more limited and higher in price.

Old Cars Suffer

"This will probably explain some of the difficulties that the people are having with the character of the fuel used in their automobiles at the present time, particularly if the automobile is of a design of 2 or more years ago, not having the improved engine and carbureter design, it is not equipped to use the present-day low grade of fuel.

"Refiners are co-operating along another line to the same end, namely, to increase the amount of gasoline and at the same time to keep the price down to a reasonable basis, by

means of cracking kerosenes and heavier oils, thereby converting a certain proportion of the crude oil which was not formerly utilized for that purpose into gasoline. Last year there was produced by cracking processes approximately 2,000,000 bbls. of gasoline. This year it is estimated that there will be produced more than 5,000,000 bbls. of gasoline by cracking processes. This is all the more striking when it is considered that these 5,000,000 barrels of gasoline were made from oils which in the past did not enter into the making of gasoline, and indicates the possibilities of the present production of crude oil to supply the future requirements of the automobile.

"These are some of the problems that have to be taken into consideration in any specifications that are drawn up. We want to be sure as nearly as we can that we get a grade of gasoline that will be satisfactory for our needs; then we have to be sure that it is of such a grade that can be supplied by the refiners at a reasonable price. Unless the specifications do take these factors into consideration, they may result in restricting the supply and making the prices exorbitantly high, and also may deprive many people of the pleasure of owning an automobile by making the price of fuel prohibitive. With proper development of the cracking processes, and the co-operation of the automobile engineer, there is no reason why a suitable fuel should not be available for years to come and at a reasonable price.

Future Not Threatening

"The Bureau of Mines has for a number of years appreciated the seriousness of the motor fuel problem; in fact, long before the sharp increase in prices of gasoline, this bureau was aware of the conditions, and realized that this increase in prices would follow. It was at that time the bureau began a serious investigation of this entire problem. The special investigation bearing directly on the quality of gasoline was begun 8 months ago and is being continued to-day. Samples of gasoline were purchased in the open market in all parts of the country (and not from refiners), and were analyzed by the bureau's engineers, and engine tests were also run on the representative grades of gasoline. The results to date are contained in a publication to be issued in the near future by the Bureau of Mines. There is also in course of publication, and nearly completed, a report on gasoline specifications, which has taken into consideration the available supply, increasing demand and the protection of the public, as well as fair treatment to the refining industry—all with the purpose of assuring a future supply of gasoline to the public at the most reasonable prices.

Gravity Does Not Determine Power

"One of the results that may prove startling to the public is that the gravity of the gasoline does not of itself necessarily mean a satisfactory basis for the purchase of gasoline. Engine tests were run by the bureau on gasoline having a gravity of from 74 deg. to 60 deg. The net result of these tests showed a difference in power developed of less than 2 per cent between gasolines of 74 deg. gravity and gasolines of 60 deg. gravity. This is all the more remarkable when it is considered that 74 gravity gasoline is selling at 31 cents per gallon, while the 60 deg. gravity gasoline can be purchased at 22 cents per gallon.

"It is probable that the 60 gravity gasoline, which can be purchased for 9 cents less a gallon, can be used in the automobile with the same satisfaction as the 74 deg. gravity gasoline.

"All gasolines can, under properly regulated engine conditions, be made to develop quantities of power which are not greatly different. This result was obtained from experimental work in our laboratories in Pittsburgh, and indicates that the claim made by many refineries for the power-producing qualities of their gasoline are largely without foundation. It does not necessarily follow that all gasolines are equally good, but it is certain that exaggerated claims are made for the number of miles per gallon. The possible element of superiority undoubtedly lies in the quality some products have of giving maximum efficiency over a wider range of engine conditions. The fact of importance is, therefore, that if the user of gasoline takes sufficient care of his engine, he can obtain almost as good results from a cheap gasoline as from an expensive, high-test product, as the power developed under like conditions varies in our experiments.

Casing-Head Gasoline

"Recently, owing to the remarkable development of the casing-head gasoline industry, that is, obtaining gasoline from natural gas, there has been obtained a product called 'blended' gasoline. The casing-head gasoline as derived from natural gas is too volatile to be used directly. It is therefore mixed with oil just a little lighter than kerosene but heavier than gasoline. Such a blended gasoline may be of any gravity desired by the manufacturer, but is naturally different in composition and properties from the straight refinery product which it may chance to resemble in gravity only. This is due to the fact that it is generally composed of more of both of the heavier and lighter oils than gasoline made by the ordinary processes. On account of the larger proportion of light oil, it is possible to use a correspondingly large proportion of heavy oil and still have an average gravity the same as ordinary gasoline, but which may act very differently in an engine on account of the large portion of heavy oil contained in the blended product.

"This is not intended to discourage the use or manufacture of casing-head gasoline. If the casing-head gasoline is blended with the proper oils, that is, oils that are not too heavy, it can be used satisfactorily in an automobile engine. Casing-head gasoline is an important addition to our fuel oil resources, the production amounting to approximately 5 per cent of the total production of gasoline this year.

Preparing Gasoline Specifications

"The Bureau of Mines is now preparing gasoline specifications for the General Supply Committee of the Federal Government, which will undoubtedly be of interest to all users of gasoline. These specifications should be issued within the next 90 days.

"The Bureau of Mines has a complete testing laboratory, equipped with engines and other necessary apparatus, with which it will be possible to make power tests on gasoline, as well as on other internal combustion engine fuels. The results of these tests will be available to the general public, and will be of the utmost importance in clearing up the difficulties with which it is confronted to-day.

"In conclusion, I wish to emphasize the necessity of bearing in mind the following consideration in our efforts to obtain purity in gasoline. We must keep before us the fact that there should be the greatest possible use of the raw materials consistent with economic results. For instance, no specifications should be drawn up which would exclude certain materials now being used satisfactorily, for if eliminated, this would correspondingly restrict the supply and automatically increase the price. This of course, is not desirable. The bureau is exceedingly anxious that all the available resources for the making of gasoline be used to their greatest extent, and it is also interested in the encouragement of further economy in the design of the automobile engine. Any specifications that would restrict the use of some of the low grade oil resources would at once stop any further efforts toward improvement in engine design. At the same time, the bureau is interested in seeing that the public obtains a satisfactory fuel."

Ford Melting Pot, where graduates received diplomas on Oct. 1

Ford's Melting Pot

Company's English School Cuts Accidents 54% — Eliminates Interpreters

WHEN the Ford English School, commonly known as the Ford Melting Pot, graduated 250 of its pupils on Oct. 1, it marked the third graduation class since the opening of the school in 1914 and witnessed the disappearance of interpreters with a decrease of 54 per cent in the number of accidents in the production department.

Beginning with twenty pupils and one teacher, the school, has grown until it includes 2720 members with 163 instructors.

The instructors are all employees of the factory, composed of foremen, machine operators, clerks and workmen who, voluntarily and without compensation, give their spare time to this work. Lessons are similar to the Berlitz system.

Many types come to the classes. There is the type which has a good education in his native tongue but knows no English; and the type that has a fair education in the mother-tongue and knows a few disconnected English words, usually slang. Then there is the group which possesses little if any education, either native or English. The first and second classes progress rapidly. Some of the men are able to read, write and speak English with a fair degree of correctness at the end of 3 months, though the average time for completing the course has been found to require 6 months. One class, set aside by itself, is very slow, completing but ten lessons in 10 months.

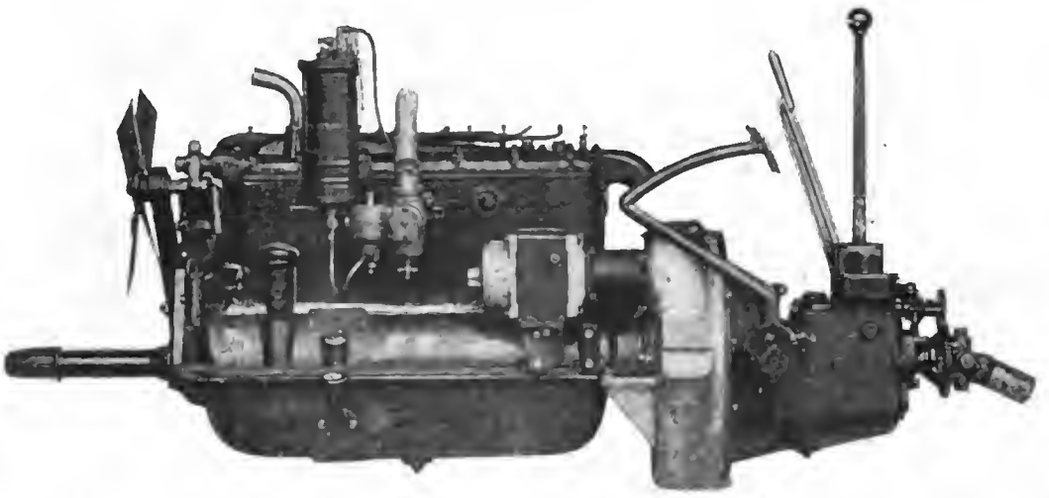
The usual class program consists of 45 min. in the morning and 1½ hr. in the afternoon so arranged because the men work in three shifts of 8 hr. each. The course consists of sixty-eight lessons taught in 34 weeks and includes 25 min. of oral training, 10 min. of reading exercises, 15 min. of writing lesson and 15 min. of review in each lesson. The first thing a man is taught to say is, "I am a good American," and a few minutes is devoted each day toward teaching the classes a few lines of the song "America." Attendance to the school is compulsory and men who refuse to attend are threatened by a short layoff. While the compulsion seems harsh to some, the Ford company believes that the end justifies the means and it is actually making more efficient, intelligent and valuable workmen by the plan already outlined.

The Ford Company also gives two other courses of study for its employees. They are the student course and the tool-making course. The latter includes a 2 years' study and was established to meet the scarcity of skilled mechanics. The members of the classes are required to have a previous knowledge of higher mathematics.

The student course qualifies employees for salesmanship and mechanical work. The more intelligent men only are selected and are thus built for the higher positions. They attend the school for a year and are constantly shifted from one department to another in the factory and offices and can later be used for branch managers or department heads. The company also places fifty Indians from the Carlisle College in this class every year. The college offers the Ford opportunity to its students who regard it as an incentive and strive to be among the fifty. Dean Marquis states that the Indians are among the best workmen in the institution.

Ford English school pupils and graduating class, sthered sround the Melting Pot on graduation day, Oct. 1, listening to an address by Dr. M. F. Rice

Lexington in Two Six-Cylinder Chassis



Six-cylinder Continental power plant used in the new Lexington sixes, showing high mounting of carbureter with Stewart vacuum fuel feed tank. Starter mounting is also shown. Note gear for speedometer drive in rear of three-speed gearbox and adjustment for pedal on lower end

Many Body Styles for Minute Man and Thoroughbred—Multiple Exhaust Continued

THE aim of the maker of the Lexington Sixes, the Lexington-Howard Co., Connersville, Ind., is to produce cars of high finish and excellent detail equipment. The chassis are made up of well known units, but it is the manufacturer's claim that the design has an unusual coherence for an assembly proposition, the reason being that several of the parts factories whence the Lexington company obtains its supplies are owned and operated by the same business heads.

Two Chassis—Many Bodies

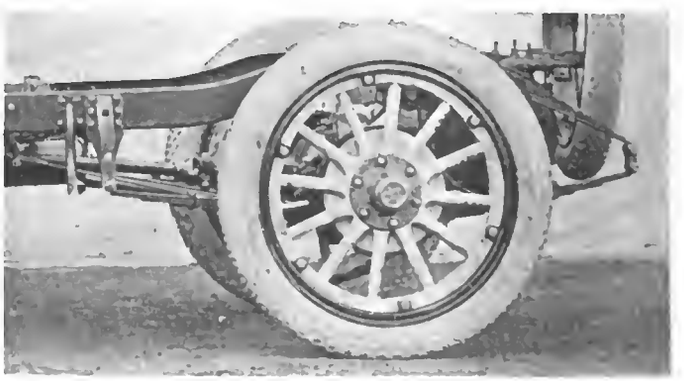
There are two different chassis, on which a fairly wide range of body styles are mounted. The smaller is known as the Minute Man six and sells for $1,185 and the larger is termed the Thoroughbred, costing $2,875. Both have Continental engines, the smaller 3¼ by 4½ in. and the larger 4⅛ by 5¼ in. but there is a special feature on these motors for which it is claimed that it gives a large increase in the power. This is the Moore multiple exhaust manifold, used in conjunction with two mufflers as may be seen in the chassis plan view. Briefly, this Moore system consists of an exhaust manifold so divided that the exhaust from one cylinder has no possibility of interference with that of the next. On the contrary, the escaping charge from one cylinder is believed to exercise some suction on the next. In six-cylinder engines where there is always one exhaust valve open and two open together at very frequent intervals interference most certainly does take place with the conventional exhaust system and it is a remarkable thing that the Moore system or some other device with a similar aim is practically never used except on the Lexington and one or two foreign cars.

In other respects the engines are typical Continental products. The two sizes differ a little in detail, but not very much, both being pump cooled. Lexington equips the larger with two separate ignition systems and twelve spark plugs, the smaller having only one distributer, but this is built into the engine and is not a part of the generator. The electric generator is located on the water pump side of the engine, and is driven by a quick detachable coupling specially designed to give soundless operation.

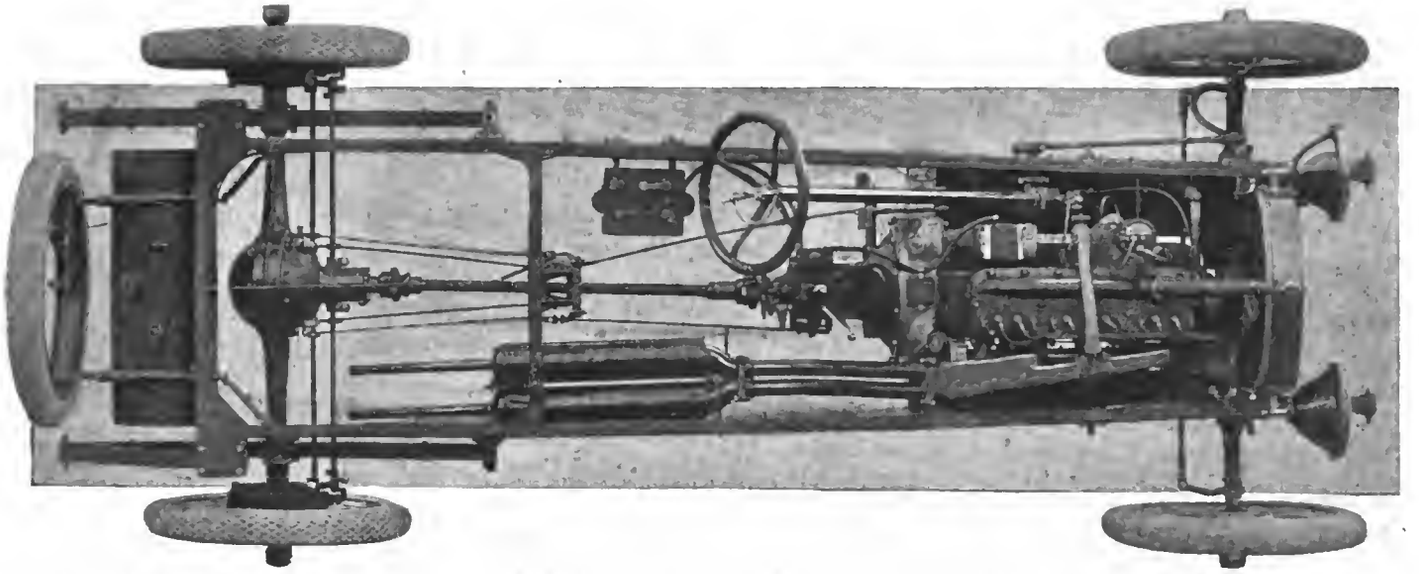
Force-Feed Oiling to Bearings

Each of the three main bearings of either engine gets its supply of oil forced direct from the pump, dip troughs being filled by the same pump for supplying the connecting-rod bearings and other parts of the motor by splash. The carbureters are mounted high, with gas passages as short as possible between throttle and cylinder, the fuel being fed by vacuum system in conjunction with a 22-gal. tank at the rear end of the main frame. Care has been taken to provide indicators so that the driver can see at a glance how his engine accessories are operating. Thus the oil system is provided with a large pressure gage which is set in the cowlboard, and the electrical outfit includes a cowlboard ammeter showing whether the battery is being charged or not, and also measuring the discharge rate when the battery is used with the car standing and engine stopped.

Driver's compartment of new Lexington, showing divided front seats, ample leg-room and control members



Rear of chassis, showing drop of forward spring end



Lexington Minute Man six chassis, showing dual exhaust system with separate outlet from each cylinder block and two mufflers. This view also shows carbureter hot air intake, storage battery mounting, rear fuel tank and spare tire carrier

Each of the two cars has a three-speed transmission bnt it should be noticed that the more powerful car has a substantially heavier gearbox with wider gears of bigger pitch, in proper proportion to the higher engine power. The clutches are different, as the Minute Man has a multiple dry disk pattern and the Thoroughbred a special cone clutch of Lexington design which has the leather face hand ground to a fine surface that fits accnrately in the flywheel. The leather has twelve spring inserts beneath the face.

Torque and drive stresses are taken care of by the three-quarter elliptical rear springs, the propeller shafts being fitted with universals at both ends. Extra large diameter tubes are used for the propeller shafts to guard against whipping when running fast. The rear springs are 50 in. long and underhung beneath the axle, vanadium steel being used throughout for spring work.

Frame Is Unusually Rigid

Another place where exceptional material is employed is in the frame and the manufacturer makes a special point of drilling the holes in the side rails and applying the rivets so that a particularly good job is made of the frame altogether. All the different brackets are hot-riveted, and at several points Lexington uses more rivets for a particular piece than is the conventional practice this, of course, assisting rigidity and preventing the production of creaks. The front and rear axles are conventional in type except that the former is carefully set to a give a caster action to the steering. Final drive is, of course by spiral bevel.

On the smaller chassis four body styles are available. The five-passenger open touring car which costs $1,185 is finished in dark green, with wheels in cream color and chassis, with fenders, black. The top and side curtains are black leatherette, and the top boot of the same material. The top clips to the windshield, which is set with a slight rake. The equipment is more than nsually complete for it includes a tire pump with accurate gage, a trouble lamp, double-bnlb headlamps and motor-driven electric horn as well as tire carrier and rim license brackets, etc.

A Convertible Touring Model

Alternative bodies on this chassis inclnde a convertible type touring car from which the windows can be detached individually. This body has been worked ont so that the top really fits the body beneath, the lines harmonizing as they do in a fully enclosed body. The color scheme is the same as for the open touring car and the equipment also. This convertible sells for $1,350.

There is an open roadster and a convertible roadster, following the scheme of the five-passenger cars, the former costing $1,185 and the latter $1,350, just as the touring car. The equipment is identical except that the roadsters are finished in a deep wine color instead of the dark green. All these bodies mount on the same 116-in. wheelbase chassis and wood wheels with 32 by 4-in. tires, non-skid rear, are standard.

Clubster with Small Tonnean

On the larger car there are two standard bodies, a seven-passenger tonring and a four-passenger close coupled design called the clubster. The clubster is not a clover-leaf, but is a small tonneau job with only two doors, these opening into the rear compartment. The driver and front passenger reach their seats by stepping forward in the aisle. There is a very roomy cnpboard in the rear end of this body which provides ample room for tools, inner tubes, etc. The spare tire at the rear acts as a frame for the door to this cupboard so that it is readily accessible at all times.

The seven-passenger also has divided front seats. The wheelbases differ, the touring car being 144 in. and the clubster 130 in. Both have five 36 by 4½-in. cord tires included in their equipment and both cars are finished in almost any color at customer's option this extending to the npholstery even. The touring car costs $2,875 and the clubster $2,675, inclusive of everything.

Lexington Minute Man six-cylinder five-passenger selling at $1,185 with full equipment. Note divided front seats and Boyce Moto-Meter

N. S. W. Car Imports Increase 138%

United States Ships Over One-Half of Bodies and Chassis—Rubber Imports Increase Over 300 Per Cent—Canada, Italy and France Gain — Country Is Prosperous But War Taxes Make Low-Priced Cars Most Popular

SYDNEY, AUSTRALIA, Sept. 15—The automobile buying power of New South Wales, Australia, has not been lowered, despite the war. This state, which is one of the leading commonwealths of Australia, made a large increase in its automobile purchases during the first half of 1916. During that period, automobile chassis valued at $1,757,140, bodies valued at $454,230, and rubber articles valued at $1,676,100 were imported. The value of the chassis and bodies alone increased 138 per cent while that of the rubber articles including automobile tires and tubes, increased over 300 per cent.

United States Leads

That the United States has established a good foothold in its automobile trade in that state is indicated by the importation of $1,513,055 worth of American bodies and chassis during the first 6 months of 1916, or over one-half of the total automobile imports.

The United States also came to the fore during the first part of 1916 as a shipper of rubber goods, of which automobile tires and tubes constituted one of the leading items. Rubber exports to New South Wales from the United States increased nearly 1000 per cent, or from $132,585 to $1,302,530.

Low-Priced Cars in Demand

Despite the fact that body building in Australia is an important industry, this state increased its body imports nearly 300 per cent during the first half of 1916. The United States also led all other countries, its shipments totaling $357,100 out of a total importation of $454,230 in bodies. This is probably due to the scarcity of labor in the factories on account of the war.

New South Wales has been a market for low-price automobiles, especially in the country districts. With this class of population purchasing practically 80 per cent of the cars, it is not surprising that the low-priced and medium-priced types should lead.

The demand for high-priced cars is small because of the high taxation on individuals. Added to general taxes that have

Comparative Return Showing the Imports of Automobile Chassis, Bodies and Rubber Articles, into the State of New South Wales, for the First 6 Months of 1915 and 1916 Respectively.

the effect of raising the cost of living, there are special automobile imposts varying from $10 to $50 according to size. In the truck field things are particularly bright, since the large number of users who have lost their vehicles to the government will buy anything capable of doing the work.

Country Is Prosperous

New South Wales has always been the leading automobile buying state in Australia on account of its exceptionally large farming and pasturage districts.

Despite the war, business in that state, in fact in the whole of Australia, remains prosperous and people are purchasing freely. That the Australian government is doing all in its power to better export conditions is manifested in the recent purchase of cargo steamers on account of excessive freight rates and the general difficulties in obtaining merchandise.

Canada, the United Kingdom, Italy and France ranked respectively next to the United States in the value of chassis shipments. Of the four, only Canada and Italy showed increases over 1915 shipments. Canada, which ranked second, exported $273,775 worth of chassis in the first half of this year, as compared with $89,945 in the first half of 1915.

U. S. Shipments $1,205,730

The accompanying table shows some interesting figures. Though shipments of chassis from the United Kingdom totaled $204,470, only $140,910 worth of automobiles actually were manufactured in that country. The total shipment of automobiles from the United States was valued at $1,205,730, while the value of the cars manufactured there and sent to New South Wales was $1,155,955. Canadian shipments to New South Wales were less than actually made for that country. Canada shipped $216,045 worth of automobiles direct to New South Wales, while the value of the cars made in that country and received in New South Wales was $273,775, which brings out the fact that many Canadian cars are either being shipped from the United States or are being sent to the United Kingdom and thence to their destination.

Paint Poles White at Danger Points

WHILE all kinds of efforts are being put forth by State and county highway officials to minimize the dangers of night driving to automobilists due to curves, bridges and other road conditions, one of the simplest safety measures possible seems to have been overlooked. If telegraph and telephone poles in the vicinity of the point of danger were painted white, drivers would recognize their significance at once, and, in fact, could hardly help noticing them so that they would be put on their guard. F. W. Pelton, publicity manager of the Mitchell Motors Co., Inc., Racine, Wis., is responsible for this suggestion to the highway commissions, his idea being that the ten poles on each side of the danger point should be painted about 10 ft. from the ground for about a 5-ft. strip of white with a red band about 1 ft. wide in the center.

At railroad crossings, Mr. Pelton points out, railroad officials would be glad to co-operate, for many railroad crossings are so obscured by buildings, trees or other obstacles to vision that a car driver does not realize the nearness of danger until he is right upon it.

Disk Wheel of Great Simplicity

AT the plant of the Detroit Pressed Steel Co., Detroit, Mich., A. L. Putman has recently developed a steel disk wheel which has an extreme simplicity in combination with good appearance and ease of manufacture. Putman uses only a single disk, and has patented a special machine wherein the disk is rolled in such a way that it is thickest at the center where attachment to the hub is made, and thinnest at the edge, the section tapering as shown in the sectional cut.

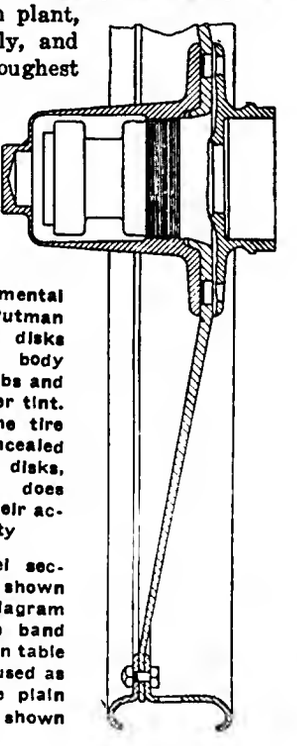
The outer edge of the disk can be riveted to any sort of felloe band to carry any kind of rim, and it is merely clamped between two plates on the hub, dowel pins being provided to take the drive for the rear wheels.

The outer shell of the hub is supposed to be made so that it can be unscrewed readily, and has some simple lock to keep it tight when holding the disk in place, this allowing the whole wheel to be detached as easily as any wire wheel.

The wheels are mounted on the car with the concave side outward, and it is noticeable that they have none of the clumsy look always possessed by disk wheels which stick outward at the center. The actual car has to be seen for it to be possible to realize how utterly different in appearance these wheels really are. Instead of looking heavy their real lightness is apparent at a glance.

It is reported that the Michelin company has lately developed a disk wheel in its French plant, which also uses a single disk only, and that this has proved equal to the roughest work in the war zone. The Putman wheel has been tried out on the roughest roads in Michigan without showing any trace of weakness.

In the experimental car with Putman wheels the disks are painted body color with hubs and rims in darker tint. Note that the tire valves are concealed behind the disks, though this does not hinder their accessibility



In the wheel section the hub shown is only a diagram and a felloe band for demountable rims can be used as easily as the plain clincher rim shown

The FORUM

Wants Greater Economy in Automobile Running Cost

By V. A. N.

IN these days when efficiency and economy are playing such an important role in manufacturing in general, and the automobile industry in particular, it seems to the layman quite incomprehensible that so little attention is being given to efficiency and economy in the finished product.

Efficiency and economy are largely synonymous. When we read descriptions of small bore, long stroke, high efficiency motors we naturally think of economy in operation, and when we read of conveyors shooting the parts around through the factory, each mechanic getting in his whack as the load passes, economy stares us in the face—until we behold the finished product; then what happens?

Consider for a moment in these days of advanced metallurgy, the cost of gasoline, tires, etc., the proposition of using a 2700 to 3000 lb. (or more) machine to haul five passengers over our highways more or less comfortably—adding in not a few instances a V-motor of eight to twelve cylinders to do the hauling. If that isn't a travesty on efficiency, what is it?

Is there any logical reason why we have not in the market to-day a well-made, comfortable, durable, accessible four-cylinder, 112 to 115-in. wheelbase, five-passenger car weighing ready for the road 2000 to 2300 lb. and selling for $1,200 to $1,500?

Franklin builds a real automobile weighing 2,289 lb., which is a delight to drive and ride in. Why is it that we have not the privilege of buying an equally durable and comfortable, efficient four-cylinder car of the water-cooled type?

Efficiency being so desirable in manufacturing, why not turn at least a little of it loose and head it toward the composition of the finished product?

Troubles with Kerosene and Water Cooling

By Harmon J. Kline

APPARENTLY the interest manifested during the past few months in the two-cycle type of motor has died out is so far as the discussion between the engineers is concerned. It seems to me that you were getting at the bottom of things, and if the various parties interested would do a little real work to find out where they stood instead of merely talking about their own inventions in particular, we would obtain some valuable information. The fundamental difficulties with the two-cycle motor have been bared and it needs some argument to disillusion ourselves of the fact that it has not been a very great success in the automobile field.

Any one who has had actual experience with kerosene engines, other than the semi-Diesel, will soon realize that even the best of vaporizers are not the final solution. One does not have to work on pure kerosene but the present motor fuel offers enough problems for the automobile engineer for the next few years.

It is impossible to obtain a fixed gas from kerosene at the temperatures available from the exhaust heat of the internal combustion engine as we know it. We may atomize the fuel and supply sufficient heat to keep it in the vapor form but it is not a fixed gas in that it will condense on coming in contact with a cooler surface. The latent heat of vaporization is about all we can hope to get. If there were more heat, it would merely expand the mixture and help to disassociate the fuel into other constituents, a thing not at all desirable owing to tarry deposits.

The present motor fuel contains from 25 to 40 per cent kerosene and it is this amount that is giving trouble to the man who must make the best of the situation. One does not have to look far to find that a great many motorists are having enough trouble starting and operating their motors in damp or cold weather to even think of using kerosene alone. It often takes some time to warm the motors up to the point where they will operate satisfactorily.

Air Cooling a Suggestion

Perhaps air cooling would make a decided difference, as has been proved in motorcycle practice where the engine is entirely exposed. The amount of metal involved is about equal in both the air- and water-cooled types but the latter has a body of water that must be raised to a temperature below the boiling point and having a specific heat much higher than that of cast iron or aluminum. However, to operate an engine on kerosene or even our low grade fuel, the operating temperatures are far below those at which the maximum efficiency may be obtained. The ultimate power developed, and pre-ignition, are practically the only limiting factors. These may be eliminated by careful design and internal air cooling, while extreme high speed is not desirable in motors where highest economy and durability are the controlling factors.

Present Fuel Troubles

The trouble found at present in the use of our so-called "motor fuel" is before the engine has reached its normal operating temperature. There are many, even dealers in cars, who have found that after 500 or 1000 miles' running they had more "oil" in the base of their engine than was originally put in. Many bearings have been burnt out as a result, and it doesn't seem like good advertising to boast of the mileage obtained per gallon of oil when often the public is paying a big price to do the same thing.

Heavy Fuel Possibilities

It must be evident to many of us that the four-cycle motor is not well suited to use fuels heavier than gasoline or motor fuel, in view of the present difficulties, unless some means are employed other than the kerosene carburetor and vaporizer. Of course, results may be obtained with special equipment in the hands of an expert and apparently satisfactory operation had after the engine warms up, but the rub is to obtain a motor that will give adequate service in the hands of the public. If the man who knows little of these matters is forced or wants to use kerosene in his car, it does not look like good business to sell him something not entirely satisfactory in service.

The matter of temperature control is important, but does not go far enough to give maximum economy and service. I think air cooling, if properly applied, would come closer to the mark than all the devices put on to make a satisfactory water-cooled job, at least in the motor car. I know of at least one prominent manufacturer who has discarded alumi-

num pistons for those of cast iron, mainly to obtain higher operating temperatures. The design of the piston was up to the best practice and long rods are used to reduce side pressure. I know of others who are having some trouble from pistons seizing as the speed is increased, though the clearance is large. Others are troubled with an excess of fuel in the crankcase, blown past the pistons. And yet the operating temperatures are not as high as to give maximum efficiency all the time and in some cases too high to give proper lubrication of pistons and even main bearings, the latter due to extreme speeds.

Invents Device To Keep Dust Out of Cylinders

By Dr. F. Strattner Orem

AS a subscriber I am writing for the information of Chas. E. Duryea relative to his comment on Mr. Schipper's article on U. S. trucks in Mexico, to the need of filters, to prevent dust entering the engine cylinders.

I have invented and have had in use for about 2½ years on a car that has made over 14,000 miles, a device that prevents dust entering the engine cylinders, does not lessen the amount of air the engine requires and does not need to be sent to the wash at all. A whisk broom used on the surface of the filtering material every 10,000 miles is advisable, but not always necessary. In this connection it may be stated that, due to keeping the road dust out of the engine cylinders, carbon deposits are practically nil.

Thinks Car Builders Do Not Provide Against Minor Noises

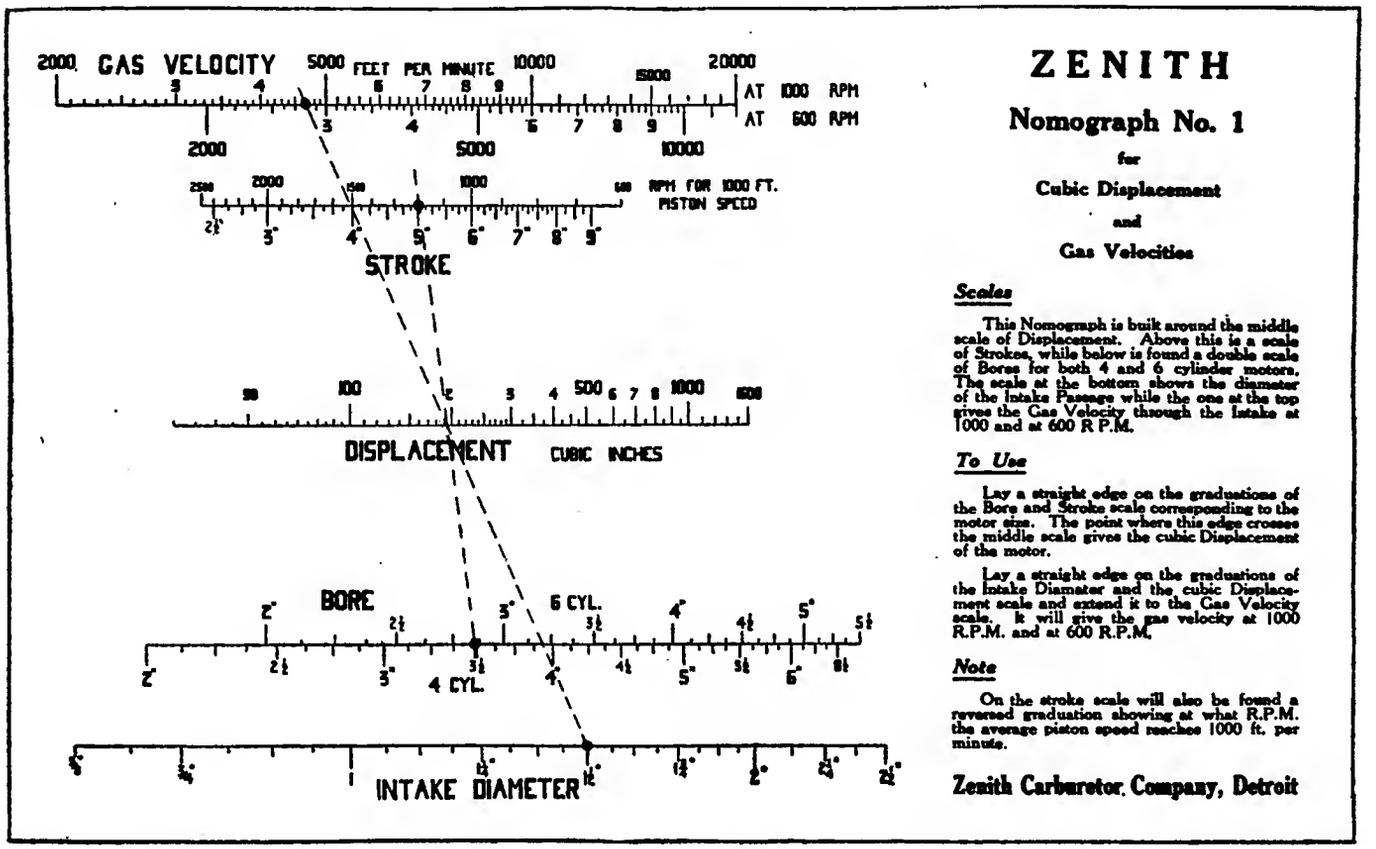
By M. K. Woodford

WHY do car manufacturers neglect to provide against the minor squeaks and rattles which develop after a new car has been run a few hundred miles? Frequently I have seen a beautiful high-priced car swaying gracefully and easily over a rough pavement or road without the slightest sound emanating from the engine or the transmission system, but a succession of viciously disagreeable and annoying squeaks and rattles radiating from almost every other part of its anatomy. These noises were all absolutely unnecessary and simply served to spoil the excellent impression given by the actual performance of the car.

It seems to me that a little attention on the part of the car maker to the sources and causes of these noises would enable him to provide against their development under what might be considered normal service. The most common causes of such noises are poorly mounted or lubricated springs, rattling doors, loosely-fitting floorboards, bad provisions for carrying tools and other loose equipment and defectively attached mud aprons, etc.

Some manufacturers, notably Nordyke & Marmon, have taken up this matter and have endeavored to provide against these noises by special points of design in the car, and other makers would find it to their lasting advantage and to the credit of the reputation of their cars to do something along the same line.

Zenith Nomograph for Displacement and Gas Velocities



The diagram reproduced above has been brought out by the Zenith Carburetor Co., Detroit, Mich., with the idea of rendering it possible to approximate quickly various quantities in connection with the displacement in cu. in., gas velocities of automobile engines, etc. The dotted lines illustrate the working out of these quantities in accordance with the directions given above when the engine under consideration has a 3½-in. bore and a 5-in. stroke, the intake diameter being 1⅛ in.

Running on Town Gas

Shortage of Gasoline Drives Omnibus Proprietors in England To Try Gas as Fuel—Essential Things To Be Observed in Engine Testing—British Patent Covers Device for Pre-Heating Fuel Going to Carbureter

By A. Ludlow Clayden

IN America many manufacturers use either natural gas or town gas for the preliminary testing of their engines, and any good gasoline engine will run well on gas, though it will not give the same power as on gasoline. The *Commercial Motor*, England, in a recent issue describes how a firm owning several omnibuses has tried to substitute gas for liquid fuel in running some local services in a small town in the British Midlands. The experiment appears to have been quite successful and is described as follows:

"Andrew Barton Bros., of Beeston, are as well known to the trade in the Midlands as Daimler or Leyland is to the industry as a whole. They are large garage proprietors, and run several useful omnibus services, besides, in more normal times, pleasure trips on chars-à-bancs.

"Recent troubles over gasoline supplies, and the necessity, for national purposes, of continuing their bus services, which mainly convey munition workers to and from their places of employment, caused the firm to cast about for other means of supplying power.

A Simple Bag Used

"That gas would serve as fuel they well knew. How to store it on the vehicles for use was the problem. At first a collapsible framework with canvas covering, built in the form of a bellows, was tried. Although this served the purpose, it was defective in practical application owing to the area it presented, in all directions, to the wind. The present style of reservoir, a simple bag, was tried with some misgiving, as it was feared that it would have a tendency to roll. As a matter of fact, the 'gasbag' is a most pronounced success. It gives to the wind, presenting a streamline form.

"This gasbag, a simply-made sack of canvas with rubber insertion, rendering it water and gastight, holds 450 cu. ft. It is roped or strapped to the roof of the chars-à-bancs, and is filled by coupling an inlet branch to the gas meter. The same branch serves for attachment of the flexible pipe conveying the gas to the engine. The fuel is conveyed to a point just above the engine throttle. An ordinary cock close to the engine controls the supply, and this is regulated by a lever directly coupled to the throttle-valve lever, so that the gas supply is increased or diminished in accordance with engine speed.

Many Advantages

"The advantages of gas as a fuel, used in this fashion, are many. It is clean; there is no waste by spilling; the shape of the bag gives an immediate indication of the remaining supply of fuel, while also serving as a perpetual check upon the relative efficiencies of different drivers; the engine gives off the same power, and can be made to run more slowly; it starts easier, and requires less lubricating oil owing to the absence of gasoline to wash it away. Moreover, judging by results, the actual engine economy must be considerable to judge by the small volume of gas consumed when the wagon is in the hands of a careful driver.

Short Mileage

"The disadvantage is, of course, the short mileage possible per charge of gas. Actual running costs, considering that of fuel alone, and leaving economies of oil, etc., out of the question, are strongly in favor of this fuel. Arrangements are being made so that the time occupied in filling each of the gasbags shall be 3 min.

"Barton Bros. pay 32 cents per 1000 cu. ft. of gas, being large users for industrial purposes. The mileage per 1000 varies largely with the efficiency per driver, but averages 30, the equivalent of 1 cent per mile. Calculating on a basis of 8 m.p.g. of gasoline—a conservative estimate with much stopping and starting — this means that, to compete, gasoline would have to be obtained at 8 cents per gallon, an impossibility nowadays.

"As concerning the weight of the receptacle, *it floats* when filled, and its cost—Barton Bros., Beeston, England, are arranging to sell them at $75 each."

Testing Scientifically

The Automobile Engineer, England, has devoted much space to tests and testing, and one of the most helpful articles which has appeared in recent years is given in a recent issue. This is written by W. Ferrier Brown and is intended to be a guide to those new to the work of testing gasoline motors. It outlines very clearly what the tester should observe and what he should record.

It is necessary to have some method of preserving and recording data. It need not be any particular system. In fact, an arrangement of one's own invention will probably give best satisfaction, because a system so built up will be perfectly familiar.

With engine test data certain items must be taken by direct test on the bench, or some similar test, and from these known items the others can be deduced. Also certain engine dimensions must be known.

Firstly, there are the data that must be taken from the engine by test. The values are taken at various engine revolutions for each item, and over the total range of the engine speed. These are:

(*a*) Brake-horse-power.

English bus equipped for running on uncompressed town gas

(*b*) Power required to drive engine, *i.e.*, the amount of power lost to friction in the engine.

(*c*) Fuel consumption and specific gravity of the fuel.

(*d*) Oil consumption.

The engine dimensions required are:

(*a*) Bore of cylinder.

(*b*) Stroke.

(*c*) Number of cylinders.

(*d*) Engine weight, complete with flywheel.

Under this heading might also be listed compression ratio.

From the preceding data the following can be calculated:

(*a*) Engine weight per b.h.p.

(*b*) B.H.P. per liter of cylinder capacity.

(*c*) Mechanical efficiency.

(*d*) Indicated thermal efficiency.

(*e*) Brake thermal efficiency.

(*f*) Torque.

(*g*) Mean effective pressure.

To illustrate the article, an engine of the following dimensions will be taken:

Bore, 85 mm.

Stroke, 130 mm.

Number of cylinders, four.

Engine weight, 530 lb.

This engine, then, has a cubic capacity of 2940 c.c.—that is, 2.94 liters. It may be preferable for some to have the engine dimensions in inches and the capacity in cubic inches or pints, but metric measure is easier to handle, especially if the bore and stroke are in metric. That, however, is a detail that can be made to suit.

Referring to Fig. 1, the curves of brake horsepower and friction horsepower are shown taken over a range of from 400 to 2000 r.p.m. The curve of b.h.p. can be taken by friction or water brake, or electric dynamometer, whereas, the curve of friction h.p. must be taken by an electric dynamometer, as the engine has to be driven. The power required to drive the engine is the friction h.p.

By adding the curves of brake horsepower and friction horsepower, the curve

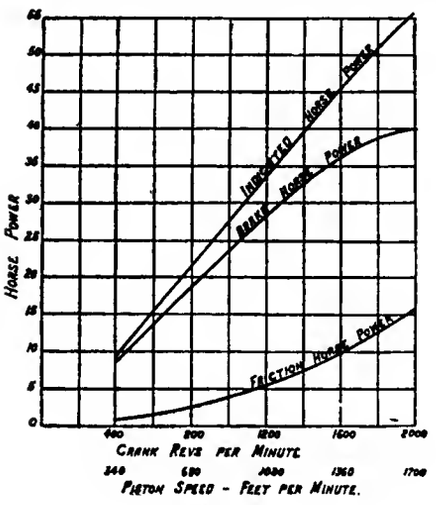


Fig. 1

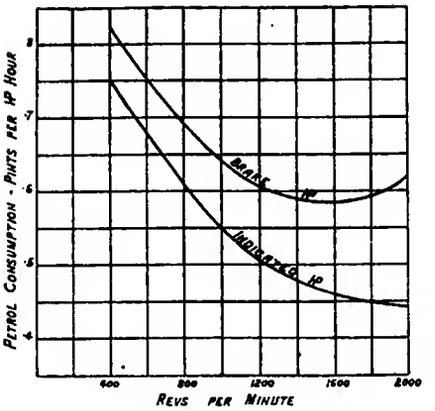

Fig. 2

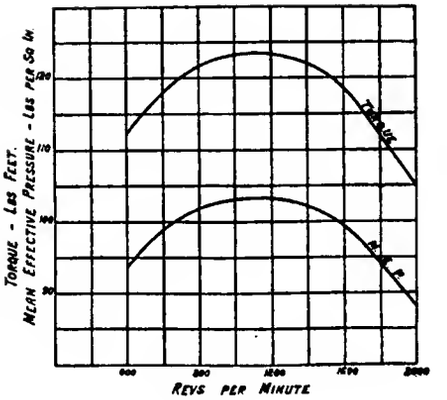

Fig. 3

of indicated horsepower can be constructed. The i.h.p. curve for the engine under consideration is shown in Fig. 1. This curve gives the amount of work performed in the engine cylinder. The curve of i.h.p. could also be constructed from an indicator diagram, but this method has not yet become anything like universal among manufacturers. These curves are plotted on a base of crank angles generally, but, as in this diagram, a second abscissa is given, namely, piston speed. This is a useful item to know, and, of course, varies directly as the engine revolutions.

The curves of fuel consumption (Fig. 2) are of first-rate importance, especially to the car user, because a low consumption means lower running costs. The two curves show the consumption in pints per b.h.p. hour and per i.h.p. hour respectively. As with the curve of b.h.p., the consumption must be taken by test at various engine speeds.

It may seem inconsistent to introduce pints or pounds when talking of fuel consumption after using metric measure for engine dimensions, yet it is customary, and one generally thinks of the values of various items in certain units and needs must have the values in those units to weigh up the relative performances and pronounce a judgment.

Fig. 3 shows curves of mean effective pressure (m.e.p.) in pounds per square inch of piston area, and torque, available at the crankshaft, in pounds at one foot radius. These items are functions of the b.h.p., and could be represented by one curve with two sets of values for m.e.p. and torque respectively.

The calculation is as follows:

(*a*) Mean Effective Pressure.

Let p = M.E.P. in lb. per sq. in.

$$p = \frac{\text{B.H.P.} \times 8262 \times 10^4}{\text{S}r k \text{D}^3}$$

where B.H.P. = Brake horsepower.

S = Stroke of engine in mm.

D = Diameter of cylinders in mm.

k = Total number of working strokes per revolution of the crankshaft.

r = Engine revolutions per minute.

(*b*) Torque.

Let T = Torque in lb. at one foot radius.

$$= \frac{\text{B.H.P.}}{r} \times 5252$$

In the foregoing formulæ the constants have been worked out to simplify the calculation.

Interesting and important are the curves of efficiencies as shown in Fig. 4. Four curves are given, viz., mechanical efficiency, brake thermal efficiency, indicated thermal efficiency, and available efficiency (as compared with the air standard).

Mechanical efficiency gives the percentage of useful work done at the crankshaft, that is, the b.h.p. as a percentage of the i.h.p. Thermal efficiency gives the useful work done, as a percentage of the total heat energy of the fuel.

One horsepower expressed in heat units is equal to 2545 British thermal units. Knowing the fuel consumption of the engine we can at once calculate the brake thermal efficiency. For general calculation, the heat value of one pound of gasoline of 0.720 specific gravity may be taken as 19,000 B.Th. units, unless, of course, specific values are stated. This will give 17,100 B.Th. units per pint.

Similarly, the curve of indicated thermal efficiency can be constructed, basing the calculation on the fuel per indicated horsepower.

In 1903 the Institution of Civil Engineers formed a committee to settle a basis of comparison for internal combustion engines. This committee recommended what is known as the "Air Standard Efficiency." The "air standard" gives the theoretical maximum thermal efficiency for internal combustion engines working on the four-stroke cycle.

Values are obtained from the formulæ:

$$\text{A.S. efficiency} = 1 - \left(\frac{\text{I}}{r}\right)^{0.4}$$

Where r = compression ratio.

$$= \frac{\text{Y} + v}{v}$$

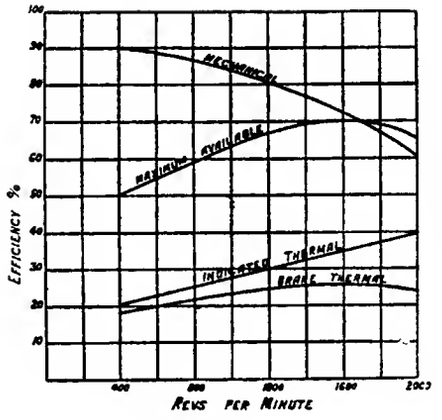

Fig. 4

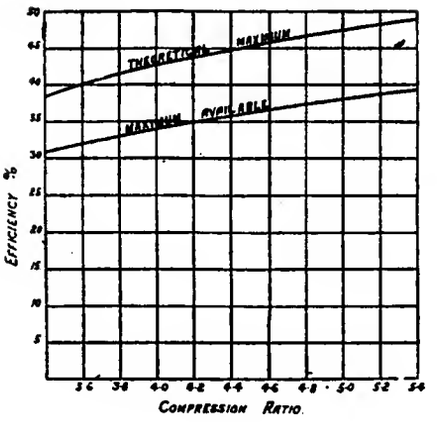

Fig. 5

V = volume swept by piston.

v = volume of compression space.

The "Air Standard" gives a very high value, so Dugald Clerk in "The Gas Engine" gives the "maximum available efficiency" as 0.8 of the air standard.

Fig. 5 shows the relative values of the "air standard" and the "maximum available" efficiencies as a percentage of the total heat energy of the fuel consumed.

An Efficiency Curve

Returning to Fig. 4, a curve of available efficiency is there shown. This curve is the brake thermal efficiency taken as a percentage of the maximum available efficiency as given in Fig. 5. This curve shows the engine performance in rather a better light, and gives a better idea of the engine efficiency.

The remaining items to be considered are shown in Fig. 6. These are b.h.p. per liter of swept volume, and engine weight in lb. per b.h.p. The curve of b.h.p. per liter is a function of the b.h.p., and is constructed by dividing the b.h.p. by the total swept volume of the engine in liters for various speeds throughout the range of the engine. Similarly, the weight per b.h.p. is constructed by dividing the weight of the engine by the b.h.p. developed. Both these curves are useful as a basis of comparison between engines.

Mention might also be made of oil consumption and compression pressure. Oil consumption is not so readily measured, as it requires rather a long period really to determine this factor, so that in general it is given a constant value, and averages approximately one-tenth of the fuel consumption, viz., .05 to .08 pint per b.h.p.-hour. In vehicle work the oil consumption is generally given as so many miles per gallon.

Compression pressure can be taken by gage while the engine is running, and the curve constructed from the values. This curve will give the maximum compression pressure at the various speeds. It is more general, however, to quote the compression ratio, that is $\frac{V+v}{v}$, as previously referred to. This ratio varies over a range of from 4 to nearly 6. The engines of racing cars approach the higher value. A compression ratio of 4 will give a pressure of 70 lb. per sq. in., and a ratio of 5 about 100 lb. per sq. in. Compression falls off at high speeds, due largely to wire drawing and heating of the inlet gases. The best value for good volumetric efficiency seems to be somewhere about 120 ft. to 130 ft. per second past the valve for inlet.

Having now completed the list of data required for an engine test record, the information to be gleaned from the various curves will be briefly considered.

The curve of b.h.p., Fig. 1, generally takes the form as shown, but in some cases the straight part continues to high speeds, whereas in others the curve falls away rapidly after about 1200 revolutions. The differences are due to small or tortuous gas passages retarding the flow of the gases, so that the cylinders are not being so well filled, and to the relatively larger proportion of heat lost to cooling and radiation at the lower engine speeds. The reciprocating weight also affects the power and speed. These differences are clearly shown in Fig. 7, where are plotted comparative curves taken from a heavy vehicle engine, a good car engine, and a racing type of engine, all of approximately the same cubic capacity. In the racing engine, the gas passages are liberal, consistent with the speed at which the engine is designed to run, and the moving weights are reduced to a minimum.

Torque and M. E. P.

Mean effective pressure and torque, Fig. 3, can be treated together, being similar functions of the b.h.p. The curves as shown are characteristic of average engines, varying in value and the amount of falling off at low and high speeds. As with b.h.p., the falling away at low speed can be accounted for by the larger proportion of heat passing to the cooling water; also to poor mixture with regard to quality and quantity. At the highest speeds the proportion of heat lost to cooling is relatively smaller, but the volume of gas entering the cylinder is reduced, as previously explained, hence the falling off. By way of example, suppose there are two engines of the same cubic capacity, one with twelve cylinders and the other with four. The torque curve for the twelve-cylinder engine would, in all probability, show a lower value at low speeds, due to the heat lost to cooling by the relatively greater cylinder surface for the volume. This lower torque would, of course, mean less h.p. at these speeds. The torque curve also gives the critical speed of the engine—that is, the point at which maximum power is developed relative to the engine r.p.m.

The curves of efficiency, Fig. 4, tell a similar story, and, in addition, the brake thermal efficiency curve gives the best engine speed for maximum thermal efficiency. In the case under consideration the best efficiency is at 1600 revolutions. In other words, the most economical speed with regard to petrol consumption is at this speed, as shown in Fig. 2.

Mechanical Efficiency

Friction hp., Fig. 1, and mechanical efficiency, Fig. 4, can be treated together, as the one is directly related to the other. The mechanical efficiency shows the influence of reciprocating weights and engine friction at a glance, and makes a strong plea for the reduction of these factors. An average value for mechanical efficiency may be taken roundly at 80 per cent, although in some cases 90 per cent has been reached.

The curves of b.hp. per liter and engine weight per b.hp., Fig. 6, give comparative values between engines for these factors. Average values of b.hp. per liter at normal engine revolutions may be taken at 8 for commercial vehicle engines, 12 for touring car engines, 10 to 15 for aeroplane engines (according to the engine being of the direct drive or two-to-one reduction design), and as high as 30 for racing engines. The engine weight per hp. may be taken approximately at 20 lb. for commercial vehicles, 15 for touring car engines, 5 for aero engines, and somewhere about 8 for racing engines.

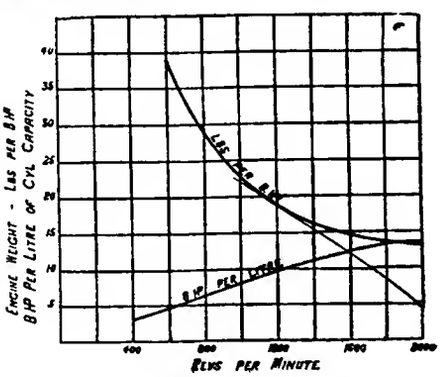

Fig. 6

With reference to the hp. curve, mention might be made that the position of the sparking plug has considerable effect on the power developed. Fig. 8 shows such a test result taken from an old type T-headed poppet valve engine. The sparking plug was normally situated over the inlet valve, when the power developed was as shown by the lower curve. By putting the sparking plug in the center of the combustion chamber the very substantial increase of power, as shown by the upper curve, was the result.

Present-day engines of the sleeve valve type and the overhead valve type naturally embody this feature in the design, and this probably accounts to some extent for the comparatively better power results given by such engines. Two sparking plugs per cylinder seem to have a similar effect.

Not Highly Accurate

In conclusion, the author would like it to be understood that the foregoing notes are not to be taken in the light of scientific experiment or investigation demanding a very high degree of accuracy in all results, and which, incidentally, would absorb much time. The aim is to make known the uses of such data as can be obtained in the routine work of engine testing, such as is done in the usual course of manufacture.

With Special Engines

Extraordinary results can be obtained with specially made engines, and it is up to manufacturers to incorporate these improvements as far as is practicable. But there are often parts in those special engines that are almost impossible from a commercial manufacturing point of view, or of so drastic a nature that the change would mean a big effort financially, and probably running the gauntlet with regard to popularity.

Test records made in the course of manufacturing have a most significant value, and may be of even greater value at the moment than what might be termed highly scientific research, because of the fact that these are the records of a commercial product. The higher researches get their reward in course of time, as improvements in design and efficiency become part of the manufactured article, and are as a guiding star to the industry.

General Charts of Value

In addition to the records of individual engines, general charts for each item and type of engine should be constructed. These general charts would all be plotted at the normal engine speed, or for similar engines at some predetermined speed, and would show at once the value of new experimental design and the general progress made.

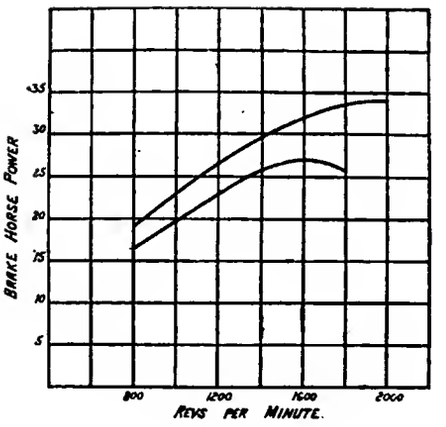

Fig. 8

Tanks—A British Account

IN its issue dated Sept. 22 *The Auto*, England, prints the following editorial, which is interesting, as it gives some of the history relating to the creation of the tanks, or super-armored cars, though it gives us no more than we have already had regarding the size or detail of these impressive machines. The British automobile press is, as a whole, so very reticent in mentioning the tanks that it is obvious no information is going to be available for some time to come. There seems, however, no doubt but that they are about the largest caterpillars ever built, and that they embody many ideas from both sides of the Atlantic. The editorial in *The Auto* says:

"At last the armored car appears to have really come into its own. No one who read Sir Douglas Haig's dispatch and the graphic accounts sent by the correspondents at the front relating to the work of the 'tanks' during the last great advance could have any doubt as to that. It would be going too far to say at this juncture that armored cars are destined to exercise a decisive effect on the fortunes of the war, but that they are likely to prove of superlative value there can be no room for doubt.

A New Weapon

"It is impossible for us at the moment to trace the full history of British armored cars in the present war. Not the least interesting of the post-war stories, however, will be that of the inside history of this new arm of the service—and written it will be when the time comes.

"The outbreak of the war found us without anything in the shape of a fighting car. In that we were not singular. As a matter of fact, we believe that the Germans were the only power possessing such vehicles. True, there were fighting cars of a kind, but these were anti-aircraft cars pure and simple, and thus did not fall within the category of armored cars as we now understand them. Even of these we ourselves possessed none.

"It was the navy which was responsible for their introduction to our own service. In the very early days of the war naval aeroplane squadrons were sent over to operate from Dunkirk and Ostend, and with them went certain improvised armored cars, which were constituted into a small force known as 'Aeroplane Support.' Considering their limitations of construction and armament, these cars did remarkably well, but it was seen that the type was quite unsuitable for the purposes of the fighting as it developed after the first 2 months of war. Then was evolved the real armored car as we knew it when it was working under the R.N.A.S., completely armored, with a revolving turret and armed with one or more machine guns. The navy was fortunate at that time in having at its head a first lord with imagination. It is not too much to say that had Mr. Churchill not been at the Admiralty when he was, there is a strong probability that armored cars and 'tanks' would not have come into being until long after they did. Clearly, armored cars are a part of the land service and, *per se*, had nothing to do with the navy. Still it was left to the navy to develop the arm, and Commodore Sueter, who was then at the head of the air department, threw himself into the job with the same enthusiasm with which he had pioneered the submarine and the aeroplane. The result was the R.N. Armored Car Division, which under Commodore Boothby and his officers became a highly disciplined and efficient force. Its units served and did well wherever there was fighting to be done. In France, Gallipoli, Egypt, Southwest Africa and East Africa, and even now in Russia, the naval cars and their personnel have rendered good service.

Evolving the Tanks

"All this time experimental work on a new and better type of heavy vehicle, more suitable for trench warfare, was being carried on, and when, from motives of policy, the army took over the cars from the R.N.A.S. rather more than a year ago, these experiments had practically resulted in evolving the design of the vehicle which has just proved such a surprise to the Germans."

Collier Is Rugged Light Truck

A Real Truck Design for Light Loads—Runs on Pneumatic Tires

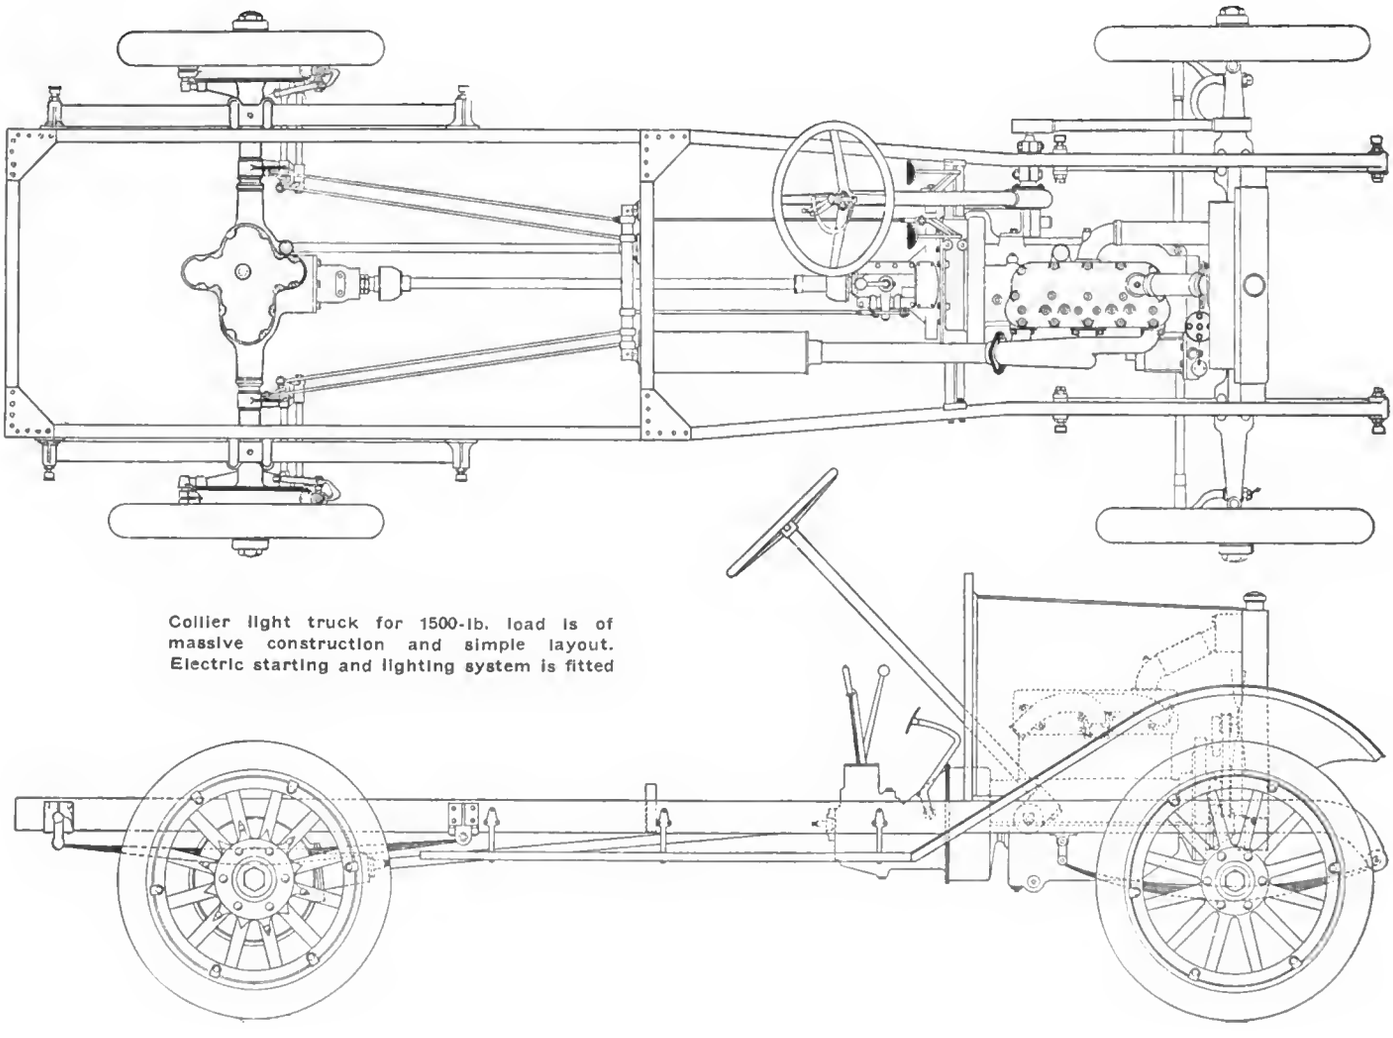
THERE are not very many 1500-lb. trucks that are really built for the job and are something more than extra strong passenger cars. One of the select few is the Collier, built by the Collier Motor Truck Co., Painsville, Ohio. This has a special Lycoming engine with four cylinders 3¼ by 5 in. with detachable head, making for easy carbon removal. The crankshaft has two bearings and is 2¼ in. in diameter; the valves are 1⅛ in. with ¼-in. lift and are operated by mushroom type cam followers. A somewhat unusual feature for a truck is the provision for an electrical starting and lighting system, this being a two-unit Dyneto outfit. The flywheel is recessed, and has a steel ring gear attached to is so as to guard against any risk of the teeth chipping. Lubrication is cared for by a gear pump and cooling is thermo-syphon, there being a 16-in. fan mounted on annular ball bearings. Either a Carter or a Zenith carbureter is fitted.

The clutch is a dry disk and the gearset gives three speeds, the transmission being in unit with the engine. All bearings, including the spigot bearing in the flywheel, are annular type ball, and the shafts are nickel steel. The rear axle ratio is 6 to 1, this being the high gear, and the low and intermediate gears give 18 and 10 to 1 respectively. The reverse is extra low for maximum leverage, being 24 to 1.

For the final drive a straight bevel is employed, this being easily accommodated of robust proportions with so high a ratio as 6 to 1. The axle is three-quarter floating, and a special point is made of mounting the spring tables very close to the wheels, so as to eliminate bending stresses on the ends of the axle sleeves as much as possible. Both brakes are on the rear axle, the foot brake being the external member of the pair. There are two universals designed to hold a large amount of oil and to require only occasional attention.

For the frame channel steel of a heavy section, 4 by 1½ by ¼ in. is used; very heavy spring hangers are used and these are held in place with an extra large number of rivets. On the springs the main leaves are made from silico-manganese steel to guard against breakage near the eyes, the other plates being heat treated carbon steel of the best grade.

Despite its robust construction the total weight is not excessive, so the tires used are 33 by 4 in pneumatic, on demountable rims. Crowned fenders are supplied of 20 gage steel, and there are running boards of heavy ash. Ash is also used for the body which is finished in vermillion and is 6 ft., 6 in. long, measuring from the back of the driver's seat to the tailboard.



Collier light truck for 1500-lb. load is of massive construction and simple layout. Electric starting and lighting system is fitted

The Rostrum

Overheating Causes Knock on Hills

EDITOR THE AUTOMOBILE:—I have a Buick C-25 driven about 10,000 miles which develops a knock on the hills and lack of power. Retarding the spark relieves the condition for several hundred feet when the knock is again apparent and engine has no power. Shifting into intermediate does not overcome the knock until the engine is running about the maximum speed on this gear. This trouble arises on grades that a 25-hp. engine should make with ease on direct drive. The knock is not so noticeable after having carbon burnt out but after running less than 100 miles it is as bad as ever. I have changed the firing point to at least six different positions, both retarding and advancing, but always return to the one setting which I find operates best. I have equipped the car with a Schebler carbureter and have tried various mixtures but, as with the spark, I find one setting is more satisfactory than others, neither spark nor mixture experiments relieving the trouble in question.

It has been suggested that I place shims under the cylinders, raising them anywhere from a 30 sec. to 1/16 of an inch, but as this would increase the combustion chamber I believe such action would make conditions worse. Being familiar with gas engine principles, what would your opinion be on this?

In view of the fact that all other units are apparently in perfect condition, also that compression is good, fat spark at each plug, connecting-rod and main bearings all tight, I would appreciate your views as to what causes this and also what action would be necessary to overcome the trouble.

The knock is a typical carbon clink, but the burning out of all carbon only partially overcomes the defect and it is only a question of 50 or 100 miles and the trouble is as bad as ever.

Norwood, Ohio. C. K.

—It appears that your trouble is probably due to overheating. Two possible things might cause this, one that the pump is not operating properly. Sometimes the pin holding the impellor of the pump shaft shears off and then the water circulation will be greatly restricted. This will heat up the water in the engine but it will not necessarily cause steam to be produced.

Another thing which sometimes happens is that the rubber hose connections give way internally and almost close up the hole with a spongy mass of rubber and cotton. It cannot be that the compression is wrong since these cars were designed to have quite a normal compression.

Knock Probably in Oldham Coupling

Editor THE AUTOMOBILE:—I have a Buick M 10 which has a peculiar knocking in the transmission. In letting the car run slowly on smooth road it sounds like a crooked shaft wabbling. In running fast on smooth roads it is a knock, in climbing hills it is a sort of pounding, on low gear or reverse this is not heard at all. I have put a new front transmission bearing and tightened the back one but this makes no difference. When the car is standing and the motor not running, by taking hold of high speed lever and sliding forward gently the transmission as far back as reverse seems to slide ahead about ¼ in. but reverse does not move. I also notice that the transmission shaft works back and forth and has worn a notch into the front bearing hanger about ⅛-in. deep. I took the bearing out and turned the hanger around and it has worn the other side of the hanger the same way. This has been bothering me for some time.

I have been to two of the best garages around and one says the large brass bushing in transmission is worn; the other says that the high speed yoke is out of adjustment. Can you tell me what it is?

Ceres, N. Y. H. A. L.

—From your brief description we believe the noise is caused by the knock of the Oldham coupling at the front end of the transmission, inasmuch as the car has been driven probably at least 5 years and the coupling is badly worn.

With reference to the transmission sliding forward ¼-in. this is no doubt caused by the thrust washers being badly worn and in need of replacement. This could be greatly improved by taking up on the adjusting screw located on the rear end of the transmission driveshaft. We would suggest that the transmission be given general overhauling as the end play is probably the direct cause of the excessive wear on the front bearing hanger.

Ford Accepts Only Unemployed

Editor THE AUTOMOBILE:—Could you tell me how the Ford Motor Co. employs help? What wages and what hours and if one is obliged to be a citizen of Detroit any certain length of time?

Edmeton, N. Y. L. C. H.

—The Ford Motor Co. employs only people who are out of work, who have been residents of Detroit from 3 to 6 months and who make application in writing to H. Sommers, superintendent of employment. Wages after a probationary 6 months are $5 a day as a minimum basis. Working days are 8 hr.

Climatic Conditions Affect Carbureter

Editor THE AUTOMOBILE:—Is there a Singer agency in Boston, and if so, what is its address?

2—How is Moto-Meter pronounced?

3—Are gearless differentials good? Why is it that automobile manufacturers do not use them?

4—Are not carbureters affected by climatic conditions? How are they adjusted?

5—I have a Chalmers which needs repainting and has a few bumps in the fenders? The tire average is about 1800 miles. The engine could have more compression and the battery is a year old. Otherwise it is in good mechanical order as far as I know. About how much could we expect if we turned this car in?

Cambridge, Mass. A. McM.

—There is no Singer agency in Boston.

2—As two words. Notice the spelling which is the style adopted by the company.

3—Many manufacturers next year will be using differentials other than the ordinary kind.

4—Heat, cold and variations in humidity will affect the

carbureter. The necessary adjustments to changes in climate depend entirely upon the design of the particular instrument.

5—Used cars are not at present selling for very good prices. It would not be possible to give you an estimate as to the value of your car. Even after an expert examination it would be almost impossible to say if your car was worth exactly so much.

Cannot Take Hills on High

Editor THE AUTOMOBILE:—I have a Warren-Detroit which has a 4⅛ by 4½-in. bore and stroke. The timing was scaled on rod through head. Exhaust valve opens 1 7/16 before bottom center and above 3/16 in. past top center. Intake starts to open as exhaust closes and is fully open when exhaust valve is seated. Intake is closed 1/16 past bottom center. Is this correct? Car will easily make 50 to 55 m.p.h. on level, has good compression, good spark, but will not take the hills on high as it should. The car rolls very easily by turning the propeller shaft with my hands. Can you suggest anything that will liven it up?

Bondsville, Mass. F. L. W.

—Your car cannot be expected to take hills on high in the way that a modern machine will do. Possibly the reason is that you have an extra high gear ratio in the rear axle which would make the speed, but would not permit good high gear performance on hills.

It is unlikely that the timing is wrong since the particulars you give would suit good pulling at low speed better than they would suit high speed. You might try the effect of changing one tooth and make the inlet valve close that much later.

Definition of a High-Speed Engine

Editor THE AUTOMOBILE:—What speed does a motor have to make to be classed as a high-speed motor?

2—What is the maximum speed of the Ford motor and the block r.p.m.?

3—What is the meaning of backfire?

4—What is the fastest mile to date made by a motorcycle, what machine and who holds the record?

Harpersville, N. Y. C. W. B.

—A piston speed much in excess of 1000 ft. per minute causes an engine to be rated as a high-speed one.

2—The Ford engine has a normal speed of about 1000 r.p.m. which is what you probably mean by the block revolutions. If allowed to race it might reach 3000 r.p.m. for a short time.

3—When the explosion takes place too early while the piston is coming up on the compression stroke it will reverse the direction of rotation, blowing the piston back again. This is called the backfire. The same word is often used to describe explosions in the muffler caused by an unfired charge being passed through the valve and down the exhaust line where it is fired by the next exhaust. This is not really a backfire.

4—The fastest mile in a motorcycle was made by Humiston in an Excelsior at Los Angeles, Cal., in 36 sec.

Speeding Up a 1908 Ford

Editor THE AUTOMOBILE:—I have a 1908 or 1909 Ford which has circulating pump that I would like to build over into a speedster. Would like your advice regarding changes to be made to give best results. Would rather increase the speed of the motor than make the gear ratio more than 3 to 1.

Genoa, Ohio. G. L. B.

—You would probably get the most satisfactory results by changing the gear ratio. There are several firms who make special gears which will fit the Ford axle and you could get what you want from one or another of them. To get speed from the engine you should see that the crankshaft and connecting-rod bearings are particularly well fitted, that the valves have not been so much ground that they are beginning to sink into the cylinders and of course that the ignition and carbureter are working as they should. It is sometimes possible to gain speed by shortening the intake manifold and raising the carbureter although you will have to rearrange the fuel feed to allow you to do this. You can also obtain sets of aluminum alloy pistons ready to fit to a Ford engine and these will give you many more revolutions without overstraining the crankshaft.

Wiring Diagram of Maxwell 25

Editor THE AUTOMOBILE:—Kindly publish diagram of electric lighting, starting and ignition system of Maxwell 25.

Hamburg, Pa. C. E. K.

—Diagram of the Maxwell electrical system appears in Fig. 1.

1000-Lb. Denmo Has Electric System

Deliveries on New Model To Start Dec. 15—Production Plans Laid for 5000 —Price To Be Under $800

BESIDES its 1¼-ton truck brought out a month or more ago the Denneen Motor Co. is bringing out a 1000-lb. wagon on which deliveries will start Dec. 15. It is planned to build this light vehicle in quantities of 5000 for the coming fiscal year and to sell it somewhere between $750 and $800.

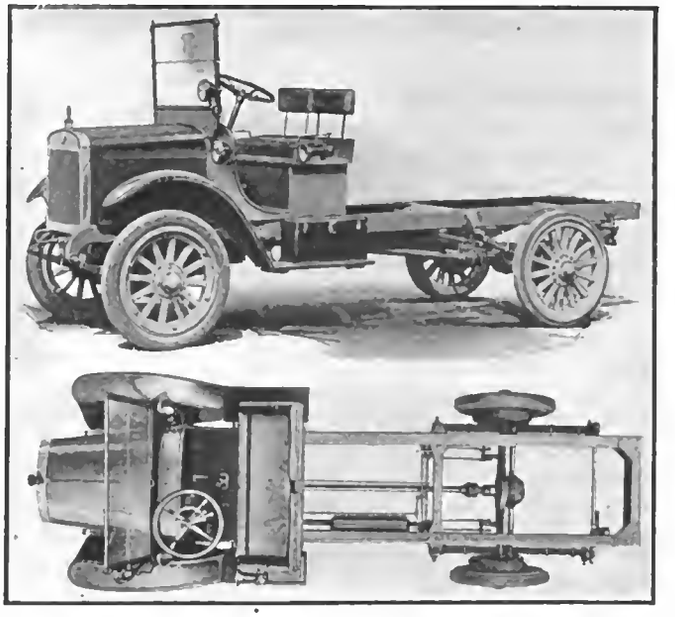
Like the larger vehicle, this 1000-pounder will be regularly equipped with an electric starting and lighting system, windshield, Boyce Motor-Meter. The standard Splitdorf generator and starter motor are used, the generator being so set as to cut in at approximately 5½ m.p.h. and to reach its maximum charging rate of 12 to 14 amp. at 11 m.p.h. This is the same as on the larger model. F. S. Denneen, president and designer, says that in the 1¼-ton capacity experimental truck the battery did not require recharging in a year of testing and general use. He calculates that in ordinary use the engine will run considerably more than the vehicle and so the possibilities of sufficient recharging are quite sufficient for battery needs.

In adding a complete electric lighting and starting system for light-capacity vehicles of this kind Engineer Denneen believes it possible to secure a better type of driver and also to economize quite materially in fuel consumption per year. The Gould battery is protected against jar by a spring mounting of the crate, which has worked out very successfully.

The use of pneumatic tires on the front wheels of the larger truck and on all four wheels of the 1000-lb. vehicle is in keeping with Denneen's plans to conserve the motor as much as possible and also make the truck easier to operate. When you start with electric starting and lighting, and add to this pneumatic tires and windshield you are giving the truck driver most factors necessary to conserve his energies, and if the conserving of driver's energies results in greater care for the truck and its machinery, then all of these parts should work for greater economy in the long run.

Both Denmo models are assembled jobs, the work of assembly being carried on in the Denneen Cleveland factory where 125,000 sq. ft. of floorspace is available and where the present capacity is ten trucks per week.

The units used in the 1½-tonner include Wisconsin 3¾ by 5-in. four-cylinder motor, Grant-Lees three-speed gearset, Torbensen front and rear axles, Ersac propeller shaft and universals, Fedders radiator mounted on a special spring-supported frame cross member, Pierce engine governor which governs according to the speed of the vehicle and not by the speed of the engine, Cooper springs, Borg & Beck dry-plate clutch, and 34 by 4½-in. pneumatics in front and 34 by 4-in. solids in rear. To these are added the Splitdorf electric starting and lighting outfits and Dixie magneto for ignition. The vehicle sells for $1,385.



Chassis of Denmo 1¼-ton, showing internal gear rear axle

Unit power plant construction is employed, the Wisconsin engine being incorporated with the clutch and gearbox.

Thermo-syphon water circulation cools the engine, the radiator being of the Fedders cellular type, incased in sheet metal and mounted on a steel cradle, spring-mounted. This cradle extends across the bottom of the radiator so that there is no tendency for it to sag, the springs being flat ones, looped forward.

Gravity gasoline feed supplies the Stewart carbureter, and a short connection from a stove on the exhaust header furnishes hot air. The carbureter is mounted high enough to secure a short passage to the valves. The Pierce governor, driven by flexible shaft from behind the gearbox instead of from the motor, this drive limiting the truck speed only and having no effect on the motor otherwise. Thus the full power of the motor is available on the lower gears.

In the lubrication system of this motor pure pressure lubrication is used, a gear pump forcing the oil from the reservoir to the helical timing gears and over the bearings.

Driving the three-speed selective gearset is a Borg & Beck dry-plate clutch, from which the drive is taken on an approximately straight line, thanks to the tilting of the motor, to the Torbensen internal-gear-driven rear axle. Brakes on this axle are external and internal, the latter being foot-operated and the latter actuated by the hand lever.

The Hotchkiss drive principle is followed, the master leaves of the rear springs being made of vanadium steel for this purpose, the other leaves being of carbon steel, heat-treated. The radiator is carried well forward of the axle to shorten the wheelbase and still allow a generous length of load platform.

ACCESSORIES

Lexington Safety Signal

TWO circular 8-in. casings containing indicator dials and the necessary mechanism are the salient points in this signal. One of these casings is mounted at the front and one at the rear of the car, the front one having a small window for the observation of the driver, showing the working of the indicator and lamps. A black arrow on the white background of the casing points the direction the driver intends to take, and at night or in bad weather the arrow signal works in connection with the lights. There is a stop signal in the rear attached to the casing, consisting of a white hand with the word "Stop" in white letters. When working it is thrown into a horizontal position, with a red light directly over the word "Stop."

A 3½-in. three-way switch in a brass casing is clamped to the steering column under the wheel and operates the signals by four pushbuttons. The top button works the arrows to the right or left, and also the lights when the current is on. Another pushbutton on the top throws the current for the lights off and on, while the pushbutton underneath works the "Stop" signal. Another button on the end works the horn. The main feed wire is run to each indicator and to the switch on the steering column and then to the battery, return wires being properly connected. All wiring is run through conduits, preventing interference in any way with other parts of the car.—Lexington Signal Co., Lexington, Ky.

Tar Remover

Asphalt or tar if allowed to remain on the car will discolor the varnish and destroy the finish. The directions for use of this tar and oil remover are as follows: After washing the car with soap and water and removing all grit, saturate a piece of cotton waste with the liquid and apply it to the damaged surface. Allow it to stand for a few minutes, and then rub thoroughly with the same piece of waste. Price, per pint, 50 cents; per quart, $1.—Cooper & Osterhout, Watertown, N. Y.

Union Piston Ring

Union rings are especially adapted to the small-bore, long-stroke engine in which good compression is essential to the high speeds necessary. The illustration shows the method of preventing leakage at the joint, the broad surface of the ring coming into direct contact with the cylinder walls and the blades fitting into the piston grooves being protected from breakage, the idea being to provide a perfect metal packing. Union rings are made from individual gray-iron castings, and the scale of the casting is retained in the ring to give maximum resiliency. The rings are ground to exact measurements after the union is inserted to insure a perfect fit. Rings of 2½-in. diameter and under sell for $1; 2½ to 3½, for $1.25; 3½ to 4½, for $1.50; 4½ to 5½, for $1.75, and 5½ to 6½ in. for $2.—Union Products Co., Rockford, Ill.

Union piston ring, showing the union

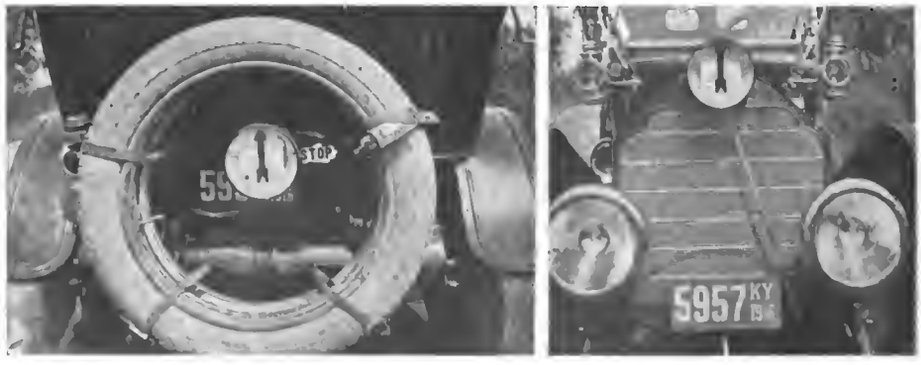
Lyon self-lubricating spring details

Rex Tire Pump

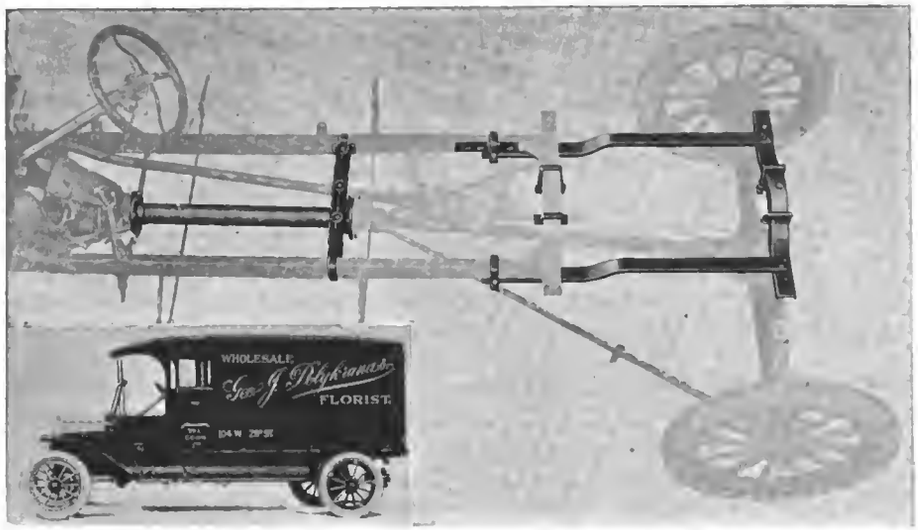
As there are no valves in this single-cylinder pump it may be operated at high speed without impairing its efficiency. The action of the pump shaft gives the piston both a vertical and laterally oscillating movement; in the side of the piston a groove is so located that when the piston starts upward on the compression stroke this groove coincides with the delivery port in the cylinder and remains in that position until the end of the stroke. The piston then oscillates, covering the outlet port and preventing the return of the air. At the end of the downward stroke the piston uncovers the vacuum passages, allowing air to rush into the cylinder. While the piston is traveling down and back over the intake port it is rotating in the cylinder, so that the delivery port is uncovered shortly after the intake port is closed.—Rex Pump Co., Chicago, Ill.

Lyon Self-Lubricating Spring

These springs are designed to use light cylinder oil, sufficient oil for about 3000 miles travel being retained by a felt pad carried in a concavity near the end of each leaf. Oil is reapplied with an ordinary oil can through a small duct from the end of the leaf. In the normal position of the spring there is only a slight pressure on the oil pad, but when running this pressure is varied by the road inequalities so that the pad acts in the manner of a sponge. Very little oil is forced to the outer surface of the pad and this is taken up by the spring leaves



Lexington safety signal, showing the two casings with indicator dial, one attached to the rear and one to the front of the car. Note stop signal



H-D extension for Ford cars, permitting the lengthening of the wheelbase 15 or 30 in. as on car illustrated at left

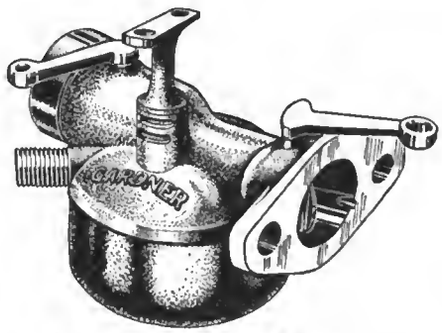
throughout their length by capillary attraction, insuring positive lubrication. The manufacturer carries in stock over 400 different numbers of springs.—Edward F. Lyon Co., Detroit, Mich.

Gardner Thermostat Carbureter

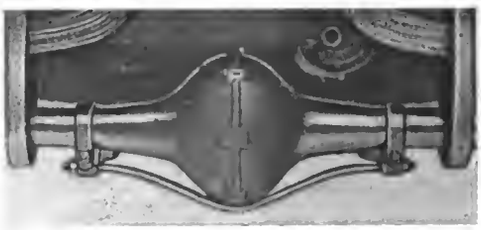
With this carbureter, designed for Fords, the gasoline supply is automatically controlled by means of a metallic thermostat. This thermostat is an integral part of the carbureter and requires no adjustment. It consists of a metal plug at the carbureter termination of the supply line and contains two openings admitting the fuel to the mixing chamber. One of these openings is controlled by the thermostatic flap-valve actuated by the changing temperature. In starting when the motor is cold the valve is open, giving a rich mixture. As the motor warms up the valve closes, giving an economical running mixture. The device sells for $10.—Gardner Carbureter Agency, 680 Woodward Avenue, Detroit, Mich.

H-D Extension for Fords

Simplicity is a feature of this extension, only five parts besides the brake-rod lengthening equipment being required to lengthen a Ford chassis 30 in. There is also a 15-in. extension, but the manufacturers consider the 30-in. type more generally desired. When the chassis has been lengthened it may be fitted with either a delivery or truck body or a seven-passenger touring design. The extension consists of a propeller shaft, tubular propeller shaft housing, a frame extension and the necessary equipment for lengthening the brake rods. The makers state that anyone can attach the device with a wrench and a hammer in a few hours, no boring or machine work being necessary. The extension may be removed at any time and the chassis restored to its original dimensions. Its use is especially advantageous, it is claimed, for fitting a Ford for the delivery of the small parcels which make up the great bulk of retail business. The 30-in. size sells for $60, complete, and the 15-in. size for $55.—Hayes-Diefenderfer Co., 237 West Fifty-fifth Street, New York City.



Gardner Thermostatic carbureter for Fords



Hoyt's axle truss for Fords

Weaver Towing Pole

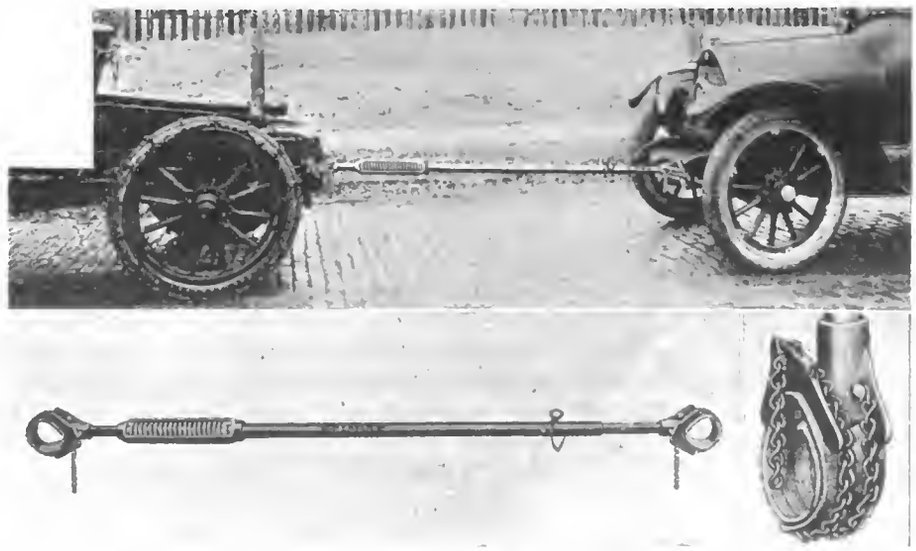
An adjustable-length pole that may be fastened to the front or rear axle of any car, enabling it to be towed with safety. The pole proper is made from steel tubing which is adjustable from 5 ft. 6 in. to 8 ft. by means of a keypin. At each end are metal sockets carrying a 30-in. leather strap that permits attachment either to the axle, spring or frame. The towed car may be pushed backward, cannot jam into the forward car on hills, and all shocks are absorbed by the double-acting spring mounted in the pole. Price, $10.—Weaver Mfg. Co., Springfield, Ill.

Hoyt Axle Truss

With this device the Ford rear axle is strengthened by a steel rod passing under the differential housing and clamped at each end to the rear axle. The device is claimed to take much of the strain from the central retaining bolts and to promote the life of the rear end assembly. It is easily installed and may be bolted in place by the owner. Price, $1.50.—Hoyt's Auto Supply Co., 370 Fairfield Ave., Bridgeport, Conn.

Rub-R-Tite Patch

This is a water-tight patching for tops, side curtains and cushions. After cutting to the desired size, the linen coating is removed from the adhesive side and the patch applied. It is said that the patch is scarcely noticeable. Price, one sheet, 4 by 12 in., 50 cents.—Auto Products Co., 40 Elm Street, Buffalo, N. Y.



Weaver adjustable-length towing pole, its application being illustrated above. Detail of socket is shown at the lower right

Solving the Glare Problem

AT the January meeting of the S. A. E. the electrical equipment division of the standards committee offered the following resolution:

"Whenever there is not sufficient light within the limits of the highway location clearly to reveal all persons, vehicles, or substantial objects within said limits for a distance of at least 150 ft. the headlights of any motor vehicle in motion shall give sufficient light to reveal any person, vehicle or substantial object on the road straight ahead of such motor vehicle for a distance of at least 150 ft.

"The headlight shall be so arranged that no portion of the reflected beam of light, when measured 75 ft. or more ahead of the lamps, shall rise above 42 in. above the level surface on which the vehicle stands. Such headlights shall also give sufficient side illumination to indicate any person, vehicle or substantial object 10 ft. from the side of such vehicle at a point 10 ft. ahead of the lamps.

"The term 'beam of light' as used in the above provision shall be construed as meaning the approximately parallel focalized rays gathered and projected by a reflector, lens or other device."

When the report came to be threshed out in the general meeting the recommendation was cut down to merely the portion printed above in italics; it being considered by the majority that the original resolution was too sweeping; that it savoured too much of legislation and too little of pure engineering.

As amended the resolution was insufficient, as it stood originally it provided a definition for adequate light without excessive dazzle or glare. The great thing was that it defined what the light *should* be as well as what it should not be.

Glare Merely Contrast

Glare is simply contrast; it is the contrast between the bright patch of light and the dark surroundings. The human eye can bear a certain degree of contrast but no more; the S. A. E. definition goes practically far enough in its original form to define a degree of light and a system of lighting that will prevent too great a contrast from being presented to the ordinary user of the road. It is not a matter of volume of light at all, for there are many small side lamps giving a totally inadequate light for driving which are none the less able to glare horribly.

Unassisted, legislation might take the mistaken course of limiting the amount of light, which would not, of itself, help the glare question, while it would tend to make night driving unsafe by reason of robbing the driver of his power of sight. Too little light is as dangerous as glare to the road user, who may be overlooked altogether if he is not illuminated adequately.

The S. A. E. after modifying the original resolution and so greatly curtailing its value, asked that research work be done so that the resolution could be enlarged, stating in exact terms of scientific accuracy the degree of illumination desirable or necessary. This research work is being done and has been largely accomplished. The society will very soon be able to frame an entirely scientific recommendation which will not only state the amount of light necessary and the way it should be directed, but will tell how that amount of light and how that direction may be obtained.

Body Fashions

IN two years we have seen the average automobile body change from what now seems a rather clumsy assembly of curves and straight lines into a "continuous line" shape. Our automobile bodies today are not really streamline, for to be so they would need to have the largest section in front instead of behind, but all body designers seem to be aiming at the torpedo as the ideal shape.

How long will this craze last? Is it a permanent thing or is it to be succeeded by something altogether different?

In America the extremes of the European body builders have not yet been reached; the streamline type as it is called, can be developed much further than it has been carried. Say that we have a year more, or perhaps two, in which streamline bodies can be built to new designs and actually look different, and the question of what will follow arises.

In one or two instances it is possible to observe a breaking away from the curved plan view outline combined with parallel side elevation. Some of the most lately introduced cars have sharp lines in them, some have actual angles.

Argentine Trademark Law

Register Trademarks Before Cars Are Shipped—Dealer's Protection Needed

BUENOS AIRES, ARGENTINA, Sept. 15—U. S. A. automobile and accessory manufacturers should give early attention to the proper registering of trademarks in Argentina, otherwise they may find themselves barred from the privilege of using their own trade name.

There are certain U. S. A. cars sold in Argentina under different names than in North America and Europe. Their trademarks were registered here by local concerns. There are other concerns that have had to pay fairly large sums of money, well up in the thousands of dollars, to some person who has registered their trademarks in this country and held the matter under cover until cars have reached the custom house in this city. Before the cars were taken out of customs the U. S. A. manufacturer had to make his peace with the party owning the registered trademark.

R. W. Huntington, one of the best known authorities on patent laws and trademarks, etc., in Argentina, has recently written for the *Review of the River Plate*, the leading financial review of this country, a comprehensive outline on the trademark law and practices in connection with it. Mr. Huntington is a member of the American colony here and is a leader in his profession.

There are several points in connection with Argentine patent law which differ so widely from U. S. A. customs that they should be carefully considered. For example, in Argentina a trademark may be held by the registrant even though he may not use it. He can have it as long as he desires before he commences to do business.

Trademark by Class

Then again, if you have a trademark for one class of goods it will give protection for all different classes of goods. If you register it for automobiles it will hold for goggles.

In connection with selling automobiles and accessories here, the Buenos Aires dealer must be protected. To do this the trademark under which your goods are sold should be registered in the name of the Buenos Aires dealer, which can be done with every safety, as outlined later.

The following are some extracts from Mr. Huntington's paper:

"It should be borne in mind that there is a radical difference in the very basis of the trademark law of this country and that of Great Britain and the United States, for example, in which *previous use* counts rather than previous registration, whereas in this country *these conditions are reversed.* This fact is the cause of much of the misunderstanding which has arisen among foreign manufacturers regarding the protection or lack of protection of such marks or names in this country and the conditions affecting such protection.

"In this country a merchant, manufacturer or agriculturalist may choose his distinctive emblem and secure it for himself by registration, even before he commences to do business, where in the United States, for instance, he must actually use the mark before he can register it. For this reason the Argentine law might seem more just to the man about to go into business and less so to the established merchant or manufacturer. It is extremely difficult for the human mind to disabuse itself of all self-interest in judging of the right or wrong of any given law or measure.

"But whatever our opinion may be on this point, we must take the law as it is and not as we may think it should be.

"Another difference between the law of this country and those of some others lies in the fact that here a trade mark or name may be held by the registrant even though he may not use it, or he may hold a mark for many classes of goods while using it for only one. This also, while it may and undoubtedly does seem unjust to the mind of a person accustomed to the opposite conditions, is not without its defense; for instance, why should I lose an emblem which I have invented because I am prevented by financial or other reasons from carrying out my intentions to use that mark for the time being? Or why should I, who have a certain mark which I use to designate some table delicacy, not be able to prevent someone else from using the same mark or a similar one for axle-grease or rat poison? If your trademark is original you should have the right to insist that no one else may use it for anything—that when that mark is mentioned the idea conveyed and received shall be the name of the article for which you have made it famous, and that exclusively.

Trademark Piracy

"It is true that this particular phase of the law and practice here lends itself to what has been called 'trademark piracy' on account of the strictly national interpretation which is given to the law, although there has been a marked improvement since the year 1912, previously to which it was the practice in the Argentine Patent Office to grant the registration of a mark for all classes of goods for a single registry fee. Since that time each one of the twenty-five classes into which the new Argentine classification then adopted divides merchandise for the effects of trademark registration must be

Freight Car Shortage Serious

Manufacturers Forced to Unusual Methods to Keep Shipments Close to Normal

DETROIT, MICH., Oct. 9—There is a shortage of 100 railroad cars per day in Detroit for automobile shipments. Using flat cars, Arm's palace horse cars, box cars and any other sort of a freight car with a 6-ft. door, manufacturers of automobiles in Detroit and other cities are attempting to meet with the serious shortage of freight cars suitable for transportation of automobiles, and they are finding it a difficult task.

Whether the blame for the shortage belongs to the 213,078 automobiles manufactured this year as compared with 139,829 of 1915, or to the vast grain movements now taking place, or to the delay in unloading of freight cars or, as many maintain, to the shortage in trackage and motive power, is not yet clear, but manufacturers are becoming pessimistic over the outcome and predict that even greater difficulties are sure to arise within the next few months.

Some Cut Production

Interviews with a number of car makers in Detroit disclose that many are now suffering to such an extent that they have been forced to cut down their production. At the Ford plant the traffic department reports that though they are not suffering much as yet, they have been forced to use ordinary box cars and to reload freight cars as soon as they are emptied in order to keep up to normal. Maxwell has been held up on shipments for the past 2 months and has seriously felt the shortage during the last 3 weeks. The company is using any kind of car with a 6-ft. door, and has had to cut down its production because of conditions.

At Packard private cars have been leased to care for the shipments, and up to the present they have been able to cope with the situation. Cadillac has suffered the greatest inconvenience through the Western equipment and, though running light on production at present, has had to use flat cars for the last 2 weeks. Studebaker has had several tie-ups and is shipping about three times as many cars at present as 3 years ago and is attempting to relieve the shortage by loading foreign cars to local points as far as possible. Hudson has leased many private Arm's palace horse cars, which are relieving them for the present, but shipping conditions are constantly becoming worse and take a pessimistic outlook. Many other companies report similar troubles.

Many plans are in process of consid-

eration and operation for the relief of the congestion. There are at present about 9000 railroad cars lying idle in the Detroit freight yards which are filled with household goods belonging to families in this city who have recently moved here and are unable to find apartments or homes in which to live. Every means is being used to have these cars unloaded as soon as possible. The Interstate Commerce Commission, local commercial organizations and the railroads are urging shippers to unload all cars as quickly as they can. The railroads have at the present time 10,000 new automobile freight cars in operation, as compared with a year ago, and have 8000 additional under construction orders, of which 5000 are expected to make their appearance this coming winter.

The railroads are attempting to prevent delay of unloading of cars by means of a higher rate of demurrage which they are trying to establish and which they believe will force shippers to unload. They claim that there should be a progressive charge, making it $1 per day per car for the first 3 days, $3 per car per day for the next 3 days and $5 per car per day for each succeeding day. It is likely that tariffs will soon be filed to cover this schedule.

—

Maibohm to Increase Production

RACINE, WIS., Oct. 5—The Maibohm Motors Co., this city, which began the Maibohm roadster about a year ago, is at present located in a factory of 110,000 ft. of floorspace and is making twelve cars per week.

The Maibohm company is an outgrowth of the Maibohm Wagon Co., which for 30 years has built vehicles. Experimental work on the first Maibohm car was commenced about 2 years ago.

—

Two Detroit Accessory Makers Bankrupt

DETROIT, MICH., Oct. 6.—Bankruptcy schedules, listing liabilities totaling more than $100,000 were filed yesterday in the United States District Court by the Victor Mfg. Co. and Ackerman and McNamara, two Detroit automobile accessory manufacturers.

The Victor Mfg. Co. is a Michigan corporation with its main plant in Detroit. It listed its total liabilities at $77,807 and assets comprising land and machinery at $114,724. The schedule was filed by Franklin T. Chapman, secretary and treasurer of the company. Adjudication was made Sept. 18.

Ackerman & McNamara whose plant is located at 535 Franklin Street, Detroit, listed their total liabilities at $39,606 and assets at $5,201. Adjudication was made August 29. Owners of the company are Joseph Ackerman and Frank McNamara.

Studebaker's Vast Expansion

Many Buildings Erected and Numerous Mechanical Changes Made in Year

DETROIT, MICH., Oct. 6.—This last year has been one of constant construction for the Studebaker Corp. Old buildings have been torn down and new ones added, factory methods have been overhauled and improved, and every feature designed to facilitate production has been adopted wherever possible.

A Year's Growth

Within the past 12 months three buildings have been erected, two structures enlarged and construction on another started. At plants numbers 3 and 4 where the additions are being made, a building 300 ft. long and 50 ft. wide, four stories high and constructed throughout of steel, glass and tile, has been equipped with a traveling crane which serves three floors and places stock directly from freight cars to the proper departments. The building will serve for frame assembling, storage and wheel painting.

The structure in course of erection will be 900 ft. by 50 ft., one story high and will be used for testing, tuning and getting cars ready for shipment.

Another new building consisting of one story 65 ft. by 140 ft. has been added to the heat treating and forging shop and will house work of similar natnre. On West Jefferson Street in the same plant, a one-story tuning and testing shop 50 ft. by 350 ft. has been erected and behind it a building has been increased from one to four stories and is used for a forge shop, wheel, rim and tire assembly and frame dip painting. There is also a new heavy forging shop 65 ft. by 265 ft. built entirely of steel, glass and tile.

New Forge Plant

The new building constructed for heavy forging is used for all crank shaft, front axle and connecting rod work. Three new 7000 lb. hammers, three 120-ton hydraulic presses for crank shafts and front axles, and four 2500 lb. hammers for connecting rods have recently been added to the general equipment. The shop is so arranged that all raw materials enter at the north end and are completed and inspected before leaving at the south end. The building is radical in its layout and differs from other plants, as the hammers and presses are ranged along the walls and the furnaces are placed in the center to secure ideal working conditions during the summer months. A 5-ton Toledo trolley crane serves the entire shop which is composed of a complete equipment of twenty-four forging furnaces and 4 Rockwell double chamber heat-testing furnaces.

One mile of new trackage has recently been laid and the Studebaker company can now load 100 freight cars on the company tracks at one time.

A new steel yard with capacity for 300,000 tons of forging steel and 400 ft. long by 65 ft. wide, has been added to the plant and takes the steel directly from freight cars by means of a 5-ton crane. The yard is so arranged that it feeds from the stock piled directly to the shears and to the two shops on each side of it.

Old Buildings Enlarged

The main building constructed 3 years ago has recently added seven forging gear blank headers and mnch minor machinery. It is 370 ft. by 65 ft. and until this year, was nsed to do all of the productive work at plants numbers 3 and 4.

An excellent illustration of the growth of the Studebaker Company is shown by the old De Luxe building. When the Studebaker Corp. purchased the site from De Lnxe there were several small buildings to the plant. To-day there is but one-half of a De Luxe building left and that is now used in connection with a new structure.

The Studebaker factory operates entirely npon a nnit system, and each separate piece is received in the raw in its specified room where it receives every part of the work needed to complete it and does not leave until it has been painted, inspected and made ready for assembly.

Conveyor System Used

Conveyors operate throughont the varions shops and carry the parts to the different assembly rooms eliminating all superfluons human movement.

Assembly work is carried on by a progressive plan. The third floor of the main building is filled with shops where parts are finished for assembly and placed in the conveyors to the fonrth floor. Here the frame starts at one end of the bnilding, receives its dip of paint and wheels with rims and tires inflated. It is then placed on a power conveyor and carried from room to room and point to point, receiving in each place, the varions additional parts it needs, until ready for the top, hood, floor boards and windshield which are placed on after the car leaves the power conveyor.

A one-story bnilding to cost $30,000, will be erected shortly at the South Bend plant. It will be used as a service station, stockroom, display room, and repair shop. Another story may possibly be added later.

Budd Wheel Co. to Enlarge

Will Have 3 Acres of Floorspace in New Body Plant of Budd Mfg. Co.

PHILADELPHIA, PA., Oct. 9—The Budd Wheel Corp., of Philadelphia, recently incorporated for $2,000,000 to manufacture steel and wire wheels of its own design, will occupy part of the new building being erected at Twenty-fifth Street and Hunting Park Avenue by the Budd Manufacturing Co., maker of all-steel bodies.

The new company will have about 3 acres of floorspace in the new building. W. B. Read is secretary and treasurer of both companies.

The new Philadelphia industry will be in charge of Charles Schenck, formerly with the Burdette Roundtree company, and well known in the railroad business. The stock is divided into $1,000,000 preferred and $1,000,000 common stock. Its officers are: Edw. G. Budd, president; H. L. Adams, of Chicago, and director of the Grant Motor Car Co., vice-president; W. B. Read, secretary and treasurer.

The Budd Mfg. Co. is at present turning out 1000 complete bodies a day and to meet the increasing demand for more is erecting the new building.

—

American 2-Tonner for 1917

NEW YORK CITY, Oct. 10—The American Motor Truck Co. has announced its 1917 model, a 2-tonner, equipped with a 36-hp. Wisconsin motor. The company's executive offices are in this city and the factory is in Hartford, Conn.

—

Elgin to Add to Factory

CHICAGO, ILL., Oct. 7—The Elgin Motor Car Corp., this city, which has increased its floor space more than 500 per cent within the past 80 days, will further increase it with an additional 200 per cent before another 60 days.

—

Herschell-Spillman Expands 25%

NORTH TONAWANDA, Oct. 9—The Herschell-Spillman Co., motor manufacturers, this city, is increasing its production 25 per cent by erecting a new building 165 by 65 ft., four stories in height.

—

New Stewart-Warner Buildings

BELOIT, WIS., Oct. 7—The large new foundry buildings being erected for the Stewart-Warner Speedometer Corp., Chicago, at the Warner works in Beloit, Wis., require a remarkable volume of materials. The specifications call for more than 1,000,000 brick; 120 tons of steel; 3000 cu. yd. of concrete, and 40,000 cu. yd. of filling ground, in addition to 50,000 panes of glass. The main building will be 122 by 522 ft. in size, and the auxiliary structure is 70 by 80 ft. Between 250 and 350 men will be needed to man the big shop when it is completed early next year.

—

Ford to Build Plant in England

DETROIT, MICH., Oct. 9—The Ford Motor Co. of Detroit states that the Ford Motor Co. of England, a separate corporation, will shortly erect a large plant near Southampton, England, for the production of Ford cars. Construction will be in charge of L. D. Perry who sailed for England on Oct. 6. The general details of the new factory have not yet been arranged and will be planned by Mr. Perry after his arrival.

—

Waupun Co. Builds Bodies

WAUPUN, WIS., Oct. 9.—The J. S. Morris Co., Waupun, Wis., carriages and vehicles, is now specializing in the manufacture of special motor car bodies, such as hearses, limousines, coupés and other types. Several hearse bodies were delivered during last week and orders for similar bodies are on the books and will require maximum production for 5 to 6 months to fill.

—

Chase Truck Makes Changes

SYRACUSE, N. Y., Oct. 7.—The Chase Motor Truck Co., this city, has appointed L. H. Abbott assistant sales manager. Mr. Abbott was formerly manager of the service department.

C. N. Gillette has been transferred to the New York City branch of the company. He was formerly traveling sales representative in the Southern territory.

—

No Trucks at Cleveland Show

CLEVELAND, OHIO, Oct. 9—There will be no trucks in the coming Cleveland automobile show to be held at the coliseum beginning Dec. 30.

The decision, which was announced to prospective exhibitors last week, is believed to mean a greater variety of passenger car exhibits and it is thought will bring more interest to the vast majority of persons attending the show.

—

Aprahamian's Sailing Date Was Earlier

NEW YORK CITY, Oct. 7—In THE AUTOMOBILE for Oct. 5 it was stated that A. Aprahamian would sail last Saturday for Africa and the Orient to represent American automobile and acessory companies. This was misleading, as Mr. Aprahamian's sailing date was nearly 2 months ago.

Co-operation Is Open Week Slogan

St. Louis Dealers Work Together To Interest Public in Cars —Some Sales

ST. LOUIS, MO., Oct. 9—Automobile Open Week closed at 10:30 Saturday night. Practically all of the firms who participated call it a success. Joseph A. Schlecht, chairman of the show committee of the Automobile Manufacturers' and Dealers' Assn., says that the effort has proved a very satisfactory substitute for the Fall show, which has been the rule in St. Louis. On two evenings the salesrooms were thronged to capacity and there was a fair daily attendance. Scores of country dealers were on hand.

But the best feature of the week was the spirit of co-operation that was developed. Those members of the association whose salesrooms are not on the row and who could not lease temporary quarters for the week were housed rent free by members who had large quarters. The visitors were permitted to bring their salesforces to the hosts' salesrooms and place their swinging signs on the fronts of the buildings. Also most of the dealers kept an automobile in front of their stores and should a visitor, after looking over the cars displayed there, express a wish to see another car, the car was placed at his disposal.

All Co-operate

There also was an agreement as to signs, all being exactly of the same design and stating only: Shown Here—name of car—and below: Open Week, 1916.

Two parades were given, each car carrying a card giving its name and price. This parade toured the principal part of the city and by noon reached the fair grounds where the machines were parked for the afternoon in a special space set apart. On Thursday afternoon the attendance at the fair was given as 30,000 and practically all of them looked over the cars.

Some Sales Made

There was some business done, cars being sold mainly to prospects brought to town by country dealers and who insisted on driving their new cars home. Other visitors who were greatly appreciated were out-of-town folk who came alone to see cars and then inquired how soon their local dealer could get this or that model.

The real occasion for Open Week is this: For 39 years a mysterious organization has given each year during the first week in October an illuminated parade called the Veiled Prophet.

This has drawn thousands of visitors to town and when the first automobile show was organized this week was selected because of the many out-of-town visitors. Recently there has been an agricultural fair the same week. This fair is new and is handicapped by a lack of buildings, so the fall show could not be held there and this year the dealers wanted to get into the national circuit, so they decided upon the choice of Open Week.

—

Perfex Radiator Erects New Plant

RACINE, WIS., Oct. 7—The Perfex Radiator Co., Racine, Wis., one of the largest manufacturers of pleasure and commercial car and tractor radiators and cooling systems in the Middle West, on Oct. 9, began operations in its new factory at Holmes and Fleet Avenues. The new shop was dedicated on Saturday evening, Oct. 7, with a social party for employees and their families and friends. The factory is 75 by 255 ft. in size, and considered a model of factory lighting and sanitation. The capacity is increased to 400 radiators a day by the improvement. The Perfex company was established in Racine about 4 years ago and has met with much success. At present its orders are of such volume as to insure a continuous capacity run until the end of next year. More than 150 skilled men are employed at this time. The new plant represents an investment of $45,000 to $50,000. Officers of the concern are: President, F. M. Opitz; vice-president and treasurer, E. P. Wolf; secretary, J. P. Wolf.

—

U. S. to Mark Mojave Desert

DETROIT, MICH., Oct. 9—Following efforts of good road enthusiasts for the past fourteen years, the government has just appropriated $10,000 for the erection of sign posts to water holes in the Mojave desert. The desert has recently been traversed from the east by many auto drivers who found traveling comparatively easy but complained of the need of water hole direction signs. The plan adopted by the government is not only to mark the highways but to also designate water supplies clearly and to keep them free from pollution as far as possible.

—

Tractors Were of Latil Make

NEW YORK CITY, Oct. 7—The makers of the Latil tractor have written saying that in THE AUTOMOBILE for Aug. 24, on page 311, and again on page 314, the two illustrations which were stated to be Renault tractors were Latil machines. The Latil tractor was one of the first made in France and is one of the most successful. The French army is using many Latil and also many Renault tractors.

Sixteen-Month-Old Organization Holds Successful Convention in St. Louis

ST. LOUIS, MO., Oct. 6—The most successful convention of the National Assn. of Automobile Accessory Jobbers closed here to-day. It had a larger attendance, there was more enthusiasm and greater progress was made than at any session held in the brief career of the organization. The growth of the association is phenomenal so far as the automobile trade is concerned, for it has attained national proportions in 16 months.

Throughout the session there was evidence of a better spirit of co-operation. Members seemed disposed to work together for the common good and standards of practice were accepted upon a vote of the majority.

Trade Abuses Discussed

There were no idle addresses and little time was wasted under the direction of Commissioner William M. Webster. According to the system followed abuses in the trade are taken up, are discussed, referred to a committee, the committee's recommendation is discussed and action follows.

Monday and Tuesday were devoted to meetings of committees and directors and open sessions for all members were held Wednesday, Thursday and to-day. The entertainment program included a theater party Monday evening, attendance at the Veiled Prophets Parade Tuesday evening, a luncheon by the Business Men's League Wednesday, an automobile ride for women visitors Thursday to Shaw's Botanical Gardens, a banquet at the Sunset Inn Country Club, Thursday, given by the Curtis Pneumatic Machine Co., the McQuay-Norris Mfg. Co. and the Shurnuff Mfg. Co., a shopping tour Friday morning for the women, and a golf tournament Saturday.

An address on Business Co-operation was made Wednesday by Charles Nagel, former Secretary of the Interior, and H. G. Wilson, Traffic Commissioner of the Toledo Commerce Club, discussed Traffic and Transportation.

New Members

Thirty-four manufacturing members were admitted and 10 jobbing members. The jobbers' list is augmented by these members and by the Auto Supply Co., of Milwaukee.

The standards of practice set up will make much for the accessory trade. The principal recommendations follow:

The practice on the part of newspapers of using a car distributor as bait for participation in a blanket ad by the distributors' dealers was condemned.

Following an address by J. C. Thorpe, of the National Automobile Trade Assn., it was voted to work for greater co-operation with the retail organizations.

A committee was formed to investigate overhead expense.

Manufacturers were urged not to place excessive guarantees upon their goods.

Further emphasis was placed on the advisability of charging 10 per cent on returned goods.

The car manufacturer was taken to task for buying more accessories than he needs for car equipment and disposing of them at low prices to his branches and dealers. Trade directory publishers were urged to co-operate with the jobbers in compiling jobber's lists.

Jobbers were urged not to supply catalogs to dealers because this often enables the dealers to secure jobbing prices and he thereupon is able to sell at a figure so low that it upsets the trade.

Standardization of shipping and packing was urged and it was recommended that there be a movement among manufacturers toward small shipping units. Manufacturers were requested not to give prizes to the salesmen of jobbers, because this tends to upset the jobbers' regular business.

The committee on assisting the trade presented plans for the uplift of the retail division of the industry and was authorized to spend $1,000 in advertising.

A telegraph code was adopted.

It was suggested that manufacturers, when the goods are salable, repurchase bankrupt stocks and prevent the market being flooded with standard goods at ruinously low prices. It was the sense of the meeting that rebates should not be allowed to dealers.

On the question of payment of bills, dealers were urged to conform to the terms of the purchase agreement regardless of whether there is a cash discount, and manufacturers were urged to put their business on a more or less uniform discount basis.

Auburn Adds Four-Story Building

AUBURN, IND., Oct. 9—Work has been started on a four-story building for the Auburn Automobile Co. The building will be constructed of cement block and brick. The contract calls for its completion Nov. 1.

—

Mail Driver Must Obey the Law

BOSTON, MASS., Oct. 7—It cost Roland S. Ford, driver of a United States mail wagon, $10 in court to learn that he was not exempt from the automobile laws at Boston yesterday, and before the Highway Commission gets through with his case next week, when he has a hearing,

he may find his privilege to drive has been revoked. Ford has been driving a motor truck owned by the Boston Delivery Co., but leased to carry mail, and while going along Boylston Street, where it was muddy, he seemed to delight in creating splashes. The judge found him guilty of driving his machine in an unreasonable manner and refusing to show his license to the policeman, and he was fined $5 on each count. The Highway Commission was notified, and Ford has been summoned before that board for a hearing.

—

Hood Bureau Increases Scope

DETROIT, MICH., Oct. 10—The Wallace C. Hood Service Bureau, this city, has increased its scope by securing agencies for dealers, by assisting the dealer or manufacturer in solving merchandising problems, analyzing territorial conditions, obtaining executives or workmen, and acting in an advisory capacity.

F. M. Eldredge has recently become associated with the Hood bureau of Detroit in the capacity of director of the bureau's advertising and publicity divisions. Mr. Eldredge will continue his present connection with various large industrial concerns as manager of their publicity departments.

—

Thirty-three Entries for Chicago 250-Mile Race

CHICAGO, ILL., Oct. 10—Special Telegram—Thirty-three entries have been made for the 250-mile Grand American Automobile Race in this city next Saturday on the Speedway. Additional nominations are expected in later mails. All the prominent drivers and cars are included except the Sunbeams.

The race will probably settle the A.A.A. championship, as Aitken, Resta, Rickenbacher and DePalma are very close. As the winner of Saturday's race will be credited with 800 points, any one of the four to win will take the championship. Practice begins today.

$1,118,981 Fees for First 9 Months of Year—452 Makes

BOSTON, MASS., Oct. 7—The demand for registrations for motor cars continues to increase so that now the figures show a continual gain over other years. Despite the fact that those who waited until Oct. 1 could register their machines at half price very few waited.

For the first 9 months of 1916 the Highway Commission received $1,486,000. For the entire year of 1915 the receipts were $1,118,981, so there is little doubt but what the $1,500,000 mark will be reached this year as prophesied early in the year. The total number of registration certificates issued for the 9 months of this year reached 125,524. According to the figures compiled by the New England Auto List officials the cars were listed as follows:

Ford	27,895	Little	105
Buick	8,169	Allen	104
Overland	7,333	Baker	95

Ramsden Is Oakland Branch Manager

DETROIT, MICH., Oct. 4—J. H. Ramsden has been appointed to succeed E. J. Kilborn as manager of the wholesale branch of the Oakland Motor Car Co. in Cbicago. Mr. Ramsden joined the Oakland organization a few months ago. He was previously prominently connected with the farm machinery industry of the Middle West and for the two years before his association with the Oakland company he was manager of the St. Louis branch of the J. I. Case Plow Works.

—

Leach Gets King and Dort

LOS ANGELES, CAL., Oct. 7—The Leach Motor Car Co. has bought out the English Motor Car Co., and will handle the King and the Dort cars on the coast. The cars will be marketed through the former English company's organization, which has been continued practically intact by the Leach company.

—

Makes Industrial Moving Pictures

NEW YORK CITY, Sept. 23—The Animated Advertising Corp. of New York is preparing for manufacturers moving picture films of their products in use and syndicating these films through a large chain of moving picture theaters. A number of films have been prepared for manufacturers of automobile commodities who are clients of the Animated Advertising Corp.

—

Machine Tool Makers Add

MILWAUKEE, WIS., Oct. 7 — The Kearney & Trecker Co., manufacturing mining machines and other machine tools, is building a new smithing shop and otherwise increasing its capacity.

Globe Business Gains 40 %

Machine and Stamping Co.'s Output 1000 Boxes Per Day —Adds to Plant

CLEVELAND, OHIO, Oct. 5.—The Globe Machine and Stamping Co., this city, maker of tool and battery boxes, of which its output is now about 1000 boxes per day, reports a 40 per cent increase in business during 1916, the total business amounting to $600,000, or 100 per cent better than 1914. This company also manufactures hose clamps and universal joint cover clamps for the automobile trade as well as a line of special stampings and pressed metal parts to order, the latter amounting in volume to about $1,000 worth per day.

Additions Planned

The present factory now contains 80,000 ft., having recently been enlarged by a second-story added to the tool box building, 165 by 100 ft. New machinery has been installed during 1916 valued at $20,000. The company this year has also bought an acre of land near its factory, and is now adding a brick and concrete construction materials storage building. The ground floor of this building will contain about 10,000 sq. ft. Space is reserved around the sides of the plant for an L-shaped factory to be erected later, each wing of which will be about 200 by 60 ft., three or four stories in height.

Colfax Mfg. Buys Top Co.

SOUTH BEND, IND., Oct. 7—The Frederick W. Loomis Co., manufacturer of automobile tops, has been bought by the Colfax Mfg. Co., this city.

—

Business Good in Texas Despite Low Cotton Crops

DETROIT, MICH., Oct. 5—The automobile and accessory business has been excellent throughout the State of Texas despite a cotton crop that is two-thirds of the usual quantity, according to G. F. Bischof of Brownwood, Tex., who is at present in Detroit on matters in connection with the automobile business in which he is interested.

"The farmers have gone into the growing of wheat and oats and the raising of sheep and goats," said Mr. Bischof, "and by this means have more than offset the low cotton crop. My county had 445 Ford cars last year and has added more than 500 in the past twelve months."

The Ford agent in Brownwood is sold up to Jan. 1 and has refused to take additional orders until he fills those now on hand.

—

McGraw Tire Capital Increased by $1,000,000

EAST PALESTINE, OHIO, Oct. 7—The McGraw Tire & Rubber Co. at stockholders' meeting increased its capital stock from $3,000,000 to $4,000,000. One million dollars of the new preferred has been underwritten by the M. H. Murch Co., Cleveland. Present outstanding issue of $475,000 preferred is being redeemed in full by payment at par and premium of $10 per share.

—

Anderson Steam Vulcanizer Co. Formed

CINCINNATI, OHIO, Oct. 7—The Anderson Steam Vulcanizer Co., has been incorporated with $100,000, to manufacture steam vulcanizers. Incorporators are: Edward D. Woodward, Newton M. Anderson, Wm. D. Schwarting, Eugene Schmidt and J. C. Wells.

—

Market Changes Slight

NEW YORK CITY, Oct. 10—Market prices remained for the most part unchanged last week. Activities in the metals, as usual, were mainly on future sales, spot sales being very scarce. The only product affected by the submarine incident was rubber, Para going up 1 cent a lb., while Ceylon rose 4 cents for the week and 2 cents yesterday. Tin naturally rose on news of the sinking of certain ships, its price going up to $43.00 yesterday, or $3.62 per 100 lb. for the week. The rest of the materials were steady in prices.

Security Price Decline

Submarine Incident Affects Prices—Unlisted Motors Show Largest Losses

NEW YORK CITY, Oct. 10—A period of liquidation set in on Monday at the Stock Exchange and Curb when news of the U-boat raid was received. Those selling short reaped a rich harvest on some of the automobile issues, whose recessions ranged from a fraction to 30 points. Goodyear Portage Rubber, Ajax and Paige-Detroit, were the only stocks out of nearly forty to withstand the heavy selling pressure and to come out with substantial gains.

An interesting point is brought out by the study of a few of the stocks and how they acted on the submarine news. Willys-Overland, for instance, under heavy buying pressure, had declined nearly 2 points before the news was announced. But instead of violently breaking on a declining market, the issue held steady and marked only a small loss for the week. This was also true of other issues on the Stock Exchange, especially Maxwell and Studebaker. In the Lusitania panic Studebaker went all to pieces, but yesterday it only declined 4 points.

Unlisted automobile and accessory issues did not act so well. Chevrolet declined 8 points, and Springfield Body 6 points.

Several of the issues on the Exchange, however, showed unusually large declines. These issues are selling at high prices and holders were for the most part heavily covered. General Motors common broke 30 points to 690; Chalmers dropped 15 points to 130; Packard went down 10 points; and Firestone Tire 10 points to 1120.

Several new issues will make their appearance on the Curb, these being Harroun Motors and Enger Motor Co. The latter company has listed 300,000 shares, par value $10.

—

Casing Head Gasoline Production Increased 53% Over 1914

WASHINGTON, D. C., Oct. 7—The production of raw gasoline from gas during the last calendar year increased 53 per cent over 1914, the casing head gasoline industry extracting 65,364,665 gal. of raw gasoline, a gain of 22,712,033 gal. An average price of 7.9 cents a gal. was received for the unblended product.

It is estimated 24,000,000,000 cu. ft. of natural gas was utilized in the manufacture with the average recovery of 2.57 gal. of gasoline per 1000 ft.

Oklahoma led in production, with more than 45 per cent of the total. Califor-

nia, West Virginia, Pennsylvania, Ohio and Illinois followed.

Gasoline Extracted from Natural Gas and Sold in 1915

State	Number of plants	Quantity (gallons)	Value	Average recovery of gasoline per 1000 cubic feet (gallons)
Oklahoma	63	31,665,991	$2,361,029	3.60

Dividends Declared

United States Ruhber Co.; quarterly of 2 per cent on first preferred and 1½ per cent on second preferred, payable Oct. 31 to holders of record at noon Oct. 14. No action on common dividend.

Cole Motor Co.; 3 per cent, making a total distrihution in 1916 of 23 per cent.

Falls Motor Corp., quarterly of 1¾ per cent, on preferred, payable Oct. 15 to stock of record Oct. 1.

Kelly-Springfield Tire Co.; quarterly of 4 per cent on common, payable Nov. 1, 1916, to stock of record Oct. 16.

Reo Motor Car Co.; 10 per cent cash, payable Nov. 1; declaration of dividend delayed 2 weeks on account of consolidation of Reo car and Reo truck.

Harroun To Build 24,000 Cars

Company Will Make Its Own Motors and Trim Its Upholstery

DETROIT, MICH., Oct. 6.—Directors of the Harroun Motor Co. entertained citizens of Wayne at the Detroit Athletic club Monday evening. The dinner was attended hy nearly fifty in all, including a numher of Detroit newspaper men. John Guy Monihan, president of the Harroun company, acted as toastmaster at the dinner.

The Wayne officials told of their plans to house the workmen and to accommodate the company in every manner possihle, and officials of the Harroun company outlined the progress made in the formation of the company and its financing. It became known that the entire capital covering an output of 24,000 cars for the first year is in hand, the stock of the company being underwritten in New York. Plans for the huilding of a large addition to the Prouty & Glass Carriage Co. plant, which the Harroun company has purchased, were revealed. It was also made known that the company will huild its own motors and trim its own bodies.

Bernhardt and Hacquebart Join Harroun

DETROIT, MICH., Oct. 9—H. O. Bernhardt, for 2 years production manager of the Pierce-Arrow Motor Car Co., Buffalo, has become production manager of the Harroun Motors Corp. Peter Hacquehart has resigned as construction engineer of the Maxwell Company to take charge of the Harroun huilding operations.

His first duties will include the erection of an addition to the Prouty & Glass plants now standing in Wayne. This addition will he 130 ft. by 900 ft. in size and will he one story high. It will he used for progressive assemhly, store room and motor factory and will thus allow the use of the Prouty & Glass plant for the painting and upholstering of bodies.

Hupmobile Visits Half the Capitals

DETROIT, MICH., Oct. 6.—The Hupmobile capital-to-capital car has passed through Bismarck, N. D., ticking off 5918 miles of the 20,000 mile journey and with one-half of the capitals visited hut only one-quarter of the journey completed.

The one hig delay encountered was between Pierre and Bismarck when the tourists met with a fog that made path-finding extremely difficult. Visits are now scheduled for Boise, Idaho, and Seattle, Wash.

B. F. Goodrich Co. Gross Sales May Reach $77,000,000

NEW YORK CITY, Oct. 10—A total over-turn this year of $77,000,000 may be reached hy the B. F. Goodrich Co., Akron. Actual shipment of products for the 8 months ending Sept. 1 amounted

approximately to $50,000,000, a gain of 40 per cent over the same period of last year, or stated in terms of 1915's total sales, the volume of goods billed to customers in the first two-thirds of 1916 was within $5,400,000 of gross sales for all of the 1915 year, up to that time high record. If the company can hold this 40 per cent gain, the total turn-over is expected to be reached.

In 1912 Goodrich did a gross business of $37,533,000.

Perfection-Stanweld Merger

(*Continued from page* 597)

1906 on a capital of $100 and was formed by Christian Girl and M. M. McIntyre. Five years later it was doing a gross business of $209,310 and 5 years after that its gross was $1,645,829. That was for the year ending June 30, 1915. For the year ending June 30, 1916, the gross business amounted to $3,200,000 and its net earnings for the first 9 months of the fiscal year was $282,811.

The Standard Welding Co. which makes steel tubing, rims for vehicle wheels, motorcycle and bicycle parts, motor vehicle rod assemblies and heaters, and does job welding, was incorporated in 1899. The company employs 2500 men and has a yearly output of approximately 50,000,000 ft. of tubing and 1,000,000 rims and bands. It is expected that the output of the combined concerns will be the same as the output of the present companies.

Officers of the Perfection Spring Co. are Christian Girl, president and general manager; E. W. Farr, vice-president; P. A. Connelly, secretary; T. E. Borton, treasurer. They together with F. F. Prentiss, C. C. Bolton and W. R. Clymer make up the board of directors.

C. W. Bingham is the president of the Standard Welding Co., H. P. McIntosh, vice-president and treasurer, and J. H. Champ, secretary. The board of directors comprises the officers and H. P. Bingham, H. P. McIntosh, Jr., C. C. Bolton and D. S. Blossom.

Giant's Despair Won by Chalmers

—

Junk, Pike's Peak Winner, Takes Free-for-All—H. A. L. Second—Other Events

WILKES-BARRE, PA., Oct. 7.—Fred Junk, winner of one of the events in the Pike's Peak hillclimb this year, captured the free-for-all event in the Giant's Despair hillclimb to-day by driving a Chalmers up the steep mountain course in 1 min. 41 sec., the best time over the course for the day. With this victory went the John Welles Hollenback trophy, that has been held by the Knox Automobile Co. since the Giant's Despair climb was abandoned several years ago.

An H. A. L., driven by Turcotte crowded Junk for the free-for-all honors, his time being 1:45 3-5. Third honors went to Hughson, in a Pathfinder, his time being 1:47. Dalton, driving a Packard, was fourth, covering the course in 1:50 2-5. Emerson, at the wheel of an S. S. E., a Philadelphia entry, took fifth place with a time of 1:57 2-5. Zwally, driving a Stutz, was sixth, his time being 2:10. Haines of Philadelphia, in a Mercer, came in seventh in 2:15 3-5.

In the opening event a Saxon car, the only one entered, developed engine trouble and was disqualified. In event No. 2, Durham, driving a Maxwell, went over the course for first place in 1:50. Junk crowded him close, and C. J. Rogers, of Philadelphia, driving a Lexington, finished fifth; time, 2:56 3-5. A Mercer, driven by Haines, captured the third event in 1:49. Durham, in a Maxwell, was second, and Emerson, driving an S. S. E., was third. Time, 2:05 3-5.

Forty thousand people were on the course when the races started. More than 4000 automobiles were parked along the mountain road. Despite the large crowd, not an accident of any kind occurred. The summary follows:

SUMMARY OF EVENTS

Event No. 1

Car and Driver	Time
Saxon—Roberts	Failed to finish

Christiaens Returns to England

NEW YORK CITY, Oct. 6.—Joseph Christiaens sailed yesterday for England on the *Finland*. He took with him the two Sunbeam racing cars he has been campaigning in America. Mr. Christiaens hopes to return next year after making a number of changes in design based on his experiences of this season.

—

Shields, Anderson's Mechanic, Dies

INDIANAPOLIS, IND., Oct. 9—Bert Shields, mechanician for Gil Anderson, who was injured when their car turned turtle in the recent race at the Cincinnati Speedway, died at his home in Crawfordsville, Ind., Oct. 1. Shields' back was broken. Anderson is recovering.

—

Eastern Canada Show Jan. 20-27

MONTREAL, QUE., Oct. 6—The 1917 National Motor Show of Eastern Canada will be held Jan. 20-27 in the Almys Building, this city. The entire floor-space will be 26,000 ft., all on the third floor.

A large automobile freight elevator will be especially erected for show purposes and there are six passenger elevators and four large stairways.

The 1916 Montreal show was held only in the basement of the same building.

—

Hollier Wins Wager Race

BOSTON, MASS., Oct. 7—As a result of a discussion relative to the merits of six and eight-cylinder cars between dealers at Houlton, Me., a race was arranged between a Hollier eight and a Chalmers six from Houlton to Boston, a distance of 363 miles, and it was run off yesterday. The Hollier was driven by Jake Wise, while A. D. Holyoke drove the Chalmers for George W. Boyer. The arrangements were that the first car to check in at the Adams House, Boston, should win a wager of $500. Both machines left Houlton at 7 in the morning. From that town in the northeast corner of Maine

Records Made in Giant's Despair Hill Climbing

Year	Car	Driver	Time
1906	English Daimler	H. N. Harding	2:11 1-5
1907	Matheson	J. B. Ryall	1:59 2-5
1907	Simplex Peugeot (Motorcycle)	W. H. Wray	1:40
1907	Stanley (Steam Car)	E. W. Harper	1:56 4-5
1908	Great Chadwick Six	Willie Haupe	1:38 2-5
1909	120 h.p. Benz	D. Bruce Brown	1:31 3-5
1909	Indian Motorcycle (7 h.p.)	W. H. Wray	1:41 2-5
1910	Fiat	Daiph De Palma	1:28 2-5

they raced down through Bangor, Portland, Portsmouth, Newburyport to Boston. Wise reached the Adams house at 8:30, in just 13½ hr. He had hardly time to announce his arrival when Holyoke drove up, and he was very much surprised to learn that he had been beaten by 10 min. Both men drove the entire distance without stopping to eat.

—

Suggests Precautions Against Fire

BOSTON, MASS., Oct. 7—Fire Prevention Commissioner of Massachusetts, has sent out some suggestions through the press as to what automobilists can do to aid in making garages safer, and in lessening the dangers from fire in structures where cars are handled. He says that many fires are the result of carelessness, and not paying attention to the laws governing such structures.

—

2 Months for Underspeeding

WORCESTER, MASS., Oct. 7—While thousands of motorists have been arrested and fined for fast driving in Massachusetts the first case where a motorist was brought into court for slow driving occurred here yesterday. Edward C. Smith of Leominster was before Judge Utley on a charge of driving so slowly that he obstructed traffic. Traffic Officer Lyman J. Gorton testified that Smith came along to Harrington corner, the busiest place in Worcester, and he drove his car so slowly that he held up traffic. He was sentenced to 2 months in the house of correction.

—

Two Receivers for Twin-City Speedway

MINNEAPOLIS, MINN., Oct. 7—The Twin City Speedway Assn. now has two receivers. The Hennepin county court has appointed Elijah Barton at the request of the Minneapolis Trust Co., representing the mortgage or bond interests. The previous appointment was in Ramsey county of P. W. Herzog in the interest of creditors. The new receiver has power to protect the property with watchmen and insurance.

—

Device To Prevent Car Overturning

COLUMBUS, OHIO, Oct. 9—The Shilling Automobile Bumper Co., Columbus, has been organized with a capital of $100,000 to manufacture a safety device to prevent automobiles from turning turtle when an accident happens, the invention of E. C. Shilling of Columbus.

E. C. Shilling is president and Jacob Dagger of Urbana, secretary-treasurer. It is planned to open a factory in the Buckeye capital to make the device which can be operated so that the driver instantly can throw heavy bars on either side, when there is danger of overturning.

Mechanics to Share in Race Prizes

—

New System of Distribution at Harkness Event—Special 50-Mile Race

NEW YORK CITY, Oct. 7.—A new system of prize distribution in which the mechanics will also come in for a share of the money will be started at the coming Harkness Trophy race on Oct. 28 at the Sheepshead Bay Speedway. A 50-mile special race for non-winners will follow the trophy event. It will carry $2,500 in prizes.

In addition to the $10,000 in prizes for the first six cars to finish the 100-mile race, $2,650 has been set aside to be distributed in lap prizes, 70 per cent of which will go to the driver and 30 per cent to the mechanician.

The bonuses will be awarded to leaders at the end of the various laps as follows:

Miles	Bonus	Miles	Bonus
10	$100	54	$50
12	50	56	50
14	50	58	50
16	50	60	100
18	50	62	50
20	100	64	50
22	50	66	50
24	50	68	50
26	50	70	100
28	50	72	50
30	100	74	50
32	50	76	50
34	50	78	50
36	50	80	100
38	50	82	50
40	100	84	50
42	50	86	50
44	50	88	50
46	50	90	100
48	50	92	50
50	100	94	50
52	50	96	50
		98	50

The regular prize money will be awarded as follows: First, $4,000; second, $2,500; third, $1,500; fourth, $1,000; fifth, $600; and sixth, $400.

—

Connecticut Registrations Gain 33 per Cent

HARTFORD, CONN., Oct. 7—Receipts for the present fiscal year from the registration of automobiles, motorcycles, trucks and individual drivers in Connecticut total $768,727.91, as against $536,970.09 for the corresponding period a year ago, or an increase of approximately 33 per cent. It is expected that the annual business will total $1,000,000.

—

Good Roads Day in New Hampshire

CONCORD, N. H., Oct. 6—Following a proclamation by Governor Spaulding designating last Saturday as Good Roads Day, various motor bodies busied themselves and with the granges doing their share the improvements on highways received a good impetus. At Nashua the automobile club celebrated the opening of the last link in the South Side highway, which joins it to Milford. The Milford Club also joined in the celebration. In Westmoreland, Lyme, East Kingston, Litchfield, Laconia, Londonderry and Keene special work was done. Members of the legislature made addresses and impressed upon the people that it was important to aid in building the smaller roads leading to the State highways.

—

Public Parking Spaces in Boston

BOSTON, MASS., Oct. 7—The Boston Street Commissioners have at last thrown open to motorists the first public parking place in the city, a small section of Boylston Street, where it will be possible to park some 50 machines. A part of Park Square nearby is also under consideration, where a dozen more cars may stand. There is no time limit on their stay.

Cars are allowed to stand against the curb in a few other places such as alongside the Boston Common and on a couple of other streets, but only for half an hour.

—

1897 Model Wins Haynes 12

KOKOMO, IND., Oct. 9—The award of the Haynes twelve, offered by the Haynes Automobile Co., this city, to the owner of the oldest car in America goes to Ed J. Howard, of Jeffersonville, Ind. Mr. Howard has an old gear-driven Haynes which he purchased at the factory in the summer of 1897. Since that time the car has been in his possession. After a 19-year period of service in the hills of the Ohio valley, the car is still in running condition. It was the oldest of 140 entries.

—

Brockton Outdoor Show a Success

BROCKTON, MASS., Oct. 6—New England's most pretentious automobile show for an outdoors exhibition held in connection with the Brockton Fair proved to be a success. More than 125,000 people visited the grounds.

There were 125 cars and trucks exhibited. While the greater number of spaces were taken by the Brockton agents, a few were paid for by the Boston dealers. There were forty makes of cars and eight makes of trucks, the latter not including the tractors. In the accessory gallery there were about twenty-five exhibitors.

—

Dimmers Required in Phoenix

PHOENIX, ARIZ., Oct. 6—An ordinance requiring the use of dimmers on automobile headlights, and requiring all drivers of motor vehicles to stop behind standing street cars has been adopted by the city commission under the "emergency clause" and is now in effect. The commission's action followed a series of accidents said to be due to the blinding glare of headlights.

Argentine Trade—Mark Law an Important Factor

(*Continued from Page* 629)

made the subject of a separate application to be paid for separately at the same price which before would have secured the mark for the entire mercantile gamut.

"Under the former ruling it became quite the custom for an applicant to claim all classes of goods, for the simple reason that he could do so without any additional cost. And for the same reason many foreign applicants, on sending their applications through their attorneys, found themselves in absolute control of their particular mark in this country, to the exclusion of all future applicants for the same mark for any kind of goods whatsoever. I venture to state that there are many British and American registrants of Argentine trademarks who are to-day in ignorance of the fact that no other person may register their marks for any class in the Argentine without their consent—a state of things which, quite possibly, they may have neither requested nor desired, and which was only brought about by the thoughtless action of the local attorney or agent.

Foreigners Worst Offenders

"From these circumstances there arose in a great measure the reputation of the Argentine as a trademark pirate, when as a matter of fact the foreigners have been the greatest sinners in this respect—not because the former is so much more upright than the latter, but rather because the greater part of the commerce and industry of the Argentine Republic is carried on by foreigners.

"Now the marks covered by what might be called 'blanket' registration previously to 1912 hold good up to the date of their expiry after a period of 10 years. Then they may be renewed for each or every one of the classes covered, and in the majority of cases this is being done for a limited number of classes, although some even now are willing to pay the registry expenses for each class in order to enjoy the absolute monopoly of their mark. Conditions are therefore becoming more favorable for the registry of foreign marks, and as time passes they will become even more so.

"The above-mentioned conditions have undoubtedly been taken unscrupulous advantage of in many cases, and there have been some notable instances of the legitimate owners of foreign trademarks being forced to pay exorbitant sums to secure the registry here.

"Nevertheless, in the majority of cases where it has been found impossible to register a foreign mark here it has been for natural reasons arising from the facts above indicated. For example, some time ago an American manufacturer wrote to the Argentine consulate: 'We have learned that our trademark has been pirated in the Argentine'; the fact being that the mark in question—the name of a mythological deity—has been registered and in use here by a local firm in the same line of business for more than 40 years, or some 10 years before the existence of its accuser.

Business Relations

"A phase of this subject which should receive earnest and impartial attention is that which refers to the relations between foreign manufacturers and their Argentine representatives. So little attention has been generally given to the appeals of the latter for protection by registry of trademarks that it has become almost the universal custom for any firm here, before making deliveries of an article bearing a new trademark or name, to register the same at once in order to forestall the unscrupulous action of anyone who might attempt to do so for speculative purposes. The foreign manufacturer is usually advised of such registry by the representative or agent, and in nine cases out of ten pays no attention to the offer of the latter to transfer the registry in consideration of reimbursement of the expenses incurred. As time goes by question may arise between the two parties, and the agent finds himself in possession of a defensive weapon which he had not thought of using for that purpose but which he believes himself justified in doing.

"Now, it is undoubtedly true that manufacturer and agent have or should have equal interest in building up a good business. It is equally true that although the manufacturer may act in perfect good faith, it is frequently impossible for him to give absolute protection to the agent, for the reason that the goods may be bought through commission houses and shipped to the agent's competitors without the knowledge of his principal. The only way to fully protect the local agent as the exclusive importer of his principal's product is to have the mark under which the goods are sold registered in his name. This can be done with perfect safety to the manufacturer by executing the proper document whereby the registry will revert to the manufacturer on termination of the agency contract.

"For example: If the foreign manufacturer makes a contract with an Argentine representative whereby the former is to ship his product exclusively to the latter, and if competitors here secure the same goods through other channels and put them on the market at cost or at least lower than the 'exclusive agent' can afford to do at a fair profit (a thing, by the way, which has been repeatedly done), the 'exclusive agent' has no redress whatever if the trademark under which the goods are sold is registered in the name of the foreign manufacturer, since in spite of the production in court of the exclusive agency contract the competitor, on proving that the goods sold bore the genuine trademark of the manufacturer in whose name it was registered, and that the goods were genuine, would be absolved by the court with costs to plaintiff.

"But if, on the contrary, the trademark is registered in the name of the local agent, he is then in a position to completely protect his interests in such a case, and incidentally the real interests of his principal. I would therefore recommend that in such cases the trademark, if already registered, be transferred to the agent during the period of the exclusive agency contract.

Too Much Protection

"But the question will naturally arise, Does registration of the trademark in the Argentine really give protection? And the reply is—*Too much protection!* I mean that the protection is so strong as to be dangerous when in unscrupulous hands. A few plain facts without any comment whatever will make this evident to the judicial mind. These are the facts:

"1. The penalty for infringement includes fine and imprisonment.

"2. The imprisonment is not redeemable hy payment of money.

"3. The suit is thus of a semi-criminal nature.

"4. *But suit may be withdrawn by plaintiff at any time before sentence is pronounced!*

"It is almost unnecessary to state, in view of the above, that the majority of infringement cases which might otherwise enrich Argentine jurisprudence never come to sentence.

"There are two notable exceptions to the general rule that first registry entitles registrant to the mark as against first use. Proper names and portraits of persons are protected to the fourth generation of the heirs, and the courts have repeatedly restored to the foreign claimant a registered mark containing or consisting of a proper name, or even the name of a company or corporation. The names of commercial firms doing business and duly matriculated in the Argentine are protected without being registered as trademarks, although it is quite usual to so register them or as a part of the mark. But foreign firms have no such common-law protection, and their names should be registered as trademarks or in connection with the same."

(Next week the various classifications for the trademark law will be given.)

Factory Miscellany

Metal Parts Company to Build—The Metal Auto Parts Company, Indianapolis, Ind., has completed plans for the erection of an $80,000 building.

Cadillac in Toledo—The Toledo-Cadillac Co., Toledo, Ohio, has taken a long lease on the building at the northwest corner of Madison Avenue and Eleventh Street, formerly occupied by the Lichtie Auto Co. and has occupied it as an exclusive salesroom for used cars.

Million-Gal. Pumping Engine for Firestone—The Firestone Tire & Rubber Co., Akron, Ohio, has placed an order with the Milwaukee works of the Allis-Chalmers Mfg. Co. for the manufacture and installation of a 1,000,000-gal. high-pressure pumping engine for its Akron shops.

New Upholstery Company in Chicago—L. J. Blumenthal, connected with the automobile and carriage trimming business for the past five years, has entered business for himself under the name of Blumenthal Brothers, to carry a line of automobile and carriage trimmings at 115 West Lake Street.

Westgard Plant Started—The Westgard Tire & Rubber Co. has started work on its plant in Warren, Ohio. The main building will be 140 ft. wide and 350 ft. long. Next to the main building the powerhouse, 40 by 40, will be built. Two hundred men will be employed at the start. This number is to be doubled in the near future.

Ind. Factory Activities—The South Bend Motor Car Co. has closed a deal with New York City whereby the South Bend concern is to build 10 fire trucks for the use of the metropolis. The trucks will be similar to those in use in South Bend.

The laying out of the foundation for the fourth building to be erected by the Bowser Oil Tank & Pump Works, Fort Wayne, this year has been commenced. The building will be used for storage purposes and will measure 80 by 150 ft.

The Advance-Rumely Co. of Laporte, Ind., is experimenting in the manufacture of an all-steel tractor. Heretofore considerable wood has gone into the construction of tractor bodies. Recently the possibility of manufacturing an all-steel tractor gained headway in the Rumely offices, and Chris. Nyberg, one of the company's draughtsmen, was detailed to the Battle Creek, Mich, offices of the company and help in the plans of getting out an all-steel tractor. Mr. Nyberg says he believes the experiment is a success since the work has been completed.

Wis. Factory Items—The Western Malleables Co., Beaver Dam, which introduced a line of automobile parts several months ago, to supplement its output of railroad and other malleable castings, is enlarging its facilities to properly accommodate the large volume of business being booked in both directions. The Elm Street plant at Beaver Dam is being enlarged by the erection of a 53 by 120-ft. addition, and a new core room, 90 by 26 ft., and a new sand shed are being added to the South Street plant.

The Osborne Casting Co., Racine, is the name of a new concern which is establishing a grey iron foundry in Racine to cater to manufacturers of automobile engines and complete cars. The backers are J. H. Osborne and C. G. Holmes, experienced foundrymen. More than $20,000 is being expended in the erection and equipment of a new foundry at Layard Avenue and the North-Western tracks, and this plant will be ready for operations on or before Jan. 1. Forty to 50 men will be employed at the start.

The Gillette Safety Tire Co., Eau Claire, will be ready to start manufacturing Nov. 1, according to present plans. The first unit of the new factory is now completed and the equipment and machinery is being installed. Ground has been broken for the office building, which will be 50 by 80 ft. in size and conform to the outline of the factory.

The Waukesha Motor Co., Waukesha, will break ground Oct. 15 for the erection of a new office building and draughting shop, to be 44 by 88 ft. in size, two-story and basement. The plant is being enlarged to accommodate the unprecedented demand for engines for pleasure and commercial cars and tractors.

TRACTOR

Oct 14-29—Dallas, Tex., Demonstration, Texae State Fair.

The Week in the Industry

Pomeroy Joins Michigan Motor Car Co.—B. H. Pomeroy, M.E., for several years connected with the Dayton Motor Car Co., The Mead Engine Co. and Rapid Motor Vehicle Co. as chief engineer and superintendent, has been appointed factory manager of the Michigan Motor Car Co., Detroit. Mr. Pomeroy was formerly connected with the DeDion-Bouton Motor Car Co. of Church Lane, Brooklyn, N. Y., also with the Locomobile Co. and the Mobile Co. in the steam car days.

Wiese Made Studebaker Branch Manager—J. S. Wiese has been appointed to be branch manager for the Studebaker Corp. at Buffalo. He succeeds J. O. Hahn, who formerly operated the Studebaker branch at Cleveland and who is now the treasurer of the Studebaker Sales Co., which is the result of the merger of the Blevins Auto Sales Co. of Toledo and the Davis Motor Car Co. of Cleveland.

Louisville Items—The Louisville branch of the Ford Motor Co. will discontinue selling cars and parts at retail.

Seven agents have been appointed to handle the Ford in this city. They follow:

Atlas Machine Co., 728 West Market; Browder & Hoskins, 628 South Third; Broadway Motor Sales Co., 1012 East Broadway; F. P. Harter, 1064 Bardstown Road; Louisville Motors Co., Jackson and Broadway; Monarch Auto Co., 206 East Broadway; Roy E. Warner Co., 928 South Third.

Canadian Trade—George Primm has been appointed the West End representative for the sale of Ford cars and has opened temporary show rooms at 4280 St. Catherine Street, West Montreal.

Clermont & Rousseau have opened Ford show rooms at 994 St. Denis Street, Montreal.

The East End Garage, 789 Berri Street, Montreal, have taken on the representation of the Stanley steamer for Montreal.

Hartford News—The R. D. Britton Co., Allyn and High Streets, Hartford, Conn., is to take over the second floor of the building now occupied when the Universal Auto Co. removes to the new concrete sales and service building on Allyn Street. It is expected that the change will be made about Dec. 1.

Charles Ledgard of the sales department of Metcalfe & James, 134 Church Street, Firestone distributors, has been appointed manager. He assumes the new post this week. R. B. Metcalfe of the firm has returned to New York and will remain there until next spring, when he will return.

The Reid Motor Co. is to take over the salesroom of the Hartford Buick Co. at 356 Main Street as soon as the latter concern can renovate the recently acquired Park Casino on Elm Street, which is to be a combined sales and service building. The Reid company will also take over a portion of the new Buick service building on upper Elm Street and will release the present salesroom at 278 Main Street.

G. H. Gabb, Hartford, Conn., Auburn, Haynes, Kelley truck and Smith Form-A-Truck representative, has removed his sales office to 278 High Street.

Nine manufacturers accepted the invitation of the Automobile Club of Hartford for a public demonstration of dimming devices at Charter Oak Park this week. Each device was given a separate trial, after which lunch was served by the club at the Allyn House. The various representatives then explained their devices.

Wash. Trade Activities—Realizing the importance of Tacoma as a trade center and distribution point for southwest and central Washington, the Firestone Tire & Rubber Co. has established a direct factory branch at 705 Commerce Street. It is under the management of E. A. Stewart.

Form May-Kelleher Co.—A. C. F. Kelleher and H. H. May have formed the May-Kelleher Co., Pittsburgh, and will handle Pierce-Arrow cars. Kelleher has for the last 4 years been connected with the Foss-Hughes Co., Philadelphia, Pierce-Arrow dealer.

Philadelphia Items—The Packard Motor Car Co. is having plans prepared for an eight-story concrete building to be erected at Broad and Wood Streets. It will measure 70 by 180 ft.

The Fanning-Mathis Co. has leased the garage in the new building now being erected at 1611-15 Vine Street, and will use it as a service station.

Oliver Brothers, 600 North Broad Street, Philadelphia, have added the Roamer.

Edward Wilkie has formed the Wilkie Motor & Supply Co. and will handle Buick sales in that city on an exchange car basis at 677 North Broad Street.

Ariz. Trade News—The Babbitt-Polson Co., Phoenix and Flagstaff, has been appointed Arizona agent for the Jordan cars, and will also act as distributor for New Mexico and part of west Texas. M. L. Burkhead, formerly with the Haynes sales agency of El Paso, has been appointed salesman by the Babbitt-Polson Co. in the territory mentioned.

Controlling interest in the southern Arizona Motor Co., Tucson, Buick agent, has passed from B. A. Snow to C. Edgar Goyette, S. E. Lannis, H. M. Hartley and F. E. Patterson. Goyette is president of the company under the new organization, and S. E. Lannis is car sales manager. H. M. Hartley will have charge of the tire and accessory department of the company.

Boston Changes—F. A. Hinchcliffe, for many years manager of the Winton Motor Car Co.'s branch at Boston, Mass., in charge of the New England district, has resigned to become agent for the Jordan car there.

P. L. McKinney, assistant manager of the Peerless company at Boston, has taken the Maine and New Hampshire territory for that line, with headquarters at Manchester, N. H.

Columbus News Items—W. R. Jones & Co. have taken the central Ohio distributing agency for the Prismolite headlight lens, made by the Standard Glass Specialty Co., Morgantown, W. Va.

Fred A. Walz, formerly a harness dealer at 325 South High Street, has opened a store to handle automobile tires and accessories at the same location.

E. W. Penton, connected with the Service Garage at 122 Fourteenth Avenue, has taken the central Ohio agency for the General Vehicle Co., maker of electric trucks.

The Ensign Motor Car Co., Springfield, Ohio, has taken the agency for the Empire in that city and surrounding territory.

Cruikshank, Son & Robbins, central Ohio agents for the Pathfinder and Briscoe, have moved into new quarters at 151-155 North Fourth Street.

New England Trade Items—Crosby Adams, who has just become manager of the Mitchell and Saxon agencies at Springfield, Mass., has taken on the Jordan car.

The S. L. Crosby Co., Bangor, Me., has secured the Maxwell agency for central Maine.

An agency for the General Motor trucks has been placed with the Western Massachusetts Cadillac Co., Springfield, Mass. It has three Massachusetts and one Vermont county.

The Grant Six car has been taken on by the Walter F. Kelley Co. at New Haven, Conn.

Brown-Lipe-Chapin Co. Sold

United Motors Buys Biggest Maker of Differential Gears in America

NEW YORK CITY, Oct. 16.—The Brown-Lipe-Chapin Co., Syracuse, N. Y., largest manufacturer of differential gears in America, has been purchased by the United Motors Corp. and the same policy with regard to the Brown-Lipe-Chapin Co. will be followed as is used by the United Motors Corp. with the several other concerns it has purchased. President Alfred P. Sloane, Jr., of the United Motors Corp., is authority for the statement that the general policy of Brown-Lipe-Chapin will be continued as at present but that the capacity of the plant in the manufacture of differentials will be doubled as soon as additional buildings can be erected. The large resources of the United Motors Corp. will give a broader foundation and scope to the Brown-Lipe-Chapin Co., and it is hoped to be able to manufacture differentials for all concerns needing them. President Sloane's name will be added to the board of directors of Brown-Lipe-Chapin, but H. W. Chapin will continue as general manager as he has in the past.

The purchase of the Brown-Lipe-Chapin Co. does not in any wise involve the Brown-Lipe Gear Co., of Syracuse, and which to date has been very closely connected with Brown-Lipe-Chapin. The Brown-Lipe Gear Co. is practically controlled by Messrs. Brown and Lipe, both

Moore Heads Western Spring Sales

NEW YORK CITY, Oct. 14—Kirk Moore has been appointed general sales manager of the Western Spring & Axle Co. For some time Mr. Moore has been production manager of the Vim Motor Truck Co., Philadelphia, previous to which time he was sales manager for Weston-Mott and Northway motors. The Western Spring & Axle Co. comprises the Cleveland Axle Mfg. Co., Canton, Ohio; Cleveland-Canton Spring Co., Canton, Ohio; Hess-Pontiac Spring & Axle Co., Pontiac, Mich.; Hess Spring & Axle Co., Cincinnati, Ohio; J. B. Armstrong Mfg. Co., Flint, Mich.; Cincinnati & Hammond Spring Co., Cincinnati, Ohio; Amsted Spring & Axle Co., Connersville, Ind.; Spears Axle Co., Wheeling, W. Va.; Champ Spring Co., St. Louis, Mo.

—

Coffin on Defence Commission

NEW YORK CITY, Oct. 12—President Wilson has named seven members of the Advisory Commission, associated with the Council of National Defense to study and suggest methods of increasing industrial and military efficiency of transportation and manufacture of munitions of war. The automobile industry is represented by Howard E. Coffin, other members being Daniel Willard, president of the B. & O., Samuel Gompers, President of the American Federation of Labor, Dr. Franklin H. Martin, Bernard Baruch, Dr. Hollis Godfrey and Julius Rosenwald.

—

King to Raise Car Prices

DETROIT, MICH., Oct. 15—The King Motor Car Co. will soon increase the price of its cars to take effect in about 60 days. The firm states it will soon be impossible to manufacture an automobile of the quality of the King eight-cylinder type to retail at $1,350.

—

Standard Parts Co. Merger Name

CLEVELAND, OHIO, Oct. 15—The corporation to be formed by the consolidation of the Perfection Spring Co. and Standard Welding Co. may be known as the Standard Parts Co. Seven per cent cumulative preferred stock may be offered at par or very close to that figure in the near future.

G. M. Corp. Capital $102,600,000

Readjustment Plan Approved —$82,600,000 Common and $20,000,000 Preferred

NEW YORK CITY, Oct. 16—The final organization of the new General Motors Corp. which has been effected under Delaware laws, reveals that the authorized capital stock will be $102,600,000. The formal approval of the readjustment plan which was first made public in THE AUTOMOBILE for Sept. 28 has been given by upward of 70 per cent of the holders of outstanding stock and has been forwarded to the shareholders of the General Motors Co. The plan has been signed by every member of the board of directors except J. A. Haskell, who is in Europe.

Readjustment Plan the Same

The readjustment plan is the same as was first made public. Of the total capitalization $82,600,000 is common stock and $20,000,000 is non-voting preferred stock, all shares having a par value of $100. The preferred stock is entitled to receive cumulative dividends at the rate of 6 per cent and is subject to redemption at the option of the company at $110 on Nov. 1, 1918, or any subsequent dividend date.

The distribution of stock in the Delaware corporation remains unchanged, shareholders of the General Motors Co. of New Jersey having the privilege of exchanging each share of preferred stock for one and one-third shares of new preferred stock, and one share of common stock for five shares of the new common stock. Deposits for exchange are to be made with the Guaranty Trust Co., New York, between Oct. 15 and Dec. 16 inclusive. The readjustment plan becomes effective Nov. 1.

Accessory Space Allotted

Stiger Succeeds Lovell as Assn. Pres. and Bradley Takes Sweet's Place

NEW YORK CITY, Oct. 14—Eighty-seven accessory concerns have been allotted space at the national shows in this city and Chicago. After adding sixteen concerns which will exhibit in this city only, the New York total thus far reaches 103. Twelve concerns will exhibit only in Chicago, thus making the total number to date there, ninety-nine. Last year New York was given eighty-seven and Chicago, eighty-three.

A meeting of the show and allotment committee of the Motor and Accessory Manufacturers was given yesterday at which space was given to 115 members, compared with ninety-five last year.

Several new companies will exhibit at these shows this year, including the following: A. B. C. Starter Co.; Au-To Compressor Co.; Detroit Weatherproof Body Co.; Evapco Mfg. Co.; Ferro Machine & Foundry Co.; Hall-Thompson Co.; Kokomo Electric Co.; Leather Tire

(*Continued on page* 681)

Olympian Motors Co. Formed

PONTIAC, MICH., Oct. 17—The Olympian Motors Co., this city, has been organized to build an automobile selling at less than $1,000. R. A. Palmer, prominent in the business activities of the Cartercar company, will head the new company and he will have asseciated with him as executives G. C. Bull, treasurer; C. E. Callender, secretary; and A. M. Stryker, advertising manager.

McClure Tire & Rubber Co. Formed

COLUMBUS, OHIO, Oct. 14—The McClure Tire & Rubber Co., which has been in business for about 3 years in East Gay Street, has been incorporated with J. A. McClure, Jr., president; E. Buchanan, vice-president, and Robert McClure, secretary and treasurer. A lease has been taken on a new building now in course of construction at 214-218 East Gay Street.

Thompson Is Miller Advertising Director

AKRON, OHIO, Oct. 14—C. S. Thompson has been appointed advertising director of the Miller Rubber Co., this city. Mr. Thompson was formerly president of the Thompson-Carroll Co., Cleveland.

Hutchinson Overland Branch Manager

TOLEDO, OHIO, Oct. 14—Guy Hutchinson has joined the Willys-Overland Co. to act as branch manager for Willys-Overland, Inc., New York City. Mr. Hutchinson was formerly sales manager and treasurer of the firm of Hart & Hutchinson.

G. M. Graham will assume the position of research and publicity manager for the advertising department of the Willys-Overland company on Nov. 1. Mr. Graham was formerly the sporting editor and automobile editor for the Philadelphia *North American*.

Manhattan Electrical Supply Reorganized

NEW YORK CITY, Oct. 14—The Manhattan Electrical Supply Co., this city, maker of the Red Seal battery, which was recently reorganized with an issue of $1,500,000 first preferred, $500,000 second preferred and $3,000,000 common, reports that all of the 7 per cent first preferred stock issued has been purchased.

Organize Truck Holding Co.

DETROIT, MICH., Oct. 13—Organization of a holding company in New York to be known as the United Truck and Equipment Co., with incorporation in Michigan, to operate the United Motor Truck Co., is being perfected. Other companies may be controlled by the holding company, possibly including the Republic Truck Co., Alma, Mich.

Capitalization of the new company will be more than $400,000, and it is understood that $60,000 or more will be stock without par value or practically common stock.

New Auto Parts Corporation

DETROIT, MICH., Oct. 14—The Canton Auto Parts Mfg. Co., Canton, Ohio, has been organized and incorporated with a capital stock of $300,000 to manufacture all kinds of automobile parts. S. S. Kurtz who is vice-president of the McCaskey Register company of Alliance, Ohio, and J. M. Kurtz are the principal stockholders. The company will be ready for operation about Oct. 24.

Eisenberg Is Scripps-Booth Engineer

DETROIT, MICH., Oct. 17—H. O. C. Eisenberg, formerly engineer of the S. G. V. Co., has been appointed chief engineer of the Scripps-Booth Corp., succeeding Charles A. Ericston, who has resigned.

Kopf Opens Chicago Office

CHICAGO, ILL., Oct. 16—M. G. Kopf has opened an office at 620 Chemical Building, Chicago, and will specialize in chemical electrical lines as applied to automobile engineering and patent matters. Mr. Kopf was formerly chief engineer of the McCormick Laboratories, Dayton, Ohio.

Lenox Co. To Make Tractors

Two Models at $4,500 and $2,000 Respectively—Passenger Cars Continued

HYDE PARK, MASS., Oct. 9.—Two tractors, one selling for $4,500 and the other for $2,000 represent what the Lenox Motor Car Co., with a plant at Hyde Park, Mass., is now building. They are to be known as the Lenox-American tractors. They will not interfere with the building of automobiles. The tractors were designed by R. B. Morton, whose father built the first ones made by the International Harvester Co. Additional capital has been brought into the company, President Howard having resigned from a big shoe concern to take the presidency.

The Lenox-American large tractor weighs 12,500 lb. The two big features of these tractors are the four wheel drive and four wheel steer. Self starters are a third. There is a three-speed transmission, patented worm and sleeve clutch and the same lever that operates the clutch also operates the brake. Another good feature is the control lever that takes the place of the governor. This little lever drops into a notch and takes up the speed of the engine. The operator steers the axles, not the wheels. The big tractor was made to turn in a circle the inner diameter of which was less than its own length of 16 ft. The steering gear is not of the ordinary cast type, but is worm and gear run in oil. The drive chain performs like a belt.

Axles are semi-floating and packed in grease. The power is transmitted direct from the driving axles to the face of the four lightweight drive wheels by pull rods so that none of the driving strain comes on the spokes. The wheels of the big tractor are 60 in. high, with 18 in. face, and the smaller are 48 by 10 in.

Two levers control the tractor. One is used solely to shift gears. With the other first the clutch is released, then the throttle closes and last of all the brake is applied. On the reverse motion of this second lever the brake is released, engine speeded up and the clutch engaged.

The company plans to build about 300 of the tractors the first season.

Wilson Takes Over Sales Duties

DETROIT, MICH., Oct. 17—George D. Wilson, production manager of the C. R. Wilson Body Co., has also assumed the duties of sales manager. Charles F. Barth has been appointed works manager of the company.

Crankshaft Corp. Issues Stock

2500 Shares 7 Per Cent Preferred and 7500 Shares of Common

DETROIT, MICH., Oct. 16—The Automobile Crank Shaft Corp., which recently absorbed the business of the Auto Crank Shaft Co., has authorized the issue of stock amounting to $250,000, which is divided into 2500 shares of 7 per cent cumulative preferred stock, par value $100, and 7500 shares of common stock of no par value.

According to a statement issued by James M. Hibbard, secretary and treasurer of the corporation, the company will manufacture 72,000 crankshafts this coming year, which is less than one-third of the business offered, the records showing that, because of limited capacity, the company was forced to refuse 153,000 shafts.

Provision is now being made to at least double the capacity of the plant by February, 1917. Present customers include over twenty-five of the most prominent concerns in the automobile industry among whom are Studebaker, Stutz, Stearns, Winton, Peerless, National, Mercer, Locomobile, Hupp and Cadillac.

The net earnings of the company are 300 per cent in excess of those of 1914 and equal to eight times the maximum amount of dividends upon the preferred stock. The directorate includes among its members: A. R. Demory, vice-president of the Timken-Detroit Axle Co., and Henry H. Sanger, vice-president of the Hayes Mfg. Co.

AUTOMOBILE CRANKSHAFT CORPORATION STATEMENT FOR 8 MONTHS ENDING AUG. 31, 1916:

Assets		
Land and buildings		$56,397.85
Equipment, tools, furniture, fixtures and machinery		186,672.63
Less reserve for depreciation	$2,938.58	
Work in process (labor and overhead expense)		16,845.20
Factory materials and supplies		6,748.37
Accounts receivable (customers)		70,719.27
Less reserve for doubtful accounts	16,323.40	
Insurance premiums unexpired		100.12
Prepaid taxes		1,444.96
Total assets		$342,878.79
Liabilities		
Preferred stock—7 per cent cumulative—2500 shares, par value $100		$250,000.00
Balance represented by 7500 shares of no par value common stock		65,565.41
Accounts payable—trade creditors		18,394.99
Bills payable		None
Accrued salaries and wages		7,431.74
Accrued liability insurance		486.41
Reserve for Federal income tax		1,000.00
Total liabilities		$342,878.79

Woodruff Is Simplex Sales Manager

NEW YORK CITY, Oct. 18—A. A. Woodruff has been appointed sales manager of the Simplex Automobile Co., succeeding R. M. Barbour, resigned. Mr. Woodruff joined this company this year as manager of the body department. Later he became assistant sales manager. He has been in the automobile field since 1900, when he formed the Woodruff Mfg. Co., to build automobile bodies, later becoming connected with the E. R. Thomas Motor Co., later becoming producing manager. In 1912 he became eastern sales manager American Motors Co. and the Lexington-Howard Co. as manager.

Henry Splitdorf Dead

NEW YORK CITY, Oct. 17—Henry Splitdorf, inventor of the magneto bearing his name, died in his home in this city yesterday at the age of eighty-two. His eldest son, C. F. Splitdorf, is head of the Splitdorf Electrical Co., Newark, N. J.

Mr. Splitdorf was a native of Germany. He was the pioneer of telegraph instrument makers, having made them for Professor Morse, the inventor of telegraphy. Mr. Splitdorf was the inventor of the liquid insulation of the magnetic wire.

Agnew Directs Chalmers Advertising

DETROIT, MICH., Oct. 17—W. L. Agnew, who resigned as advertising manager of the Hudson Motor Car Co. some few months ago, to accept the position of assistant manager of the sales promotion department of the Chalmers Motor Co., has been appointed advertising and publicity director of the Chalmers company.

Tisch to Make Dean Knife Timers

DETROIT, MICH., Oct. 13—The Tisch Auto Supply Co., Grand Rapids, has purchased the Dean Knife timer for Ford car rights and will manufacture them under the supervision of W. B. Dean.

Pa. S. A. E. Meets Oct. 26

PHILADELPHIA, PA., Oct. 14—The first meeting of the Pennsylvania Section of the Society of Automobile Engineers for the season of 1916-17 will be held at the Engineers' Club, 1317 Spruce Street, Philadelphia, on Thursday evening, Oct. 26. Herbert Chase, chief engineer, Automobile Club of America, will speak on "The Otto Cycle versus Constant Pressure Cycle For Automobile Engines."

This meeting will be the last of the current administration year and the annual election of officers will be held.

Doble Paper on Steam Automobile

CLEVELAND, OHIO, Oct. 13—Abner Doble, designer of a steam automobile bearing his name, will deliver a paper before the local section of the Society of Automobile Engineers on Oct. 20, covering his work on the steam car.

S. A. E. To Discuss Aluminum

Paper By J. E. Diamond Treats Exhaustively on Use for Automobiles

NEW YORK CITY, Oct. 18—A paper entitled, "Aluminum and Its Use in Modern Aeroplane Motor and Motor Car Construction," will be read by James E. Diamond before the Metropolitan section of the S. A. E. here to-morrow night at its opening session of the season. Mr. Diamond is consulting engineer, Aluminum Castings Co., Cleveland, Ohio.

The introduction to Mr. Diamond's paper touches upon the abundance of aluminum, pointing out that aluminum in nature is more abundant than any other metal and that it constitutes approximately 8 per cent of the earth's crust. The discovery of aluminum is touched upon, this happening shortly after the beginning of the nineteenth century. Mention is made of the progress made in the methods of reduction from time of Woehler to the year 1886, when electricity was first utilized in reducing the ores of aluminum.

The metallurgy involved in the reduction of aluminum by the process invented by Charles M. Hall is briefly sketched.

Some little space is devoted to a discussion of the physical properties of aluminum. The alloy field is covered briefly. The foundry likewise comes in for attention. The very great care necessary in the production of successful castings is touched on at some length. Such factors as furnace temperature, pouring temperatures are touched upon. A statement is made that there is probably no one factor of vital importance than the pouring temperature and "that casting which is barely escaped being a mis-run in the finished section due to a low pouring temperature is the best casting from all standpoints. Explanation for this is given. The need for supervision by technically trained men in every stage in the evolution of a casting is emphasized very strongly.

The employment of aluminum castings in motor car and also aero motor construction is considered. The employment of aluminum castings almost invariably for the larger units in the motor car is mentioned. These parts are, of course, the crank and transmission cases. The employment of the former in all cases where the cylinders and and crankcase are not cast integral is characterized as standard since only in one or two instances is material other than aluminum used for the case.

Regarding the transmission case, cost is cited as the only reason for the non-

(*Continued on page* 651)

Accept Four S. A. E. Standards Reports

Standards Committee Approves Miscellaneous, Tire, Aeronautic Engine and Truck Control Reports—Headlight Glare and Military Truck Specifications Feature Discussions

Special to THE AUTOMOBILE

WASHINGTON, D. C., Oct. 18—Meeting to-day at the Bureau of Standards, the standards committee of the S. A. E. received reports from nine divisions and placed several new standards on the books for presentation to the Society for mail vote.

Conspicuous are recommendations regarding headlamps, the final report of the research division on the standard form for fuel economy and acceleration testing, revised testing forms for use in determining engine performance and standard controls for trucks.

Dr. Stratton, in his address of welcome, urged that the S. A. E. make full use of the facilities of the Bureau of Standards for tests and research and made a strong plea for the adoption of metric standards wherever possible.

Speaking of standardization in general, he congratulated the society on being in a new field and able to profit by experience in older fields. He stated that co-operation between practical and scientific men is necessary in working out standards and emphasized the value of scientific testing to intelligent standards work. He also urged uniform international units of measure in both scientific and practical fields. He considers the metric system best and believes that a change to that system is not so difficult or expensive as many believe. Dr. Stratton cited the Bureau's work on porcelain in spark plugs as an instance of its value to the automobile industry, determining physical properties of porcelain and investigating refractories. He asked for suggestions for co-operative work by bureau.

The Morning's Work

In the morning the reports of those divisions on which little discussion was anticipated were taken up. B. D. Gray, Hess-Bright Mfg. Co., chairman of the ball and roller bearings division, presented a report standardizing medium series, one direction ball thrust and recommending standard stock sizes for aeroplanes instead of special sizes.

Another report presented during the morning was by Henry Souther, chairman of the recently formed aeronautic engine division. This recommended adoption of the European taper propeller soft end which the U. S. Army and Navy has adopted. It is now used on the Hispano-Suiza engine by Simplex. This was opposed by C. M. Manly, Manly Drive Co., on the ground that improvements will be made too soon to make standardization worth while. Mr. Souther proposed standardizing the 18-mm. plug for aeroplane engines as the S. A. E. plug does not stand up under severe punishment for some unknown reason. The matter is now being studied. He also advised the adoption of the electric motor definition of engine rotation and reported progress on horsepower per pound ratings.

Mr. Souther's report was accepted with the amendment that the taper shaft end be held in abeyance.

Colonel Squier, in charge of the aviation section of the U. S. Army, spoke on the advantage of close co-operation between the engineers and the government department, saying that America wanted to avoid Europe's mistakes in aeroplane engines and plane specifications.

Augustus Post, of the Aero Club of America, announced that a Pan-American Aeronautical Exposition will be held at the Grand Central Palace, Feb. 8 to 16.

Standard sizes for battery jars have been under consideration by the electric vehicle division for some time, and agreement is not yet reached, so this division presented only a progress report showing that the subject is likely to be cleared up finally before the Winter meeting.

Chairman Whitney reported progress to reduce battery jar sizes from 200 to 41 with 32 in one height, 9 in another and lamp sizes from a host to nine, all one base type, three sizes, and three voltages. Progress on rubber tire efficiency tests and sizes of charging cables is waiting for reports from other electrical societies on cables.

Miscellaneous Report Accepted

A very excellent report was presented by J. G. Utz, consulting engineer Perfection Spring Co., and chairman of the miscellaneous division. This division has a very full program and a number of difficult subjects before it. The report contains only two new recommendations in final form, one relating to spark plug terminal thread and the other to the extension of rod ends.

The division recommended that 15/16-in. hex size for spark plugs replace ⅞, as many makers now use it because it allows greater porcelain thickness while the same spanners fit it. Terminal threads should be in two sizes, 5-40, Ford size, and 8-32 as the S. A. E. standard, the 8-32 to be the A. S. M. E.

A taper socket and plug for fender irons in thread sizes from 7/16 to ¾, all tapered 4½ in. per foot, was also presented. The division also submitted two standards for steering wheel hubs, straight for those with levers on the top of the wheel and tapered for those not at the top. There are four sizes of each, ⅞, 1¾, 2, 2¼, taper of 1 in. per foot. It was also recommended that no extension of rod ends beyond ½ in. be made, as the larger sizes are not needed for strength, but only for wear, which can be provided on smaller sizes by hardening the pins. Mr. Utz's report was adopted.

Tire Division Recommendations

The tire division recommended straight side tires from 32 by 3½ to 36 by 4½, as the larger straight sides are not practical. The smaller ones are on Fords and therefore the soft bead clinches. J. E. Hale, experimental engineer of Goodrich Tire & Rubber Co., amended this recommendation with a provision that straight sides be of the wide standard. The report was adopted.

Prof. Gallup's report on Proposed Standard Form for a Complete Car Performance Test was presented. This was only a progress report for the research division and will be final in January. The report follows:

Proposed Standard Car Performance Test

1—The entire test shall be made upon an automobile speedway or other course surfaced with wood, brick, concrete, asphalt or an equivalent material. Such speedway or course must have been approved for this purpose by the Council of the S. A. E. or an agent authorized by it.

2—The entire test shall be conducted by a competent and impartial referee approved by the Council of the S. A. E. This referee shall have complete charge of the test and he shall select such assistants as he may deem necessary. The referee shall certify to the results of the test before a notary public, who shall affix his seal thereto.

3—The entire test, including the fuel economy runs and the acceleration runs, shall be performed between sunrise and sunset of the same day.

4—The entire test may only be run at a period during which no appreciable wind exists, i. e., no wind which at any time exceeds a velocity of 15 m.p.h., measured at the nearest U. S. weather bureau station. The average values of humidity and barometer shall be obtained from the same source.

5—During the entire test the car must be run with all tanks full and carrying its full complement of passengers or corresponding ballast. Full complement of passengers shall consist of one passenger or the equivalent for each seat provided, driver included. The average weight for passengers and driver is to be 150 lb. each.

6—During the entire test there must be no change in gear ratio, ignition, carbureter, or any other detail of the car or its equipment. This shall not be interpreted as prohibiting changing spark plugs or manipulation of spark and throttle levers.

7—When a car is stated to be a stock

car it must be stock in every particular. Even though different carbureters, ignition systems, gear ratios or other details are optional on the same stock car, no change shall be made during the entire test.

8—A car fitted with an inclosed body must have all windows and doors closed during the runs.

9—A car fitted with an open body must have the top up and windshield fully erected during the runs. Rear curtains must be fastened down. Side curtains must not be used.

10—The pressure in the tires shall be that recommended by the manufacturer of the tires used, corresponding to the load applied both front and rear.

11—The highest gear only is to be used during the entire series of runs.

12—At no time during the runs shall coasting, declutching or the use of brakes be permitted.

13—Oils and greases used in the engine, transmission, rear axle or other parts of the car must be of usual quantity and quality.

14—The whole of the fuel used during the test must be of one quality. A sample of the fuel shall be taken for the purpose of determining and recording its specific gravity. The trade name of the fuel used shall be given. Wherever possible, information relative to its heat value shall be furnished, also a curve showing the results of a fractional distillation test.

15—All fuel used during the test must be fed from the special tanks placed on the windshield. (See description of apparatus under Fuel Economy Runs.)

16—Previous to beginning any run of the test, the engine is to be operated sufficiently long to bring it to the normal temperature corresponding to the conditions existing during that run.

17—The entire cooling system must be fully operative during the test, both as regards air and water circulation.

18—From the beginning to the conclusion of the entire test (including both the acceleration and economy runs) there shall be no manipulation of any carbureter adjustments or control other than the throttle.

Fuel Economy Runs

19—The fuel economy runs, when conducted upon a speedway, shall be made so as to complete each run at a point identical with that of starting. Each run shall be made without any interruption.

20—When conducted upon a course approximately straight, the runs shall be arranged so that each shall be completed at a point identical with that of starting. In each run there shall be no interruptions except those necessary for turning. Any such course shall have an exact length of 5, 2½ or 1 2/3 miles in one direction.

21—The fuel consumption shall be measured at a series of speeds covering the entire range of the car from the minimum to the maximum, following in general the outline in the table:

Run	M.P.H.
1	Minimum speed
2	9-11
3	14-16
4	19-22
5	26-30
6	35-40
7	47-55
8	63-70
9	Maximum speed

Note: In case the maximum speed is less than that indicated in any of the other runs the latter shall be omitted from the test. In any event, however, a run is to be made at the maximum speed of the car.

22—Fuel shall be fed to the carbureter during the runs by gravity and shall be supplied from a weighing tank mounted so that the actual distance between the top of the float chamber of the carbureter and the bottom of the fuel chamber is not less than 12 in. The tank shall be such that the variation in head during a run shall not exceed 12 in.

23—There shall be two tanks, preferably mounted side by side, as shown in the accompanying sketch. These tanks shall be connected to the carbureter so that by means of two cocks or their equivalent one tank may be "cut in" and the other "cut out" simultaneously. Of these two tanks, one is a reserve tank, used for maneuvering when measurement of the fuel is not being made. This tank may be a fixture if so desired. The other is a weighing tank, to be used during the runs for the measurement of fuel. This must be capable of easy detachment so that it can be weighed and replaced without difficulty. It must be large enough to contain fuel sufficient to enable the car to complete its run at maximum speed without refilling.

24—The procedure relative to the tanks is as follows:

Each tank is to be filled with fuel.

After filling, the weight of the weighing tank with fuel is to be accurately determined and recorded. It is suggested that a carefully calibrated spring balance be used. Following this the weighing tank is to be mounted in position.

The engine and car shall be brought to the normal temperature and speed of the run before crossing the starting line on fuel from the reserve tank. Upon crossing the starting line the reserve tank shall be cut out and the weighing tank cut in.

When the course is such as to necessitate interruptions in the run due to turning, the same procedure shall be repeated at each end of the course.

Upon crossing the finish line at the conclusion of each run, the weighing tank shall be cut out. It shall then be removed from its attachment and with its contents carefully weighed. The weight of the fuel consumed having been recorded, the tank may be refilled and weighed again previous to the commencement of the succeeding run.

25—Before the commencement of each run a setting of the throttle shall be determined which shall give the average speed desired for the run. During the run this setting shall remain fixed. The time for each lap is to be checked by the observer and in no case must the time of the slowest lap exceed that of the fastest lap by more than 10 per cent of the latter.

Acceleration Runs

26—The acceleration runs shall only be made on a straight portion of the course.

27—Each acceleration run shall start from a constant speed equal to the minimum speed obtained in the fuel economy runs and shall continue until the maximum speed of the car is reached.

28—There shall be ten such runs made consecutively over the same course, reversing the direction each time. The data from each of these runs shall be recorded. The final result shall be the average of the ten runs.

29—In determining the acceleration an electrical timing apparatus shall be used. This shall provide means for making or breaking an electrical contact at definite and equal distances on the course.

30—From the record of this apparatus shall be obtained data showing in the form of a curve the relation between acceleration in feet per second per second and speed of the car in miles per hour.

It was pointed out in the discussion that no allowance could be made for pressure or vacuum fuel feed. Owing to the difficulty in determining what a stock car is, Herbert Chase, chief engineer of the Automobile Club of America, suggested the stock car clause to be omitted. B. B. Bachman, Autocar Co.; A. L. Riker, Locomobile Co., and W. H. Conant, Gould Storage Battery Co., strongly objected to the council approving referees or courses, since that would be an indorsement of results of tests which would lead to misuse of the society's name in advertising. Eventually the report was accepted as of progress, with clauses 1 and 2 referred back for reconsideration. A test will be made before the winter meeting to try out the method.

Headlamp Glare

In the afternoon headlight glare and truck standards were the chief subjects discussed.

The matter of headlamps and glare was opened by Chairman Clayden, who read the address given on pages 674 and 675 of this issue. Following it, A. L. Riker, chairman of the electrical equipment division, read the report of the work done since June, which follows:

Electrical Equipment Report

1—Most of the more important work of the electrical equipment division has progressed nearly to the stage at which final reports can be made. A revision of the matter on Data Sheets 38a is presented herewith with the final approval of the division; also a recommendation for taillamp glasses. Recommendations relating to details of headlamps are given in tentative form, final action on the details being withheld to await trial under manufacturing conditions. If no unexpected difficulties arise, final action will be taken by the division within the next 1 or 2 months.

Taillamp Glasses—2—Investigation has shown that practically all makers of taillamps are using glasses having a nominal diameter of 3 in. with tolerance of minus 1/64 and plus 1/32 in. It is recommended that these dimensions be made standard.

3—In view of the different forms of dust-proof devices, as well as the use of flat and convex lenses, it is considered inadvisable to standardize headlamp glasses.

Size and Location of Headlamp Bulb Filaments—4—The tentative recommendations in regard to size and form of filaments for headlamp bulbs are as follows:

5—The vacuum bulb shall have a filament in the form of a helix of 2.5 mm. outside diameter and 4.2 mm. long, the axis of the helix coinciding with the axis of the bulb, as in the sketch.

6—The gas-filled bulb shall have a V-shaped filament (each leg of the V being formed of a fine helix) lying in a plane passing through the axis of the bulb and at 90 deg. from the plane of the locating pins in the base, with the apex of the V pointing away from the receptacle. The

Bad Truck Measures for N. J.?

Recommendations of Special Committee Would Practically Bar Trucks from State

NEW YORK CITY, Oct. 16—It will be commercially impossible to operate a motor truck in New Jersey if the recommendations of the special committee appointed by William L. Dill, Commissioner of Motor Vehicles of that State, are enacted into law.

Among the most glaring of the absurdities with which the committee seeks to burden the motor truck operator is one that each truck driver must carry waybills for each load, these waybills to show the gross weight and net weight carried. Another is that all commercial vehicles shall carry spare wheels, so as to avoid the possibility of any part of the steel rims coming into contact with the surface of the road should the rubber tires become damaged.

Nor were these two recommendations the only ones the committee, which is formed of engineers of several of the counties of the State, seeks to impose.

It also would limit the width of any truck over 4000 lb. weight to 96 in., outside measurement.

Another suggestion is that the extreme length of motor trucks shall not exceed 23 ft. 6 in.

Another suggested statute would make it prohibitory for a motor truck to be equipped with any tire covering of metal, or with any lugs or hobs or other sharp devices which would be in contact with the surface of the road, except non-skid chains.

Still another is that not more than one trailer shall be allowed to any commercial vehicle and that in every case the trailer shall be equipped with rubber tires.

Nor is this all, for the committee seeks to increase the truck registration fees from the present maximum of $25 to a maximum of $125.

—

Prest-O-Lite Gets Injunction

INDIANAPOLIS, IND., Oct. 16—Judge A. B. Anderson in Federal Court last week granted a permanent injunction in behalf of the Prest-O-Lite Co., of this city against O. K. Stuart, of the Sun Lite Gas Co., Alexandria, Ind., which forbids the latter from refilling Prest-O-Lite tanks.

—

Kent Plant in Belleville

BELLEVILLE, N. J., Oct. 17—The Kent Motors Corp. plans to establish a plant in this city costing more than $500,000 with potential capacity for 50,000 cars a year. The plant will be 125 by 400 ft. Work will soon begin on three structures, a factory, power house and assembly building.

—

Pullman Leases Sphinx Plant

YORK, PA., Oct. 12—The Pullman Motor Car Co., this city, has leased the entire plant of the Sphinx Motor Car Co., and will use it for making bodies and other sheet metal parts.

First Photograph of a British War Tank

The above illustration is the first authentic picture of one of the caterpillar armored tractors used by the British Army on the Somme front in France. This machine has been injured by shell fire, or otherwise, as one of the elliptical belts which provide traction is torn out of position as shown at the right. Powerful gears revolve the belts and the weight of the machine is carried on rollers which are set close together on the ground side. The large wheels shown in the rear do the steering and support the weight of the tractor when crossing a shell crater or trench, thus greatly increasing its mobile length. Each machine is fitted with three or four machine guns and can fire 2000 bullets a minute, according to reports from the scene of operations.

Argentine Trade-mark Law—II

Definitions of Trade-marks and Copyright Classifications for the Automobile Industry

BUENOS AIRES, ARGENTINA, Sept. 15—There are several general considerations with regard to automobile trade-marks in the Argentina that should be kept in mind by U. S. A. automobile manufacturers in addition to those mentioned in THE AUTOMOBILE last week.

A trade-mark may consist of names of objects of persons in a special form; portraits, emblems, monographs, designs, borders, fancy words, letters, or numbers of special designs or forming combinations; containers or special form, etc.

Not registrable: Coats of arms, flags or other insignia of the Argentine nation. (By a recent ruling the coats of arms or flags of foreign nations may be registered by consent of the respective legation); the form of the product itself; the color of the same; terms or expressions which have become of general use; designations usually employed to indicate the nature or class of the products; immoral designs or expressions.

Procedure: On filing the application the description in duplicate accompanied by labels and an electroplate of the mark (not to exceed 3⅛ in. by 3⅞ in.) must accompany the petition, unless the mark consists of a "fancy word" only, in which case the electroplate may be omitted at option of applicant. The entire payment of Government fees for the term of 10 years is also paid ($50 Argentine) as well as the power of attorney in case the applicant is non-resident. The above mentioned fee together with the expenses of legalization and translation of power of attorney and $1 for each sheet of paper used during the entire prosecution of the case, including communications of the Office and replies to same, constitute the costs of the case, so that the agent or attorney who makes a fixed price is never sure of the exact amount of his profit, which at usual rates is little enough at the best. In case of rejection the first fee is returned at the cost of some more "stamped paper" and trouble on the part of the agent, or another mark may be substituted at a slight additional expense.

Publication: A few days after filing the mark is published during five consecutive days in the *Boletin Oficial* together with the name of applicant and the class of goods to be covered by the registration. After the last day of publication there is a statutory period of 30 days during which any persons deeming

Princess Cars in Production

Ten Cars a Day Present Output—$50,000 Worth of New Machinery

DETROIT, MICH., Oct. 17—Active production on the new models has started at the factory of the Princess Motor Car Co. The present manufacturing schedule calls for ten cars a day, and the product now being put out is provided in five different color combinations.

The line includes a five-passenger touring, three-passenger chummy roadster, and a raceabout. The cars are equipped with a Golden, Belknap & Swartz engine, with Grant-Lees clutch and gearbox. There is a floating axle of Princess design and 32 by 3½ tires. The bore and stroke is 3¾ by 4¼ and the chassis has a wheelbase of 108 in. Disco lighting and starting is used, this being a two-unit system. For ignition, a Splitdorf-Dixie magneto is fitted. Featuring the equipment is a fuse box on the dash which is unique in a car of this price. Another special point in the fitting of the car is that nothing but genuine leather is used in the upholstery.

The Princess plant has recently been completely overhauled and $50,000 worth of new machinery is just being installed. The new models which sell for $775 are being delivered regularly.

Willard Completes New Building

CLEVELAND, OHIO, Oct. 14—The Willard Storage Battery Co. has just completed the first of its new buildings at the plant located at 274 East 131st Street.

This building will be occupied by the forming rooms which have previously been located at the old plant, corner Marquette and Lakeside. The building contains 90,000 sq. ft. and is of the very latest and most approved type of construction.

Work has been started on the second building, which will be two stories and will contain 75,000 sq. ft. This building will be occupied by the factory office, machine shop and storeroom.

Mickim Heads Liberty Advertising

DETROIT, MICH., Oct. 17—Robert Mickim, formerly advertising manager of the Ford Motor Co. of Canada, has been appointed advertising manager of the Liberty Motor Car Co., to succeed H. L. Buller, whose resignation took effect last week.

Jordan to Double Capacity

CLEVELAND, OHIO, Oct. 16—Plans are now being prepared for the Jordan Motor Car Co. for the erection of a new building, which will double its factory capacity.

The Jordan company started deliveries Aug. 15, and to date have produced and delivered at the average rate of eight daily for the whole period, and the daily production now is ten.

The new building will be of the same size as the original, occupying 30,000 sq. ft. of floor space, and will be erected for occupancy late in the winter or early in the spring.

It is understood the new building will be used for body mounting and final assembling and inspection. At present the Jordan company is using a tent to take care of the overflow.

18,000 Grants for 1917

CLEVELAND, OHIO, Oct. 14—The directors of the Grant Motor Corp. met in Cleveland, yesterday, and declared the regular 1¾ quarterly dividend on preferred stock, payable Nov. 1 to holders of record Oct. 15.

The board passed on and authorized the building of 18,000 cars for the year beginning Feb. 1, and the production is expected to be 20,000 before 1917.

Velie Production Increased 300%

MOLINE, ILL., Oct. 17—The factory production of the Velie Motor Vehicle Co., this city, has increased 300 per cent. Four of the Velie buildings are now occupied by the passenger car department.

The increase in production of the truck department over that of a year ago is 260 per cent.

British Makers Fear U. S. A. Cars

Boycott Suggested—Must Keep Enlarged Car Plants Busy After War

LONDON, ENG., Oct. 7—The recent announcement that the Ford company would establish a plant in England has brought forth proposals to boycott the low-priced American car. It has been suggested that all cars not manufactured in the allied countries be excluded from the British markets after the war.

The war has been the cause for great factory expansion and though the plants at present are busy on munition work and are well equipped with tools and appliances for taking care of a large production, the future use of these immense buildings has been a great source of worry to the country. The British automobile industry is particularly well equipped for rapid production, and so there seems no reason why it should not, in a very short time after the war, produce the desired cheap cars so as to repel the American invasion.

British automobile makers hold that some such agreement should be reached on the ground that as soon as the war is over and freights drop to normal Europe stands a great chance of being flooded with cheap American cars selling from $250 upward.

Up to the present time the British au-

Jitneys Handle Overflow of Hyatt Workers

Jitney buses lined up outside the factories of the Hyatt Roller Bearing Co., Newark, N. J., to take the overflow of workers home. This line-up is a regular occurrence at the plant, morning, noon and night. Fares are 5 cents, and the buses have regular routes designated by signs which they carry. The Hyatt company is one of the units of the United Motors Corp. and employs 5000 persons

tomobile manufacturers have paid scant attention to the little car, for the reason that they have had more orders for their high-priced cars than they could execute. Conditions are changing, however, and the European trade is awakening to the possibilities of the low-priced car in that market.

—

Dividends Declared

Willys-Overland Co.; quarterly of 75 cents a share, payable Nov. 1 to stock of record Oct. 23.

Kelsey Wheel Co.; quarterly 1¾ per cent on preferred, payable Nov. 1 to stock of record Oct. 16.

Pennsylvania Rubber Co.; 1¾ per cent on preferred and 1½ per cent on common, payable Jan. 1 to holders of record Dec. 15.

Fisher Body Corp.; quarterly of 1¾ per cent on preferred payable Nov. 1 to stock of record Oct. 17.

Bower Roller Bearing Co.; quarterly of 15 per cent, making 45 per cent cash dividends so far this year. Also a stock dividend of 100 per cent recommended to be passed on at annual meeting in January.

Globe Rubber Tire Mfg. Co., semi-annual of 3½ per cent on preferred, payable Nov. 1, to stock of record at close of business Oct. 27.

Reo Motor Co., extra of 7½ per cent and quarterly of 2½ per cent, payable Nov. 1 to stock of record Oct. 16.

Nash Motors Co., initial quarterly of $1.75 per share on preferred, payable Nov. 1 to stock of record Oct. 20.

Hood Rubber Co., quarterly of 1¾ per cent on preferred, payable Nov. 1 to stock of record Oct. 27.

Bower Recommends 100% Stock Dividend

DETROIT, MICH., Oct. 14—After declaring a quarterly dividend of 15 per cent the directors of the Bower Roller Bearing Co. recommended that a stock dividend of 100 per cent be approved by the stockholders at their annual meeting in January.

Gasoline Pumps Are Inaccurate

—

Over 5,000,000 Gal. Lost in West as Result of Short Measuring

CHICAGO, ILL., Oct. 16—Two matters featured the gasoline situation in the Central West this week, one being a rather general drop in prices, and the other, charges of short-measuring pumps. In Chicago, gasoline is selling at 15.6 cents a gallon, which is a drop of 1 cent since the first week in October. The same price prevails at Milwaukee, the Standard Oil being the first to cut the price 1 cent which was met by the independents.

Reports coming from Bloomington and other Illinois cities indicate that the price of 15½ cents a gallon is rather general throughout the State. The city motorists now have to pay 16½ cents per gallon, whereas they were paying 17½ up to Oct. 10.

Approximately half the gasoline troughs that have been inspected in Chicago since June 12 have been condemned, 956 inspections having been made to date. Government inspectors are working with the city forces.

Results of an investigation of gasoline measuring pumps in Illinois made by the United States Bureau of Standards show that in tests conducted in Chicago and typical suburban and rural communities downstate, the Government inspectors found 82 per cent of the Chicago gasoline pumps, and 83 per cent of those outside Chicago, inaccurate. The average shortage was 3.9 cu. in. per gallon in Chicago, and 7 cu. in. per gallon downstate. It is estimated that this shortage means a loss of more than 5,000,000 gal. per year, or $1,000,000 at the present price of gas in Illinois. A tolerance of 0.1 cu. in. per gallon is allowed. Gasoline users in the Twin Cities are getting full measure according to a recent inspection of pumps in Minneapolis and St. Paul.

The Bureau of Standards of the Department of Commerce recently published a report pertaining to the accuracy of liquid measuring pumps in which it states the principal causes of short delivery are caused by leaks in valves or piping; formation of vapor due to excessive suction lift, or the introduction of air under the pistons; failure to correct for the inertia of a long column of moving liquid; the use of long filling hoses with a low connection at the pump making proper drains of holes an impossibility; operation of pump at less than full stroke; and slippage past valves and pistons.

—

New Polack Truck Tire Organization Formed

NEW YORK CITY, Oct. 14—The Polack Truck Tyre Corp. has been organized to take over the assets and business of the Polack Tyre & Rubber Co., Bridgeport, maker of solid rubber tires for commercial vehicles.

The new company is offering through E. B. Eames & Co., this city, 40,000 shares of stock at $12.50 per share out of a total capitalization of the company of 100,000 shares, no par value.

The refinancing plan provides the funds for the erection of a new plant. It is estimated that when the new plant is completed the company will earn about $3.50 a share. The stock, it is stated, will be listed on the New York Curb and the Cleveland Stock Exchange.

—

Massnick Mfg. Co. Now

DETROIT, MICH., Oct. 16—The Massnick Mfg. Co. is the new name of the Massnick-Phipps Mfg. Co. There has been no change in the stock ownership or control and the management remains the same.

—

Crude Oil Higher

NEW YORK CITY, Oct. 18—The materials markets last week were featured by a gain of 10 cents a barrel in Pennsylvania crude oil, which rose to $2.50. The principal purchasing agencies are continuing their efforts to bring to the refineries the large quantities of crude oil now in the hands of the producers, and as a result have raised prices to induce the holders to sell. It is stated that the producers are hoarding the supplies.

Steel prices still hold at $45 per ton on both Bessemer and open-hearth. Beams and channels quote at $2.87 per 100 lb. Automobile makers are actively in the market for soft steel bars for shipment over the first half of 1917. Much difficulty is experienced in having contracts accepted. Several of the Detroit makers are now in the market for about 50,000 tons of bars in the aggregate. All

the steel mills are filled up and can take little additional business except for delivery in the far future.

Crude rubber prices have softened after a temporary stiffening, due to the activities of the German submarine. Trading was light. Up-river is selling at 72 cents a pound, spot, while for November-December delivery the quotation was 68½ cents. The wide margin was said to be due to the fact that only one boat carrying Brazilian rubber is scheduled to arrive here this month.

—

Hoover Steel Ball Grows Fast

DETROIT, MICH., Oct. 16—The recent meeting of the directors of the Hoover Steel Ball Co. of Ann Arbor has revealed the phenomenal growth of the company. The capital stock of the concern, which makes steel balls for machinery, was increased from $500,000 to $1,800,000.

The concern came to Ann Arbor in 1913, being the old defunct Flanders company ball bearing department. It started with floorspace of 29,000 ft. and thirty-two employees and annual sales of $163,000 the first year. Floorspace is now 112,506 sq. ft., there are more than 700 employees and the sales record up to July 31 is $1,310,001. Dividends to the amount of $264,975 cash, and stock dividends of $150,770 have been made to-date, and according to the company's report every stockholder has received back his original investment in dividends.

The company has on its books now, orders for 400,000,000 ¼-in. basis balls which are as yet unfilled.

Security Prices Advance

General Motors, Chevrolet and United Motors Rise on Good Market

NEW YORK CITY, Oct. 18—Despite bearish activities, automobile and accessory issues last week held strong, and holders of these issues on margin netted large gains on a number of the stocks. General Motors on the Stock Exchange and United Motors on the Curb featured the week's activities with gains of 40 and 5 points, respectively. Although trading in such an expensive issue as General Motors is necessarily restricted, the behavior of that stock in the last few days seems to indicate that stockholders are inclined to look favorably on the new reorganization plan presented by the directors. On Monday the stock opened at 760 and closed at 779½, and yesterday there was a further advance to 790, the highest price the stock has ever touched; in fact, the highest price any stock listed on the Stock Exchange has ever reached in the regular way of trading.

United Motors has been subjected to much short-selling. Speculators believed that it would decline on account of the submarine scare, but the stock has steadily risen on account of heavy outside buying and as a result those holding the stock on margin were treated to a gain of $5 a share for the week. Rumors state that this stock is slated to go much above 100 before Christmas.

Several of the tire issues were strong and higher. Firestone continued on its skyward movement and reached 1125, a gain of 5 points; Fisk common rose 5 points; Miller Rubber rose 5 points; and the rest of the issues rose fractionally.

Activities on the Detroit Exchange, on the other hand, were mainly subject to short selling. Prices were lower. General Motors dropped 10 points; Maxwell declined 8 points; Studebaker dropped 6½ points; other losses ranged from a fraction to 5 points.

—

Kelly Truck Capital $7,000,000

COLUMBUS, OHIO, Oct. 13—The Kelly-Springfield Motor Truck Co., has filed papers with the Secretary of State increasing its stock from $1,740,000 to $7,000,000. The shareholders have ratified the increase. The shares will be divided as follows: Common, $2,000,000, against $900,000, formerly; preferred, $5,000,000, compared with $840,000.

—

Republic Rubber Enlarges

YOUNGSTOWN, OHIO, Oct. 14—The Republic Rubber Co., this city, has offered 10,475 shares of its common stock pro rata, at par, to its common stockholders. The proceeds, about $1,000,000, will be used for working capital and extensions.

The members of the executive committee of the board of directors have asked the stockholders to waive their rights to subscribe to an additional 5000 shares of common stock. It is understood that this block of stock will be held for dis-

Canadian Ford Co. Earns 15.8 Per Cent

DETROIT, MICH., Oct. 13—The net earnings of the Ford Motor Co. of Canada, Ltd., for the fiscal year of 10 months ending July 31, after deduction of $716,136 for special war taxes, were $1,109,322.14. The net earnings are equivalent to 15.8 per cent on the outstanding $7,000,000 of the company's authorized $10,000,000 of capital stock.

The net earnings for the latest year prior to the war tax deductions were $3,202,000 for a full year of 12 months ending in 1915.

Difficulties in obtaining vessels for export business reduced earnings.

Cadillac Breaks Record Across Iowa

DES MOINES, Ia., Oct. 14.—H. R. Wells of Des Moines drove a Cadillac eight across Iowa over the River-to-River Road on Oct. 11 in 7 hours and 49 min. The total distance covered was 331.2 miles and the miles per hour elapsed time was 42.37. This new record is 50 min. better than the previous mark made in September by W. J. Barndollar in a Packard twin-six over the same route in 8 hr. and 39 min. The same route was used also by Mulford in his recent runs across Iowa. Wells drove a touring car with top and windshield up and carried three passengers. He left Davenport at 6:37 a. m. and was checked in at Council Bluffs at 2:26 p. m. The last 142 miles of the run was covered at the rate of 44 m. p. h. Wells set a cross-Iowa record of 9 hr. and 14 min. 3 years ago and this stood until the Barndollar record of last month which was over a shorter mileage than that covered by Wells in his old record.

—

Myle-Mayker Gives 26.6 M.P.G. on Ford in A. A. A. Test

CHICAGO, ILL., Oct. 16—In a test held under the supervision of the American Automobile Assn. a Ford car was driven 26.6 m.p.g. after being equipped with a Myle-Mayker, produced by the Myle-Mayker Co., this city. The car, weighing 2267 lb., with four passengers and the top and windshield up, first made 22.5 m.p.g. without the Myle-Mayker. The addition of the Myle-Mayker, which was attached to the standard carbureter in about 1½ min., increased the mileage to 26.6. Acceleration tests without the device gave an increase from 7.5 m.p.h. to 30 m.p.h. in 24 sec. With the Myle-Mayker the same increase was made in 22 sec.

Allen Adds Two Closed Models

FOSTORIA, OHIO, Oct. 16—The Allen Motor Co. has added two closed models to its line. These are a coupé, at $1,075,

Brown-Lipe-Chapin Co. Sold to United Motors

(*Continued from page* 641)

wealthy Syracuse capitalists connected with the Smith-Premier typewriter company. The connection of these gentlemen with Brown-Lipe-Chapin has been that they have owned approximately one-half of the stock, the remainder being held by C. W. Mott and his General Motors associates.

This latest purchase gives the United Motors Corp. a strong array of seven large progressive manufacturing organizations, each of which is continued as separate manufacturing concerns. The list to date includes: Hyatt, New Departure, Delco, Remy, Perlman, Klaxon and Brown-Lipe-Chapin. Some conception of the magnitude of these different concerns may be had from detailed figures on each.

The Dayton Engineering Laboratories occupies seven buildings and has 11 acres of floor space. Last year it produced 142,500 Delco installations and aims at 250,000 for next year. On July 15, 500,000 Delco installations were in use.

The Hyatt Roller Bearing Co. occupies twenty-one buildings with a total of 900,000 sq. ft. floor area. It employs 5000 persons and has a daily capacity of 40,000 roller bearings. Over 7,500,000 Hyatt bearings were furnished to the automobile industry in 1916 and it is estimated that 10,000,000 will be furnished for 1917.

The New Departure Mfg. Co. is manufacturing 21,000 bearings per day and by July 1 hopes to have capacity for 30,000 to 35,000 per day. The company is at present operating two factories, the major one at Bristol, Conn., and one for small bearings at Hartford, Conn. Its factory capacity will be doubled by July 1.

The Remy Electric Co. has a plant of twent-nine buildings with a floor area of 169,000 sq. ft. or equivalent to 4¾ acres. The present output is 950 ignition systems per day to which must be added 400 generators and 350 starting motors. This year's production will total 410,000 ignition systems and 125,000 starting and lighting systems.

The Perlman Rim Corp., a recent incorporation, followed the court decision on the Perlman rim patent rendered some months ago. The company secured the plant of the Jackson Rim Co., the capacity of which is being doubled, to give a total floor area of 129,400 ft. Some months ago the factory capacity was 2000 sets of rims or 10,000 individual rims per day. This capacity is being increased by new buildings which are now in course of construction.

The Brown-Lipe-Chapin Co., making differentials entirely, employs upward of 2000 workmen, and is the largest differential making concern in the world.

Lovell-McConnell Mfg. Co., manufacturer of Klaxon horns, was purchased in September, and plans made to double the production schedule.

and a convertible five-passenger sedan at $1,095. The sedan is a convertible type in which the roof is permanent and the windows and door fillers can be removed and put out of sight in a compartment back of the rear seat. Both cars are mounted on the standard Allen chassis.

Five Moon Closed Models

ST. LOUIS, MO., Oct. 12—The Moon Motor Car Co., this city, will build five closed body models which will be ready for delivery in November, as follows:

Model 6-43—touring with demountable top, $1,450.
Model 6-43—cabriolet, seats three people abreast and one on drop seat, $1,850.
Model 6-66—cabriolet, seats three people abreast and one on drop seat, $2,150.
Model 6-66—coupe, seats three people abreast and one on drop seat, $2,150.
Model 6-66—sedan, with sloping windshield, single door at each side, and seven-passenger capacity, of Springfield metal body type, $2,250.

—

Firestone Holds Sales Convention

AKRON, OHIO, Oct. 15—The Firestone Tire & Rubber Co., this city, is holding its annual sales convention this week, starting Oct. 17 and continuing for 3 days. About 500 salesmen and agents of the company will be in attendance.

Packard Opens Used Truck Department

NEW YORK CITY, Oct. 18—The Packard Motor Car Co. of New York, has opened a used motor truck department at 239-241 West Fifty-sixth Street.

New G. E. Rectifier at Show

—

Small A.C. Device at Electrical Exposition Uses Argon —Other Exhibits

NEW YORK CITY, Oct. 14.—Several new things of interest to automobilists are exhibited at the Electrical Show at Grand Central Palace. One is a new small-capacity alternating current rectifier shown by the General Electric Co. An entirely new principle is used, the gas in the bulb being argon instead of mercury vapor. It has several advantages over the mercury arc rectifier. It is inherently self-starting; 25 per cent cheaper to build and operate; slightly more efficient; more compact; requires less auxiliary apparatus, and most important of all, it can be made in very small sizes, for charging even a single storage battery. At present it is made in two capacitles, 2 and 6 amps. The smaller delivers 1 amp. at 15 volts or 2 amps. at 7.5 volts. The price is $14. The larger is 75 volts and will charge up to thirty cells or ten three-cell batteries. It is equipped with an ammeter and sells for about $100.

Detroit Electric Lowers Price

The price of the Detroit electric has been reduced to $1,775, and a four-passenger body fitted, seating three on the rear seat. In all essential details the machine is the same as its predecessor. It has a forty-two-cell battery, wheelbase is 100 in., tires are 34 by 4½. Standard color is cobalt blue with wire wheels in white, cream, red or blue, as desired by the purchaser.

New 6-Ton G. V. Truck

A 6-ton heavy-duty truck is a new model shown by the General Vehicle Co., L. I. City, N. Y. It has a particularly convenient demountable battery cradle which is so designed that it may be removed either by dropping into place or sliding out to one side. Its speed is 6 m. p. h. and it will operate about 30 miles on a charge, having a forty-four-cell G. V. X. battery. Price is about $5,300 with body. An interesting feature of the body shown, which was for delivering coal, was the use of a Wood hydraulic hoist, driven by an electric motor, permitting the driver to raise the body and discharge its load without leaving the seat.

Hupp Tour Reaches Far West

DETROIT, MICH., Oct. 16—The United America Hupmobile is nearing Seattle after traveling over snow-covered mountains on the trail between Billings, Mont. and encountering several heavy storms. After reaching Seattle the tourists will turn southward and travel as far as Los Angeles.

N. Y. S. A. E. To Discuss Aluminum

(*Continued from page* 643)

universal employment of aluminum.

Concerning aviation motors, the employment of aluminum is carried to the limit. A word or two is devoted to the comparison of the aluminum with the pressed steel construction being tried out on a few experimental motors. Mention is made of the trend toward having the crankshaft lie well within the case, that is, with the crankshaft center line well above the plane of the bottom of the case. The advantages of the cast aluminum band over the steel stamping are mentioned.

The next matter considered is the use of aluminum in the rear axle. Prophecy is made that a great deal more attention is going to be devoted to this question of the reduction of unsprung weight within the next 2 or 3 years than ever before.

The balance, and by far the greater part of the paper is devoted to the employment of aluminum for cylinder construction. The matter is considered historically at the outset. It is pointed out that apparently Europe has stolen the march on this country in the actual production in quantity of aluminum motors, the Hispano-Suiza motor being cited.

A paragraph or so is devoted to answering various questions that have in the past been asked regarding the differences in behavior between an aluminum and a cast-iron motor. The discussion of types of motor is then taken up. Practically every conceivable type of motor has been made, poppet valve, rotary valve and sleeve.

Pistons come in for some attention. That the aluminum piston is the ultimate is very strongly emphasized. Troubles which developed with them are characterized as growing pains. The tendency to carry weight saving to the limit in the aluminum alloy piston is deplored and a saving of 100 per cent should be well worth while. The advisability of the employment of a long piston is receiving attention. The rule is laid down that the length should be equal to 1 1/3 the piston diameter proportions which were advocated in a paper given by the author last November before the society. The motor should be built around the piston and the employment of aluminum pistons should not be an afterthought.

Some little space is devoted to the employment of cast aluminum panels in motor car body construction. The advantages that this type of construction possess are touched upon.

The minor aluminum castings used about a motor car are given some consideration, more particularly the aluminum brake shoe is discussed. A paragraph or so is devoted to the comparative machining of aluminum and cast iron together with some allusion to relative costs. The paper is concluded with a few do's and don'ts that the engineer should bear in mind when designing an aluminum structure. Great stress is laid on the wisdom, in fact, necessity that the engineer should at all times be in very close touch with the foundry when designing structures of this sort.

In the concluding paragraph the fact that the output of aluminum is from 283 lb. in 1886 to 136,400,000 lb. in 1914 is mentioned and an analogy is drawn between that and the development of iron. The paper is accompanied by eighty lantern slides emphasizing some of the points brought out in the paper as well as showing some of the typical castings being produced to-day.

Taxicab Design

SOME years ago there was a prevalent idea that the manufacture of taxicabs was going to be a profitable undertaking, but experience soon showed that this was not the case in a general way. At present there is an immense demand for good cabs, and practically no supply worth talking about.

The taxicab stands half way between the private car and the truck. It must be capable of being handled roughly, yet it has not any great loads to carry. It must have an engine that will be economical of fuel and the chassis and body must be light enough to permit a good tire mileage without being so light that they will give way under the bumps and bangs of taxi chauffering.

More than one taxicab company has tried many sorts of standard touring chassis, and found weaknesses in them all, with the result that it is not uncommon to find these concerns now building their own cabs, using some stock parts and some special ones.

In Europe, much the same state of affairs prevails. The most successful taxicab company in the world is in London. Originally it equipped with French and British chassis costing about $2,000 each, and built special bodies for them. Then, as weakness developed, the repair department was enlarged into a factory, and new parts made to new design, the resulting vehicle being a compromise between the British and French originals with new engineering added.

A taxicab cannot be built cheaply if it is to remain in use for year after year. The service calls for the best workmanship and the best materials, but there should be room in the American industry for a taxicab specialist manufacturer who is not afraid to ask $2,500 for his cab, or even more.

More Standards

THE session of the S. A. E. standards committee, held at the Bureau of Standards, in Washington, on Oct. 18, is not, in many ways, the most important yet, because, for one thing, the number of new proposals to be passed upon is not great. Still, the place of meeting will mark the occasion in the annals of the society.

Engineering standardization began as a thing altogether separate and apart from National standardization. There is a fundamental difference between the standard of money and the S. A. E. carbureter flange standard, for example. However, some engineering standards are national, like the U. S. screw thread, and more will be in the future.

Standards which are law, and hold for all time, are one thing; standards which are custom by agreement, and may have to be changed from time to time, are different; but there is no sharp dividing line. The enormous amount of work done in the past 10 years by engineering societies is obtaining recognition by the governments of the world; governments and the engineering industry are helping each other more than ever before.

Of the total of work done by societies, that belonging exclusively to the S. A. E. stands very high, and lately the S. A. E. and the Bureau have had to consider common subjects simultaneously, and it is probable that the relationship will be much closer in the near future.

The Spotlight

THE use of a spotlight has for many years been forbidden absolutely by the law of Great Britain, because of the power for annoying other road users that it gave a driver. There are signs that similar prohibition may be adopted by several of the States in the Union for the same reason.

The situation is regrettable. The spotlight is really very useful. For reading a sign, for examining a turn in the road, or for driving on a very bad and dangerous highway, where a strong light on the edge of the road is necessary, the spotlight is ideal. If it were only used in this way, in the way its originators intended it to be used, we should hear no complaints; but as things are, the avoidance of a difficult situation appears almost impossible.

The abuse of the spotlight is complicating the glare problem to quite a perceptible extent; it is making the work of those who are really solving the glare matter harder than it needs be. What a pity it is that the abuse of a good thing by a minority of fools should place its existence in jeopardy!

Resta Wins 250-Mile Grand American

Averages 103.99 M.P.H.—Aitken 6.93 Sec. Behind

Aitken, DePalma, Resta and Hughes in a brush early in the race

Prize Winners in the Grand American Race on the Chicago Speedway

Car	Driver	M.P.H.	Prize
Peugeot	Resta	103.99	$6,000
Peugeot	Aitken	103.65	3,000
Maxwell	Rick'bacher	102.08	1,500
Premier	Lewis	98.37	1,000
Maxwell	Henderson	98.34	900
Premier	Galvin	97.81	800
D'senberg	Devore	90.58	600
Ogren	Burt	86.66	500
Erbes	Gable	81.13	400
Hudson	Vail	80.81	300

CHICAGO MOTOR SPEEDWAY, Oct. 14—By the narrow margin of 6.93 sec. Dario Resta continued his unprecedented record of winning every big event on the Chicago Speedway to date. In to-day's 250-mile Grand American race he finished victor with this slender lead over John Aitken, thereby getting back first place in the ranking for the speedway championship of the season. Winning to-day's race, the closest ever witnessed on this speedway, gives Resta 3200 points, while Aitken, who was in the lead up to this afternoon, is now second with 2940. Resta broke his own record of 97.70 m.p.h. for 250 miles on this track.

The race resulted in a three-cornered battle for supremacy between Resta, Aitken and Rickenbacher, who finished third. Resta made but one stop at the pits, changing a right rear tire and taking on gasoline at the 190th mile in 28 sec. This was neither as thrilling nor as costly as Aitken's only pit visit, which occurred shortly after. With a lead of only half a lap over Resta, Aitken blew a right rear and, fearing delay, headed for the pits at terrific speed. Opposite the judges' stand his car started to skid and rocked from side to side till it slid sideways up the track a distance of 100 ft. past the pit, turning completely around. Aitken threw in low gear and shot up to his pit from the wrong direction. Despite the excitement his pit crew changed the tire with the car facing the wrong way and sent him away in 30 sec. But Resta had taken advantage of his opportunity and was well in the lead, a lead which Aitken could not overcome for long though he forged to the front for a brief interval later in the race, the cars running wheel-to-wheel for the last 50 miles.

Rickenbacher's Maxwell was third, 1 min., 29.15 sec. behind Aitken, although his car was not running very well at the start of the race. Lewis, in a Premier, was fourth, with Henderson's Maxwell, Galvin's Premier, Devore's Duesenberg, Burt's Ogren, Gable's Erbes and Vail's Hudson following him across the tape in the order named. Rawlings in the West Duluth was flagged, covering almost the entire distance on three cylinders. Buzane was also flagged.

All track records were smashed up to the end of the first 40 miles by DePalma, who averaged 105 m.p.h.

The race was between the four favorites, Aitken, Resta, DePalma and Rickenbacher, and DePalma led for 120 miles

The Big Four of the race, Rickenbacher, Resta, DePalma and Aitken

Photo by International Film Service
As the race drew near its close, Resta led with Aitken second and Vail third

in one of the most closely fought contests ever seen on an American speedway until he lost first place to Aitken on account of a tire change and then dropped back to third through two stops caused by a broken valve which was the ultimate cause of his withdrawal.

One Serious Accident

One accident marked the day's event and one which may cause the death of Ralph Hetlich, mechanic for Wilfred D'Alene, driving the Crawford. D'Alene came into the pits at the end of his 15th mile for gasoline and the excited pit man spilled gallons of gasoline onto the track under the car and finally some of it, when the funnel was knocked off, was ignited by the exhaust. The car and the gasoline below it burst into flames which rose to 10 ft. in the air. Hetlich's clothing was splattered with burning gasoline and, temporarily crazed by the pain, he ran up the track toward the judges' stand. Here he was headed off by some of the officials who forced him into the dirt under the judges' stand and wrapped coats about him until the burning clothing could be torn off. He was rushed to the hospital and hope for his recovery is held out, although he is very seriously burned.

Billy Chandler, captain of the Crawford team, also was burned about the hands and throat and the back of the head. It was necessary to force him into the ambulance as, in spite of his injuries, he insisted on endeavoring to help Hetlich.

The fire about the Crawford car was put out in 3 min. by the rapid and efficient work of the J-M fire extinguisher crew which, in spite of the fact that it had to run the entire length of the pits to reach the burning car, subdued the flames before great damage had been done to it.

While the car was still hot and smoking from its inundation in flame, D'Alene again took the wheel with a substitute mechanic and resumed the race. He circled the track once but was forced to come in with the brake bands still burning to change one of the rear wheels whose tire had been damaged by fire; also, to make another attempt to fill the gasoline tank. D'Alene was able to make only four laps more before the scorched car was pushed down the track with a broken driveshaft.

DePalma Takes Lead

The actual start after the preliminary lap was a very pretty one, the line being well kept for the getaway. Aitken led at the end of the second lap but DePalma took the lead at the third lap, having passed Hughes, Resta, Henderson, Wilcox and Aitken in a 2-mile spurt that brought the grandstand spectators to their feet. The order at this time was DePalma, Resta, Aitken and Hughes, with a gap beginning to open up between these four leaders and the rest of the field, all of whom were leaving Gable and Buzane some distance in the rear. At the end of the first 10 miles Gable, whose car was missing badly, was lapped in front of the grandstand. Wilcox and Henderson had crawled up until they were respectively second and third to DePalma, with Aitken, Hugher, Resta and Rickenbacher following in order.

D'Alene again began to show among the leaders and at the end of 14 miles was well up to the front. The speed was too fast for him and he did not maintain his position long. Before 20 miles were gone the speed began to tell on some of the cars and they began to come into the pits, Burt's Ogren being docked temporarily first, and followed shortly by Buzane in the Duesenberg and Vail's Hudson.

The pace was a terrific one, DePalma's time for first 20 miles being 11 min. 34 sec., with Resta, Hughes, Aitken, and Rickenbacher all close at his heels. Resta's time was only 2 seconds slower than DePalma's, while Aitken was running half a length behind. Rickenbacher, D'Alene, Hughes and Burt were all very close up.

During the next 10 miles Aitken and Rickenbacher passed Hughes and the order then was DePalma, Resta, Aitken and Rickenbacher. DePalma was being sorely pushed, the three Peugeots running so close together that there was not a car length between DePalma and Aitken. Rickenbacher was 100 yd. behind. All were traveling at better than 103 miles per hour. Hughes went out with a broken valve spring in the 32nd mile. It was this that caused him to lose his position during the few miles previous. Hughes asked of the car more than it would stand, and while he made a wonderful showing for the first 25 miles the mechanism would not stand the speed he called from it.

A Four-Cornered Race

For the next 70 miles the four-cornered race between the leaders continued, with the speed slowly increasing, and lapping car after car as the three blue Peugeots and the white Maxwell fought for the lead. But DePalma was never headed in the first century. At 40 miles the time was 23:3.65, a speed of 105 miles per hour. At 50 miles it was 29:50 sec., approximately the same speed.

After the accident to D'Alene's car the speed dropped somewhat for a time but again picked up. At 70 and 80 miles the speed had dropped to 102 miles per hour. Rickenbacher was the first of the quartette to show the effect of the terrific speed, having to come into the pits at about 76 miles for a right rear tire. His pit work was very fast and his time lost slight, not enough to cause him to lose his fourth position. At 80 miles the order of the first ten was as follows: DePalma, Resta, Aitken, Rickenbacher, Wilcox, Devore, Milton, Henderson, Klein and Lewis. DePalma's time for this distance was 45:25, a speed of little better than 102 m. p. h. At 90 miles the order was practically the same throughout, and the speed increased slightly to 102.5 miles per hour. DePalma was still leading at the 100-mile point and his time was 56:58.41, a speed of 105.2 m. p. h. DePalma came in shortly after this, making his first stop and changing a right rear tire. This caused him to drop back into third place, as Resta and Aitken both passed him.

Rickenbacher was improving his opportunity to make up time lost by his stop and still further increased his speed,

when he saw DePalma at the pit, making laps at 106 m. p. h. as he forced his car to its utmost.

Resta Sets the Pace

With DePalma temporarily out of the lead, Resta set the pace with Aitken close at his heels, so that at the 120-mile mark Resta was leading, Aitken second and DePalma third, with Rickenbacher a bad fourth. The time at this point was 1:08.22, a speed of 105 m. p. h.

The terrific pace brought Resta in to the pits on the next lap for supplies, taking on gas and changing a right rear tire. The pit work was very fast, Resta being held only 28 sec.

Aitken had not stopped as yet and the two halts by the leaders put him in the front. This he held for the next 70 miles. Resta's stop let DePalma overtake him so that the Italian was pushing Aitken for first with Resta and Rickenbacher following. From the 140-mile point until after approximately 190 miles had been covered he came in with his engine missing badly, and after a lap or two withdrew with a broken valve.

Aitken's Narrow Escape

Almost at the same time Aitken very nearly ended his chances for finishing the race when, in coming in with a flat tire for his first stop at the pits, he skidded badly, turning completely around, but by masterly handling kept the car on its four wheels and pulled up at the pits, facing in directly the wrong direction. He was away in 30 sec., but meanwhile Resta had passed him, taking the lead. The old National driver gave the car all it would take when he took up the chase of the Italian and turned several laps in 1:05, a speed of better than 109 m. p. h. At 200 miles Resta was leading, Aitken second, Rickenbacher third, and Wilcox fourth. Resta made the distance in 2:07.01, with Aitken only 2 sec. behind. Rickenbacher was a minute behind the leader and Wilcox was over 2 min. behind having been lapped by Resta and Aitken. Their speed at this point was close to 105 m. p. h.

Resta and Aitken ran neck-and-neck for the 50 miles remaining but Resta was always a nose ahead of the Indianapolis driver, except for one short space, when Aitken succeeded in crowding ahead temporarily. Resta undeniably could have made more speed at this time had it been necessary for him to call upon his car for it.

Slipping Clutches Give Trouble

THE race developed a new ailment. Slipping clutches have seldom held such an important part in speedway races. Ostewig, in the car bearing his name, was in the pits four times, consuming in the neighborhood of 20 min., dosing his clutch with dirt, sand, and finally inserting hack-saw blades to lock it in place. Milton went out entirely with a shredded-clutch facing and it was the claim that Johnny Aitken's speed was reduced throughout the contest by a clutch that persisted in increasing the ratio between the engine and the rear wheels.

There were thirty-nine stops in all, and only eleven of these were for tires. The other twenty-eight went to patch up mechanical difficulties.

As a matter of habit, Resta's one pit stop was made in record time for the meet. He changed a right rear and took on gasoline in 28 sec. This however was a plain slide-in-and-roll-out-again stop, and not as costly or exciting as Aitken's only pit visit, already described, the Hoosier pilot nearly coming to grief as he tried to shoot into his pit at high speed for a new tire. This stop cost him first place.

The Crawford pit, with one of its cars bearing No. 13, suffered about as disheartening a climax as ever occurred in a Speedway race. After D'Alene took his fire-blackened car back into the race with a new mechanic substituted for the one who was nearly cremated and drove a few more laps a connecting-rod let loose and he was out for good.

On the same lap, Klein's Crawford split a crankshaft and the havoc it wrought in the motor is probably beyond repair. The whole crankcase assembly was literally torn to fragments.

The fire in Devore's Duesenberg can also be attributed to carelessness. He stopped for a tire and the motor did too. The mechanic tried to crank the motor again, and as it would not start he opened the hood and attempted to tickle the carbureter. Instead, he knocked off the cap of the float chamber, the float shot out and the explosive fluid poured itself generously over the car and track. When the motor was cranked, the gasoline-loaded cylinders backfired through the carbureter and started the fireworks. Fortunately it all took place directly in front of the J-M extinguisher pit and these overworked fire-fighters made quick work of it.

Ralph DePalma went out with a broken valve. This Peugeot has been a particular offender in valve trouble, Mulford having run up against the same thing when he drove the car. It is getting to be a conventional statement that Ralph goes out with some part of his motor broken and many race fans have ventured to ask "Where is the DePalma of a year ago?" The veteran driver once carried the reputation of humoring his car in the early part of a race and leaving his spurt for the last. His tactics throughout the 1916 season have been just the reverse, and there does not seem to be a car built that will stand his Burman-like driving.

Other Mechanical Troubles

Again Buzane's Duesenberg sprung a leak in the water pump. This car has this particular trouble as regularly as the starting flag is waved. In to-day's race it was even worse than ever and the water which spurted from the leaky pump packing found its way into the carbureter and caused four pit stops.

Wilcox, another of the Peugeotic contenders, experienced a typical DePalma last hour demise when he rolled into the pits with one lap to go with a broken rod. He was then running in fourth place which made the faulty connecting-rod an expensive investment.

Ira Vail, who drove his battery-ignited, starter-equipped

Value of Rating Formula Limited

Can Never Involve Any but Qualities Capable of Mathematical Measurement—May Be Useful to Engineers and a Few Car Buyers—Detroit S. A. E. Discusses Fishleigh's* Paper

By J. Edward Schipper

DETROIT, MICH., Oct. 14—The Detroit section of the S. A. E. is agreed that it is impossible to measure all that is meant by the term "Car Performance" in a single formula. This is perhaps not a new idea, but it was certainly crystalized in the discussion following the reading of Professor Walter T. Fishleigh's paper on Automobile Performance and Methods of Comparison at the monthly meeting of the section last night.

Everyone present agreed that it is possible to get a formula that will act as a very satisfactory basis of comparison. The mathematical factors of comparison—speed range, accelerative ability and fuel economy—are basic and can be so treated, but all other things, such as comfort, either mental or physical, ease of control, etc., cannot be embraced by a mathematical expression.

Eliminating the important comfort factor of course removes a large part of the value of a rating factor as far as the average individual that buys a car is concerned, but it in no wise affects a great many points of value which such a formula may have for the engineer or even a car-educated buyer who carries his investigations further than what he would secure from a demonstration. The mathematical factors which remained unscathed by the discussion and which would be above criticism in the rating or performance comparison were those of speed range, accelerative ability and fuel economy.

Whether or not these should be all combined into one figure was a matter considerably open to debate, as it was pointed out that by combining them the relative value of each term was forgotten and therefore they should be allowed to stand in their original form so that a man who was buying a car by this rating method would be able to give greatest weight to either speed range, acceleration or economy. The three factors were called in Professor Fishleigh's paper, *S*, *A* and *E* respectively, being also the initials of the Society.

Professor Fishleigh is a member of the standards committee of the S. A. E., and since one of the divisions of the committee to which he is attached has in hand the matter of determining a standard S. A. E. rating formula, the paper and its discussion take on considerable significance. The question seems to have two sides: first, what is the rating formula for; and second, the determination of the formula.

Last night's meeting seemed to settle the first point very satisfactorily, and summed up in a nutshell it may be stated that the rating formula is for the purpose of comparing the combined factors of performance which are capable of mathematical measurement.

The second part of the question was not so clearly solved, as there was no general agreement on all the factors that should be involved in the final result. The latter difficulty, though, is certainly more easily overcome than the first seemed to be, and a number of formulæ that were satisfactory to 500 members in attendance were offered, particularly by C. T. Myers of the Timken Co., C. C. Hinkley, chief engineer of the Chalmers company, and K. W. Zimmerschied, engineer of the General Motors Co.

Automobile Performance and Methods of Comparison

By Walter T. Fishleigh*

IN general, factors which make for good car performance have come to be more or less agreed upon. In general, the tests which show the degree of car performance or car ability are pretty well recognized, and there is little doubt that if a new model were to be handed over to any committee of three selected from this meeting to-night with instructions to try it out for general performance, approximately the following tests or their equivalent would be made.

1. The car would be driven upon good pavement to determine its range of operating speed, that is the lowest and highest speed at which and between which the engine and car operate steadily and successfully.

2. The acceleration would be tried out, probably starting at the lowest steady operating speed and determining the time necessary to accelerate to its maximum speed, or perhaps the test would be run between two arbitrarily set limits, as from 5 to 55 m.p.h.

3. The car would be tried out on steep grades or hills. This test would involve both high gear work at different speeds, and operation in the gears.

4. Tests would be made upon the road or upon a speedway to determine fuel economy; that is, miles per gallon of gasoline. Economy runs have often been made and advertised as under "average touring conditions," but upon consideration it will be manifest that economy runs, to be scientific, definite and comparable, should be run at a number of definite speeds, as for example, 10, 15, 20, 25, 30, 40, 50 m.p.h. The results will give an economy curve, which tells the complete story of economy at various speeds. An average fuel economy may be found from this curve, but the detail curve itself is not only desirable but necessary.

5. The car would be run over good, bad and indifferent roads, at various speeds, and going through various maneuvers, for the determination of riding comfort. This factor is the resultant of many items in design, such as weight, wheel base, spring suspension, engine characteristics, body and seat design, etc. If carried to the theoretical limit, it is an exponential function also of the way an engine pumps

*Professor Automobile Engineering, University of Michigan.

oil and soots the spark plugs, the kind of gear shift employed, the number of punctures per tire per mile, and the percentage rise in small-town hotel prices when the driver pulls up with a particular make of car and applies for accommodations. These latter, though important, may be neglected in the present discussion.

Summing up the above, we may assume that for completely trying out car performance, tests would be run for the determination of (1) range of operating speed, (2) acceleration, (3) hill climbing ability, (4) fuel economy in miles per gallon, (5) riding comfort. It is proposed that acceleration tests be agreed upon as the standard factor in car performance for indicating excess draw-bar pull. Complete performance then becomes the resultant of the following four factors:

1. Speed range
2. Acceleration
3. Economy of fuel
4. Riding comfort

The application of each of these factors needs hardly to be argued; whether there should be more or fewer of them is open to argument.

Expressing our discussion mathematically, we may write:

Automobile performance varies directly as speed range, acceleration, economy of fuel and riding comfort.

$$\text{Automobile performance} \propto S.A.E.C.$$

Where S = speed range in high gear, in miles per hour
A = average acceleration of car in feet per second per second over the complete range of its operating speeds.
E = average fuel economy, over the complete range of its operating speeds, in miles per gallon.
C = riding comfort factor, which must be determined by each individual judge.

It is manifest that complete car performance or car ability, on account of the item C, cannot well be determined once for all by rigid tests, nor estimated in any simple and practical way. The one item C must be left to personal judgment, if not to personal eccentricity. In considering car performance, however, the other items ($S.\ A.\ E.$) are each susceptible of scientific determination and measurement, and their combination when obtained, while not giving the complete expression and answer for car performance, still affords a valuable comparison for cars and constitutes what might well be called the Automobile Performance Factor.

$$\text{Automobile Performance Factor} = S.A.E.$$

When considered from the standpoint of this three-fold "Automobile Performance Factor," different cars can be definitely tested, a definite value for each item in the factor obtained, and relative performance quantitatively rated as regards speed range, acceleration and economy of fuel. For the engineer, the manufacturer and the buying public this factor affords a ready and reliable means of comparison of car performance, and an investigation of the three items, which go to make up the complete factor, leads at once to comparative values in the details of performance. Illustrating the application of this automobile performance factor, suppose we have two cars; the first with speed range 10 to 50 m.p.h., acceleration from 10 to 50 m.p.h. in 30 sec., average miles per gallon 20; the second with speed range 5 to 65 m.p.h., accelerating from 5 to 65 m.p.h. in 20 sec., average miles per gallon 10.

$$\text{Automobile Performance Factor} = S.A.E.$$
$$\text{For first car} = 40 \times 20 \times 2 \quad (=1600)$$
$$\text{For second car} = 60 \times 10 \times 4.4 \ (=2640)$$

The value of this factor, or more properly the value of the three items in the factor, coupled with a consideration of item C (riding comfort), leads to accurate estimate of complete car performance or car ability and should form a sound basis upon which to judge the car as an operating unit. Indeed, we may individually go even further, assign a relative percentage value to the comfort factor C, multiply our car performance factor by it, and obtain at once a figure for each car which represents complete car performance or car ability. Some question may rightly be raised as to the relative weight which should be given each of the items S, A and E in the factor, but after extended consideration, it would seem that from the standpoint of importance to the operator, no better than equal weights can be assigned. In this factor, the item "car weight" does not appear separately, but indirectly exerts its influence upon S, A and E. In each case the penalty for increased weight appears in a reduction of the value of acceleration, mileage per gallon of fuel and speed range, the effect upon the final automobile performance factor being marked. It must be clearly emphasized that the items in the performance factor have reference solely to performance of the car as it stands, as an operating unit. The relative advantages of the seven seats of the touring car as compared with three in the roadster, the riding qualities of the heavy car as compared with the light car, the operation of the twin-six engine, as compared to the four or six or eight of equal horsepower, the advantges of the limousine body as compared to the touring car—all these are matters to be settled in a preliminary consideration or to be included with proper weight in the riding comfort, item C. The factor is of particular value in comparing the relative performance of two cars of generally similar characteristics. Nor is it desirable to compare, from the standpoint of performance, widely different structures such as the pleasure car and the truck, vehicles designed for entirely different service, in which the various items which go to make up car performance have entirely different relative values. Indeed, the performance factor for the commercial truck may be quite different and a subject for separate consideration.

A simple and thoroughly accurate acceleration test has been proposed as follows: The car is brought to its lowest successful operating speed and driven at that speed to the starting line of a measured course, where it is accelerated as rapidly as possible to its maximum speed over this course. Measured intervals are laid off along the course, and at each interval a contact point is located which is operated by a small gate carried under the front axle. At the starting line is located a recording drum, revolved by clock mechanism or by electric motor driven by batteries. Writing its record upon this drum is a small marker, which is electrically operated by a calibrated clock and which registers time elapsed in seconds or half seconds. Another marker is electrically operated by each of the various contact points along the course. Thus is obtained an accurate record of the time for traversing each of the measured intervals along the course. From this data, an accurate determination of accelerations at the different speeds can be had, either by means of curve plotting or by calculation. The final acceleration curve will show accelerations in feet per second per second of the car at each speed of its range.

Fig. 1 shows an acceleration curve from a six-cylinder car, total weight 5280 lb., gear ratio 3 10/13 to 1, size of engine 4½ by 5½ in., wheel diameter 37 in. Fig. 2 shows an acceleration curve from an eight-cylinder car, estimated gross weight 4150 lb., gear ratio 5 1/14 to 1, size of engine 3⅛ by 5⅛ in., wheel diameter 36 in.

Typical curves for fuel economy runs at various speeds are shown in Figs. 3 and 4. The curve in Fig. 3 was obtained from tests upon an eight-cylinder car, 3⅛ by 5⅛-in. bore and stroke, gear ratio 4.5 to 1, tires 36 by 4½ in., estimated gross weight 4150 lb. The curve shown in Fig. 4 was obtained from a four-cylinder car, 3⅝ by 4½-in. bore and stroke, gear ratio 3.58 to 1, tires 30 by 3½ in, estimated gross weight 3000 lb.

Other Ability Formulæ

Many formulæ for automobile performance or car ability have been developed. They differ widely in method of ap-

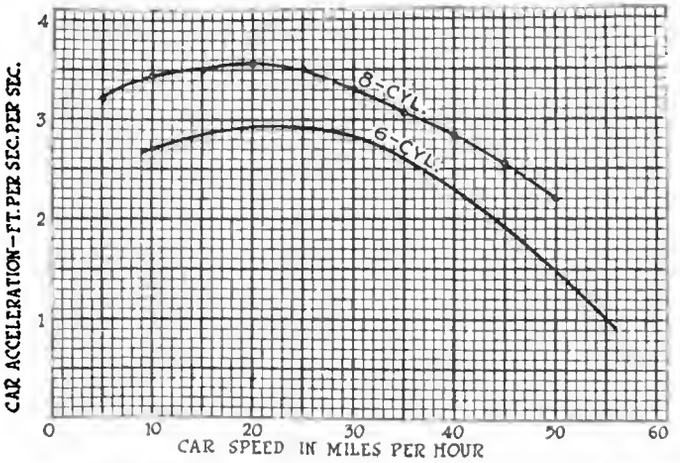

Fig. 1—Acceleration curve for six-cylinder car. Fig. 2—Acceleration curve for eight-cylinder car

proaching the question of performance; they differ in the fundamental factors included; in the majority of cases they are efficiency formulæ strictly, developed for estimating, from engine size, gear ratio, weight, wheel size, etc., what the probable performance or probable performance factors of a car will be; in no cases are they as comprehensive as, in the opinion of the author, they should be to cover the ground of performance; in no case are they based entirely upon accurate, scientific tests which determine at once beyond doubt the true values for the factors which make up performance and, therefore, the true value for performance itself. A consideration of the most important of these formulæ will be of value.

(Symbols used in formulæ):

d = diameter of cylinders in inches
s = stroke in inches
n = number of cylinders
r = gear ratio
D = diameter of wheels in inches
W = gross weight of vehicle in pounds
M = average fuel economy, in miles per gallon
P = horsepower of engine, at a given speed.

1. $\text{Ability} = \dfrac{P r}{W D}$.

This simple formula is one of the oldest and perhaps most widely known for estimating so-called ability. Its mathematical value has a direct physical interpretation, in that at a given speed for cars of equal transmission and rear axle efficiencies, it will be proportional to total draw-bar pull per pound of weight. For cars of different transmission and rear axle efficiencies, the formula becomes more or less inaccurate. Acceleration or hill climbing ability of a certain car at a given speed, however, is proportional to excess draw-bar pull per pound of weight over that necessary to propel the car at the given speed as discussed above, so that even as an estimate of this one factor in automobile performance, this formula is hardly tenable. For two very different cars, such for example as a limousine and a speedster, the total draw-bar pull per pound of weight may be the same, yet the excess drawbar pull per pound of weight (and, therefore acceleration and hill climbing ability) be quite different, especially at comparatively high speeds. The use of this formula as is customary, by the mere substitution of maximum engine brake horsepower for P when two cars are being compared, is of little, if any, value. If maximum torque were used, instead, we should come nearer relative hill climbing and acceleration abilities, but even then the results would not be directly comparable. As a formula for estimating complete automobile performance or ability, it does not include the three factors, speed range, fuel economy and riding comfort. As a formula for use as an automobile performance factor it does not include speed range or fuel economy, and is not strictly correct for acceleration or hill climbing ability.

2. $\text{Vehicle Coefficient} = \dfrac{8 n d^2 s r}{D W}$ —(Myers, 1915).

3. $K = 14550 \dfrac{d^2 s n r}{D W}$ —(Roebuck, 1912).

4. $Q = 3000 \dfrac{d^2 s n r}{D W}$ —(Thomas).

The close similarity of the above three formulæ will be manifest and they may be considered together. Mr. John Younger has pointed out that "these three formulæ represent piston displacement per pound moved 1 ft., and on the reasonable assumption that every cubic inch of piston displacement represents so many foot pounds of energy, these formulæ give a measure of a car's ability. The greater the displacement per pound moved 1 ft., the greater should be the car's ability to speed, to climb and to accelerate on the particular gear reduction considered." From another viewpoint each of these three formulæ represents total drawbar pull per pound of weight. These formulæ like No. 1 may be of value in estimating total draw-bar pull for cars of the same transmission and rear axle efficiencies, providing their engine efficiencies are equal. Considered as formulæ for approximating acceleration or hill climbing ability, practically the same difficulties appear in the use of these formulæ as in the use of No. 1. The constants in these formulæ are the result of a number of assumptions, which in widely different cars do not hold. The constant 8 in formula No. 2, for example, is based upon the assumption that "all motors will develop a torque in pounds at 1 in. radius equivalent to that of their N. A. C. C. horsepower rating," and that the product of engine efficiency by transmission efficiency "for the average well built car will be about 95 per cent." Even aside from these assumptions, these formulæ give us merely an approximate estimate for total draw-bar pull per pound of weight. In no way are speed range, fuel economy or riding comfort taken into account.

5. $\Sigma = \dfrac{1}{10} \dfrac{d^2 s n r M}{D}$ —(Thomas, 1913).

The above so-called "Sigma Formula" differs from the other formulæ considered in that the factor M (average gasoline consumption in miles per gallon) is included. This M is determined by complete tests and is evidently a proper and reliable factor in performance. The remainder of the formula considered alone $\left(\dfrac{d^2 s n r}{D}\right)$ represents piston displacement per foot the entire car is moved, or from another viewpoint it represents total approximate draw-bar pull. In nowise, is acceleration or hill climbing ability proportional to total draw-bar pull, regardless of weight and the draw-bar pull necessary to propel the car at any given speed. The difficulties encountered with this part of this formula are, therefore, as serious as those for formula No. 1, only more so. Only where cars have the same engine, transmission and rear axle efficiencies, will a formula based upon motor dimensions, gear ratio and wheel diameter give a reliable approximation for total draw-bar pull, and this total draw-bar pull is not, in general, a measure of the acceleration or hill climbing abilities of these cars. In this formula, no account is taken of speed range. The curve obtained, however, by plotting values of Sigma for a car at various speeds as shown in Fig. 5, is extremely interesting. This curve was obtained from comprehensive tests upon a six-cylinder car, bore and stroke

5 by 7 in., gear ratio 2.88 to 1, wheel diameter 38 in., estimated total weight 5900 lb.

6. Ability $= \frac{D}{W}$ —(Brush, 1916).

Where D = excess drawbar pull at any speed over that necessary to propel the vehicle at that speed.

This formula, which may be interpreted as representing excess draw-bar pull per pound of weight, gives an accurate measure of hill-climbing ability, an approximate measure of acceleration. It has been proposed that this excess draw-bar pull D at any speed be determined directly by test upon a level course or speedway by attaching a special dynamometer car or attachment to the rear of the car under test and by means of brakes on the special car, control the speeds. If such special car and dynamometer can be devised, and if the dynamometer under the conditions of high speed incident to such tests were to give substantially steady readings which could be relied upon, this method would be direct and acceptable for the determination of that one item, excess draw-bar pull, which in automobile performance is evidenced by hill-climbing ability or acceleration or both. As a complete automobile performance or ability factor, this formula takes no account of fuel economy or of speed range. It is suggested that this $\frac{D}{W}$ value be multiplied by E and then by S, for the complete factor. On the assumption that the proposed tests for $\frac{D}{W}$ values can be successfully carried out, the proposed factor would seem to be satisfactory.

Discussion Full of Suggestions

C. T. Myers, engineer of the Timken company, presided and opened the discussion. He said that Prof. Fishleigh's factor C (comfort) is not susceptible to accurate determination, although the other factors are and the author has accurately analyzed them. There is no attempt to measure the efficiency, but only to indicate it: "A point which will surely be argued," Mr. Myers said, "is the speed range. Another way of looking at this is to use it in a way that will accentuate its effect on the formula by taking the ratio of the highest speed to the lowest. That is instead of subtracting the lower from the highest speed, the highest speed may be divided by the lower."

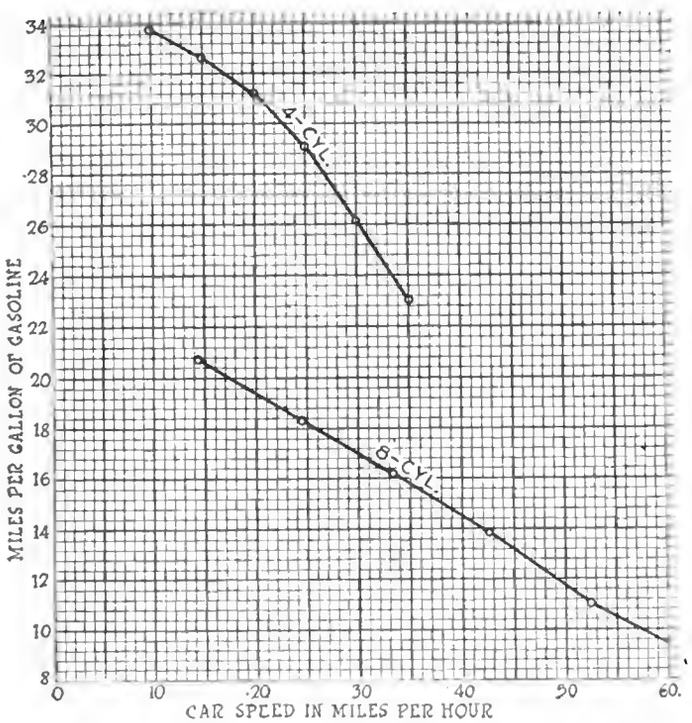

Fig. 3—Fuel economy curve for eight-cylinder car. Fig. 4—Fuel economy curve for four-cylinder car

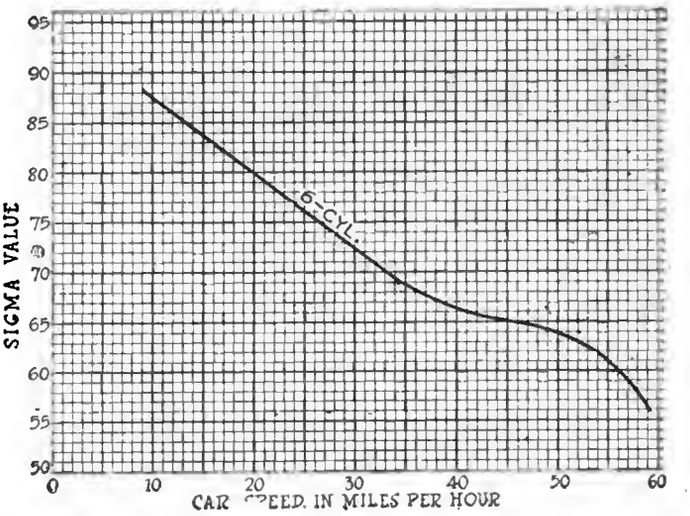

Fig. 5—Sigma values for six-cylinder car sigma formula is $\Sigma = \frac{d^2 s n r M}{10 D}$ in which M is average fuel economy and the remainder of the formula represents displacement per foot of travel

K. W. Zimmerschied, metallurgist of the General Motors Corp., stated that he did not see the necessity for carrying out the multiplication of the factors, as the product does not tell anything. In other words, a man may have an entirely different car and get a product of 2520 in one case and 2500 in another. This is only a small difference in the products, while the cars may be widely different. The real purpose is simply to enumerate the qualities and therefore the product is of no use.

A. P. Brush, consulting motor engineer, said that owing to the efforts of the standards committee to determine a formula, it is necessary that great care be taken in the recommendations. He stated that there are a great many objections to the expression as it stands, i.e., $F = S.A.E.$ "Take miles per gallon," he said. "Is it a factor of performance? It is rather an item in the cost of performance and should be figured with such things as first cost of the car, tire cost and general maintenance expense. Let us also take the speed range factor. According to this method of rating a car that has a range of from 44 to 100 miles an hour on high gear, will be just as satisfactory as one that has a range of from 4 to 60 miles an hour. The object of the high speed engine is to give the user the benefit of low speed performance, and this is important to the average user most of the time.

"The $\frac{D}{W}$ (D is excess draw-bar pull at each speer, W, weight) formula is worthy of consideration, as this makes possible the consideration of the speed range as well as the economy.

"Another point that should be settled is what is meant by the lower end of the speed range. You must call the lower end of the speed range that at which the engine will perform smoothly at wide open throttle. The $\frac{D}{W}$ formula is a direct expression of the sine value of the hill that the car can climb."

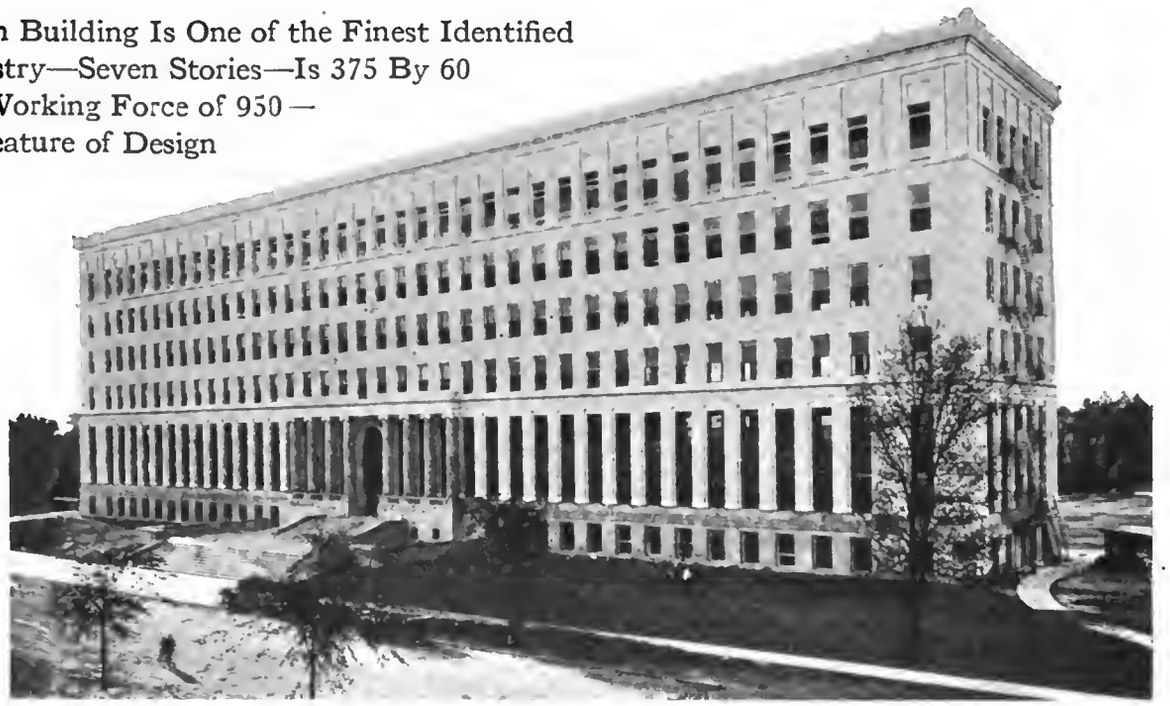
Willys-Overland's New Headquarters

Administration Building Is One of the Finest Identified with the Industry—Seven Stories—Is 375 By 60 Ft.—Houses Working Force of 950—Economy a Feature of Design



Front of the new administration building just occupied by the Willys-Overland Co., Toledo, Ohio. The building is of steel construction with an equitable brick exterior. There are four passenger elevators and one for freight

TOLEDO, OHIO, Oct. 14—The Willys-Overland Co. has just located in its new administration building, which is one of the finest office buildings connected with the automobile industry. It is a seven-story, brick structure, 375 by 60 ft. and houses a working force of 950 people. All of the administrative offices in connection with the factory are located in the building, which is an architectural model to the industry and well adapted for the work. On entering the building the atmosphere is more that of a huge hotel than an executive building for an automobile concern. On the ground floor is a reception room 100 by 30 ft. resembling the corridor of a large hotel. It is filled with large couches, divans, chairs, etc., and fronting on one side of it are the elevators. The building is served by a system of four Otis passenger elevators, each with a capacity of twenty people, in addition to which is a 5000-lb. freight elevator.

The building is of steel construction with an equitable brick exterior giving a most attractive appearance. It is located directly across the factory from the old offices and fronts on the city boulevard and faces what is known as the Model 75 building, that is, the huge assembly building, 1000 ft. in length, in which the Model 75 is built.

The general layout of the administration building has been worked out with economy in every feature as a foremost requisite. Those departments such as Purchasing, Service, and Traffic are on the main floor, so that the elevator service will not be called upon to serve those departments. These are the departments that have most business visits from outsiders per day.

The second floor is given over entirely to accounting and a novelty is the use of steel furniture throughout. Each clerk sits at a steel table and back of it is a steel cabinet, little higher than the table, in which all of the books, etc., are kept.

The third floor may be described as the middle floor of the building; there are three below it, counting the basement, which is a level ground floor, and three above it. On this middle or central floor are all the central correspondence files for the entire building; the force of forty or more stenographers occupies a department of this floor;

Automobile Conditions in Europe

Importations to British Isles and Italy Forbidden—70% Duty Into France—Tires Scarce in Neutral Countries—Better U. S. A. Service Needed on Electric Starters and Generators—More Attention Needed in Export Trade

By Peter Steenstrup

¶Editor's Note:—Peter Steenstrup, representative of the Hupp Motor Car Co. in Europe and Latin-America, has recently returned from a 5-months trip through ten countries in Europe, visiting most of the continent excepting Russia, the Central Powers and Holland. In this article Mr. Steenstrup tells of automobile conditions as he found them.

NEW YORK CITY, Oct. 13—With all the countries in Europe which are not at war, business is generally in excellent shape, and several neutral countries are literally rolling in wealth. With this condition it is not surprising that there is an unprecedented demand for automobiles, and accessories. In filling this demand the U. S. A. is the greatest possible source of supply because scarcely one of the neutral countries can be classed as a manufacturing country. Spain has one or two factories and there are one or two in the Scandinavian countries.

With such a favorable market it is no credit to U. S. A. manufacturers that we are getting the business because there is no other place to buy cars. We are to-day selling our cars cash against document in New York. Generally European dealers are disappointed that our manufacturers have not made active steps toward establishing a more liberal basis of doing business with European neutrals. It would be to our credit to offer more favorable terms of payment now when we are not compelled because of international rivalry to do so. When the war is over international rivalry will require us to give better credit terms, perhaps 90 days. European dealers will then not thank us for giving credit extension because they will realize we will have to do it.

It is further expected by European dealers that we will lay more constructive plans for giving better service throughout Europe. With our highly-developed automobiles using essentially U. S. A. electric starting and lighting systems, a much better service is required. To date our parts manufacturers have done very little to establish that service which is necessary in Europe for their electrical systems. This applies to ignition systems, batteries, starters, generators and horns.

PETER STEENSTRUP
Hupmobile Representative for Europe and Latin-America

This lack of service is bound to react on us as soon as European manufacturers are back in the field. To-day is the time when we should prepare to meet the post-war competition, rather than waiting until terms of peace have been signed.

The question of getting pneumatic tires from neutral countries is one of the greatest obstacles in European car business at present. Norway and Sweden are particularly hampered in this respect to-day. This is due to the fact that during 1915 there was a great deal of smuggling of tires from Sweden to Germany, and now Great Britain, which holds the key to the tire situation for Europe, is getting even and will not ship tires or permit them to be shipped to Sweden. You can ship as many cars without tires as necessary. There is no prohibition of cars, but tires are under the ban. When tires are received they reach these countries in small instalments. In August no licenses for shipping tires into Sweden had been granted for several months.

To-day in Sweden it costs the price of a Ford car in the U. S. A. to buy a set of tires. I saw a dealer in Stockholm on Aug. 10 pay $167 U. S. gold for a 34 by 4 casing. I saw $12 paid for an old 34 by 4 inner tube, with fourteen patches. In addition to tires being very expensive, gasoline is retailing at from 50 to 75 cents per gallon.

There is a possibility that Jan. 1, 1917, may bring some relief in the tire situation with these countries. On that date Great Britain's conventions or arrangements with neutral countries, with regard to automobile tires, expires. It is rumored on good authority that Great Britain by that time will be willing to permit shipments of cars with tires into many neutral countries. If such is permitted it will greatly increase the sale of U. S. A. cars in Scandinavian countries.

The sale of U. S. A. cars in England, France and Italy is practically suspended, except to the governments. The sale of cars in England and Italy, except to the government, is forbidden. You can still sell in France by paying a 70 per cent import duty which is practically equivalent to an embargo.

Among the neutral countries, Switzerland would gladly buy cars but is practically prevented from doing so by the British blockade. Very few outside cars get into the country. What cars Switzerland is building to-day are largely being required by the government.

Business Booms in Spain

Spain is one of the neutral countries where the automobile business is thriving. The country is profiting because of the war and the government is aware of the fact that automobiles and motor trucks are as essential in war as guns and ammunition. The sale of cars in Spain is generally handled from Madrid. Outside of the capital Barcelona is the leading city, and is the greatest manufacturing center in Spain, being known as the Manchester of that country. In the Barcelona zone are more industries than any other part of the country. The city has a population of 560,000 and the streets are well paved.

In Barcelona is the factory of the Spanish automobile company where the Hispano-Suiza car is made. King Alfonso is one of the large stockholders in this concern and the output is largely absorbed by the government. The factory is producing several hundred cars per month, all being four-cylinder models.

Spanish Roads Poor

Spanish roads are generally not good. In the northern country in the summer resort district of San Sebastian are good macadam roads. Outside of large cities macadam roads radiate for upward of 50 miles. Once beyond this zone roads are sandy and rocky. To-day touring in Spain is looked upon as a stunt rather than a pleasure.

U. S. A. cars are selling in good quantities in Spain to-day. Fully 75 per cent of our cars are sold in cities. This is largely due to the fact that city people have profited most by the war. Spain in general wants five-passenger cars. Throughout the country are many body-builders who build closed types as needed. Gasoline is selling at from 50 to 60 cents.

Of neutral countries, perhaps Denmark has profited as much by the war as any other country. It is reported she has made enough to pay off her entire national debt. I was not able to visit Holland, for when I got to England for the second time after traveling through several continental countries, the English government decided I had traveled and seen enough, and would not let me into Holland. I was permitted to go to Norway, Sweden and Denmark, but my passport was stamped "No return to England," so I had to return direct to America from the Scandinavian countries.

The Scandinavian countries, that is Norway and Sweden, including Denmark, have made their money out of various products that have been sold to Allies and Teutons. They let Germany bid against England, and sell to the highest bidder. Some of the products most in demand are foods, fish, minerals and lumber.

Before placing an absolute embargo on the importation of automobiles, England was doing all she could to discourage the use of motor cars for pleasure. Among the emphatic means employed by the British Government in this regard may be mentioned, thousands of huge posters plastered all over London accusing people who used automobiles for pleasure of being "Germans."

Norway a Growing Market

Great Britain is making the best possible use of her sea power to control the movement of all sorts of supplies which might ultimately reach her enemies. Before our automobile exporters complain of Great Britain's efforts to regulate the movement of tires they probably do not know to what extent nearly every line of trade of the small neutral countries are regulated. Norway was prevented for a long time from importing cotton and could obtain it only by agreeing that it would not be used for making fish yarns. In that way Great Britain could regulate the catch of fish and thus indirectly at least prevent this class of foodstuffs reaching Germany in too great quantities. Fish bring high prices in Germany and the unlimited catch and sale of same to Germany would make many more small fortunes in Norway and consequent increased sales of automobiles.

Willys-Overland's New Headquarters

(*Continued from page* 660)

the women's rest room, with a graduate nurse attendant is located here; and other hospital arrangements are on this floor. It is the most convenient, being half way up and down, for the stenographic force which goes up or down to the different offices as required, also for filing, etc.

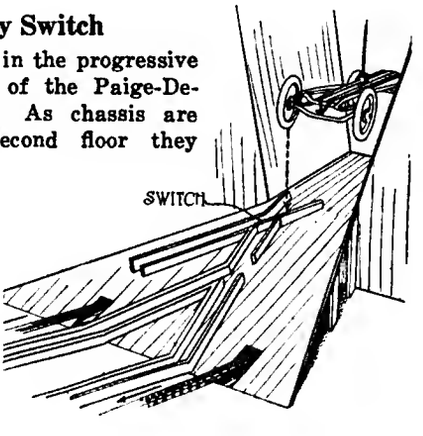
Fourth floor, that is first above the central one, is given over entirely to sales departments, including separate offices for all the departments of sales.

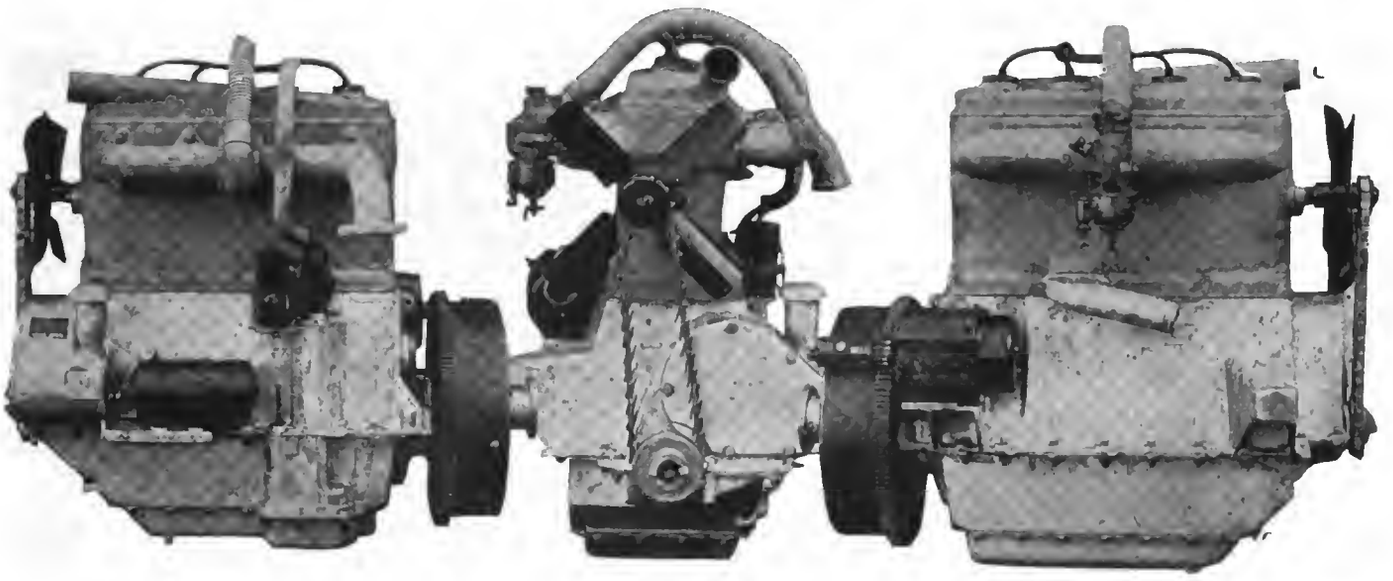
Fifth floor is devoted exclusively to offices of the executives of the firm and board rooms. On this floor the office of President John N. Willys is finished in walnut, and is a model of its kind. The board room, similarly finished, has panelled walnut walls, and the customary ponderous table extending from end to end which carries the atmosphere of a bank board room. All of the vice-presidents and other officers have offices on this floor.

The sixth, or top floor, is a huge cafeteria, with capacity for 200 persons every 30 min. This cafeteria occupies but one-half the floor, the other half being a large auditorium with seating capacity for 600, a stage at one end for moving picture programs, and a dancing floor. The cafeteria has been carefully worked out so as to give efficiency. The luncheon hour ranges from 11:30 to 2 o'clock. It is handled in 30 min. relays. One division of the office takes luncheon 11:30 to 12:30; another 12 to 1; another 12:30 to 1:30; and the fourth 1 to 2. Luncheon prices are very low. The prices are: Meat orders 9 cents; soups 5 cents; vegetables 4 cents; dessert 5 cents; coffee, milk or tea 3 cents. Coupon books worth $2 are used in payment.

An Efficiency Switch

THIS switch is used in the progressive assembly system of the Paige-Detroit Motor Car Co. As chassis are lowered from the second floor they are switched to the right or left track as required. There are two tracks on the lower floor and the switch enables the chassis to be evenly distributed.





Moline-Knight engine, showing mounting of 6-volt Wagner generator with grounded return, which replaces a 12-volt two-wire type. Also Connecticut ignition distributer which supplants a magneto. Note Auto-Lite starting motor and hot air stove for carbureter

Moline Makes Engine Changes

Abandons Oil Pressure Control—Adopts Battery Ignition in Place of Magneto—Front End Chain Layout Rearranged

THE new model G Moline-Knight four, while it follows the lines of the last model, has several changes in detail, especially with respect to the engine. This is, of course, a Knight type, and the dimensions of 4 by 6 in. are unchanged, but the detail has been modified at a good number of points. The most immediately noticeable change is that the magneto has been replaced by Connecticut battery ignition. The distributer is worm-driven off of the eccentric shaft, which actuates the sliding sleeves, and the same shaft which drives the distributer extends into the crankcase and drives a new type of oil pump which is another departure from Moline practice.

Oil pressure in the Moline-Knight is no longer controlled by the carbureter throttle. In the previous models a lever in unit with the throttle lever opened and closed an oil pump throttle with the purpose of giving a uniform addition of oil pressure with the acceleration of the car. In a few instances it was found that owners had difficulty in understanding this arrangement and abused it by mis-adjustment, consequently a gear-pump has been substituted which gives increased oil pressure as its speed increases.

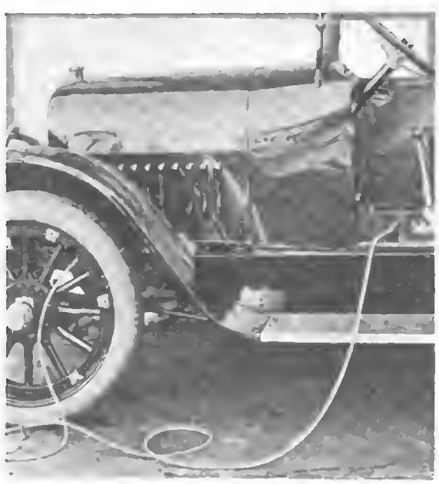
The silent-chain system for the front end is no longer a triangular layout. In the model 50 one chain acted through three sprockets, a drive sprocket, sleeve-actuating sprocket and generator-driving sprocket. The new method is to drive the sleeve shaft by one chain and the generator with another.

The exhaust manifold is now constructed to permit the separate exit of gases from each of the four cylinders, this being accomplished by the use of a casting with ports to each cylinder, which replaces a manifold that took care of two cylinders in one part. Better scavenging is the claim for the new principle.

The new intake assembly embodies a hot-air pipe which reaches over the top of the cylinders and connects on one end with a stove on the exhaust manifold and on the other with the air intake of the carbureter. The stove assembly is purely a cold weather fixture and the makers state that it should be removed for summer driving.

The new crankcase is built in halves instead of one casting as in the 1916 model 50. Maximum accessibility is claimed for this construction because it is only necessary to remove the oil pan to permit the complete removal of all the connecting-rods and pistons.

Another step in the way of accessibility is the new location of the combination oil filler and breather pipe, this having been located on the crankcase arm instead of in the center. With the old design the oil filler came directly under the water pipe, making it somewhat difficult to pour in the oil. The cast-aluminum fan has been discontinued and in its place is a pressed steel fan operating on a swinging bracket which permits ready belt adjustment.



Moline-Knight tire-pump hose may be attached without lifting the floorboards

All the above mentioned features constitute a change of the larger car to comply more nearly with the specifications of design of the model 40, which was the small car of last year. This latter will be continued with a few alterations which will be announced later.

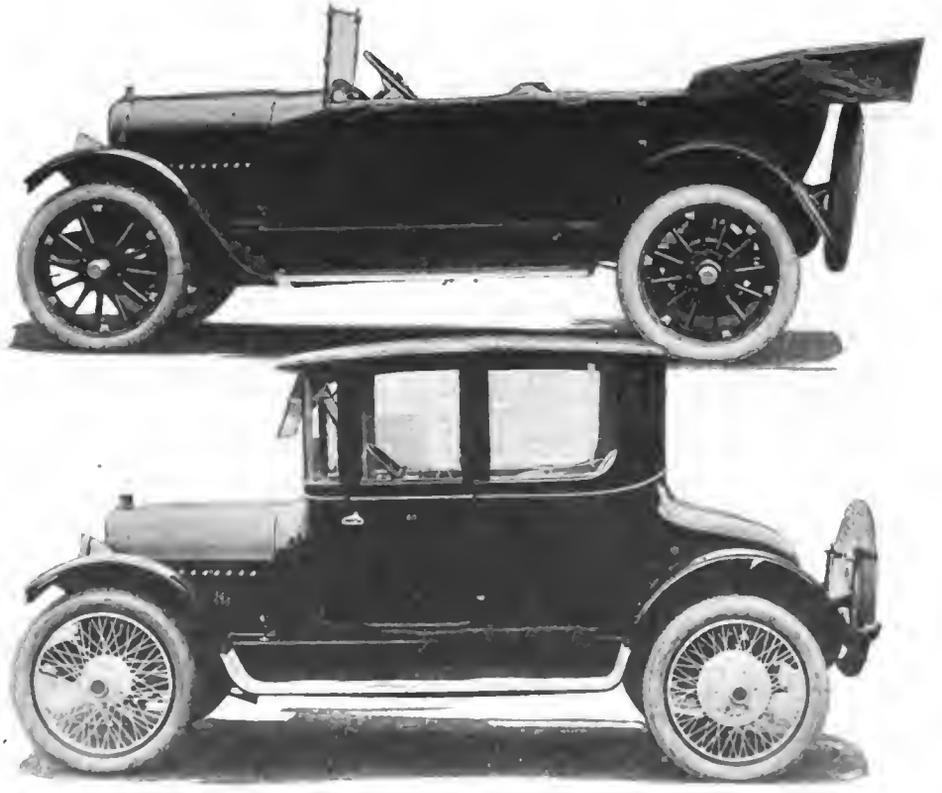
Something entirely new, however, is the adoption of the Bendix system of starting-motor drive in place of the manual shift which has characterized previous models. This was adopted because of its simplicity, there being less parts in the Bendix shaft assembly than in the manual shifting device. In

the electrical system, there is another marked change from the model 50 equipment. The generator is still a Wagner, but it is a 6-volt instead of a 12-volt machine and the wiring has the ground return principle instead of the two-wire system of the previous model. This is another step toward simplicity which has been the goal of the Moline engineering staff in the building up of this new model. The starting motor is an Auto-Lite design.

Moline Universals Used

The Brown-Lipe three-speed selective transmission is still mounted some distance behind the engine and is connected with it through two universals. These universals, however, are of Moline make in this latest model.

The rear axle is a floating type with spiral bevel drive, much the same in construction as on the model 40, but proportionately larger to take care of the additional power and weight in the new car. The gear reduction in the differential is 4 to 1 instead of 4.33 to 1, this higher gearing being made possible by the decreased weight, with an engine of the same size and even higher efficiency. The front axle is a duplicate of the large car of 1916.



Above is the new double-cowl touring body fitted to the new Moline-Knight chassis and below the new coupé with wire wheels

The characteristic double-compounded semi-elliptic spring design is retained in the model G. The springs are transverse and there are two of them, one above the other. They are of slightly different length and so different deflection period. The upper has a shackle attachment to the frame at one end and a pin at the other, and the lower has corresponding attachments to the axle. The effect of these two springs is to provide a very flexible suspension and yet roll and jumping is eliminated by the difference in deflection period. One spring damps the other, so to speak, when a severe shock is encountered.

Stewart Vacuum Fuel Feed

A new accessory which alters another principle of design is the installation of a Stewart vacuum tank which supplants the pressure system of the model 50. Gasoline is contained in a round tank instead of a square one and this tank is ingeniously fitted into the rear frame assembly and held in place by steel straps. The tank is fitted with a magnetic gasoline gage.

The Brush chassis and frame design in which the side members of the frame were extended to form the running boards is not evident in this model. Instead, the running boards are of wood. The shape of the frame, however, is similar to the previous model with the size altered to take care of the new chassis.

The tire pump mounting shows another well-planned effort to bring all accessories within easy reach. This accessory is now mounted on the gearset, so that the hose may be screwed into the nozzle without lifting the floorboards. The pump-operating lever is located at the side of the gear-shifting lever. In previous models the pump was under the hood and driven from the fan gear.

Double-Cowl Body

The new body marks Moline's acceptance of the double cowl. It is by far the best appearing body that these makers have yet produced. With a rolled-in edge sloping into the rear cowl, a rounded back, front cowl blending into the hood, crowned fenders and the characteristic all-curved line Moline-Knight radiator, the new car is entirely lacking in straight lines and has a massive, comfortable appearance. The sides of the body are 1½ in. higher than in the model 50, permitting lower seating of the passengers within the body which is becoming so much in demand. The upholstery is buttonless and deep. A mahogany panel has been fitted on the back of the rear cowl and in this are two flush rear-seat lights, one on each side. The windshield has been given a slight slant, hardly perceptible yet just enough to further carry out the effect of a total absence of right angles.

The spare tire is carried on a ring which serves the same purpose as a rim; that is, the tire and demountable rim are bolted directly onto it. A locking device is fitted, and this same assembly carries the tail lamp and license bracket. Because of its lighter weight the model G is fitted with 35 by 4½ in. tires instead of 36 by 4½, which size was standard on the model 50. With full equipment the model G sells for $1,750.

—

Willys-Overland 75-B Delivery Car

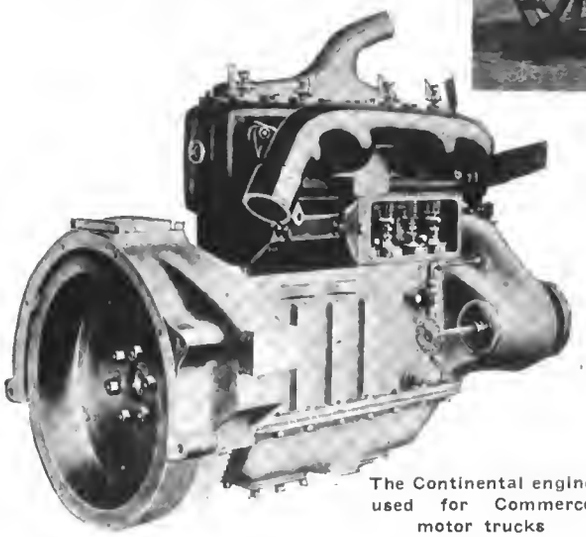
TOLEDO, OHIO, Oct. 16—The Willys-Overland Co. has put on the market the new Overland 75-B chassis fitted with a panel delivery body, selling at $625 f.o.b. Toledo. Features of the chassis which are not commonly found in low-priced delivery cars are the four-cylinder 31½-hp. block engine, electric starting and lighting system and 31 by 4 in. tires.

The panel delivery body fitted provides more than 78 cu. ft. of loading space back of the car. As the driver's seat extends only half way across the car there is additional space available extending to the toe board if required, the entire length of the floor on that side of the car being 97 in. The car is light and compactly built, has a short turning radius, making it easy to handle under all sorts of traffic conditions, and is designed to be economical in operation and maintenance. Tests have shown that it will run in continuous service at a cost of 1 cent or less per mile for gasoline and oil, according to the manufacturer.

Commerce Adds 1-Ton Model

Complete Electric Equipment Includes Starter—1-Ton Has Internal Gear and 1500-lb. Model Uses Bevel Drive—Power Plants Employed Are Identical

A 1-ton Commerce chassis selling at $1,175 with open body costing $60



The Continental engine used for Commerce motor trucks

IN addition to the 1500-lb. wagon, the Commerce Motor Car Co., Detroit, is now marketing a 1-ton truck. This is the first departure of this concern, which has been manufacturing vehicles for 7 years, from a single model policy and marks its entrance into a new field of light commercial car work.

Following the customary practice in light-capacity trucks the Commerce 1-ton model E is sold as a chassis, completely equipped with electric starting and lighting and a governor. This list price is $1,175 for the chassis alone and to this may be fitted a wide range of body styles. As standard the Commerce company is marketing an open body at $60 and a body with a four-post top and storm curtains at $100. Deliveries on this vehicle are scheduled for Nov. 15.

As far as the powerplant is concerned this truck is the same as the 1500-lb. chassis with the Continental unit, having a block of four cylinders 3½ in. by 5 in. This is an L-head design of medium duty characteristics and carries the clutch and gearset as a unit plant. Conventional design is used throughout and a good index to the construction of the engine is given in the main bearing dimensions which are: front, 2 3/16 by 2⅞; center, 2 7/32 by 2½ and rear, 2¼ by 3. This gives a minimum crankshaft diameter at the bearings of 2¼ in.

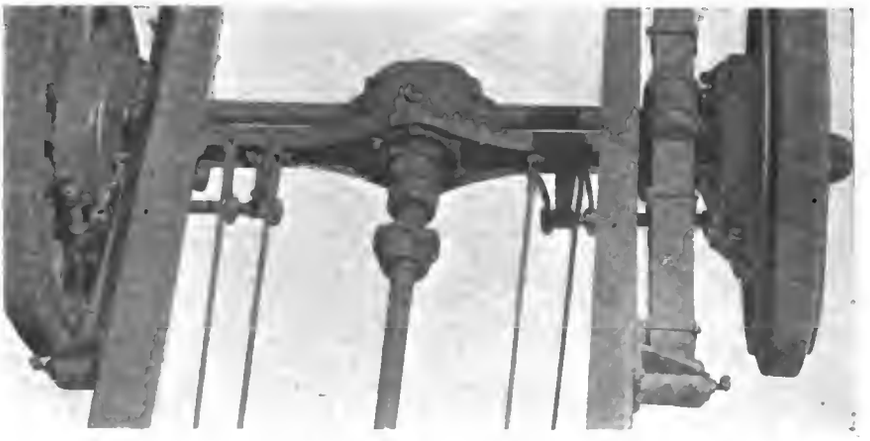
Following the dictates of common-sense in truck motor practice everything about the power plant is as simple as it is possible to make it. The oiling system for instance is a simple splash in which a constant level is maintained by a plunger pump. The only attention that the oiling system requires is to keep it filled with oil to the proper level, and occasionally to flush the crankcase with kerosene. The capacity of the reservoir which is in the lower part of the crankcase is 1 gal.

Fool-proof Ignition System

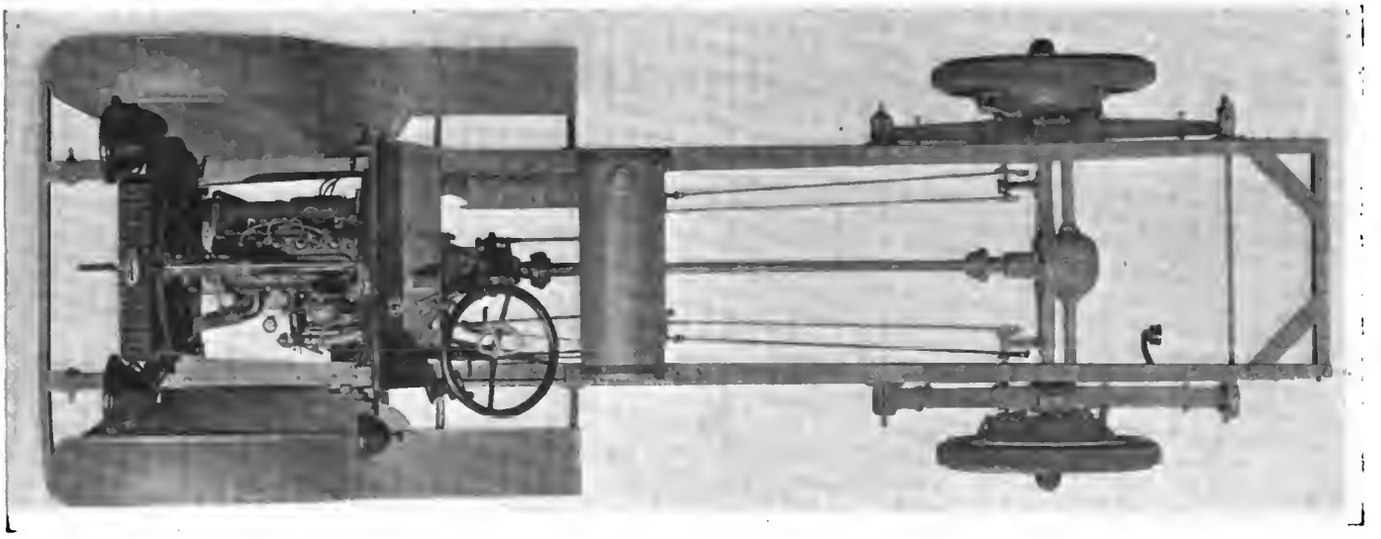
The ignition system is also a fool-proof installation, being a single high-tension Eisemann magneto with even the spark lever removed, as the timing of the ignition is fixed. Cooling is by thermo-syphon in connection with a vertical finned tube radiator with a removable cast top. The radiator construction is qute interesting, being an up-to-date adaptation of the cast tank and side member design. The component parts are illustrated herewith.

Three-Speed Gearset

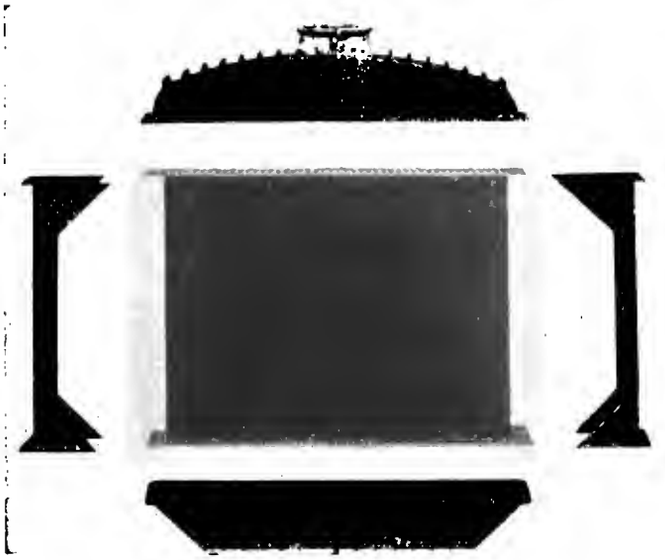
In the bolted-on bell housing are a leather-faced cone clutch and a three-speed selective gearset. From these the drive is transmitted through a propeller shaft and universal joint set manufactured by the Arvac Mfg. Co. The joints are made of drop forgings with felt washers and circular wire springs for retaining the grease. The shaft is hollow, having an outside diameter of 1¾-in. and a wall thickness of 3/16 in. From the rear universal the drive is transmitted to a Torbenson internal gear rear drive carried on roller bearings of Bower and Bock manufacture. A heavy wheel is used with 1¾-in. square spokes and the regular tire equipment is solid rubber of 34 by 3 front and 34 by 4 rear. When pneumatic tires are fitted at an extra cost, the tire



Rear construction of Commerce 1-ton chassis



Showing the substantial simplicity of the Commerce 1-ton chassis



Commerce special form of radiator

sizes are 34 by 4½ front and 35 by 5 rear. The front axle is an I-beam and it is equipped with Bower roller bearings in the hubs.

The frame is a high-carbon steel of channel section. The thickness of the stock is 3/16 in. and, as this material has a tensile strength of from 60,000 to 80,000 lb. per square inch, a high factor of safety is allowed with the depth of 4½ in. The flange width on this frame varies in regards to its position on the car. At the front end it is 2¼ in. at the center 3½ and at the rear 2, giving lateral as well as vertical stiffness.

A double set of concentric brakes is used on the rear wheels. The internal is 15½ by 2¼ in. and the external 16 by 2½ in. These are connected with the brake control mechanism by direct-line linkage and are secured against rattles. The spring eyes and shackles are also secured against wear and looseness by using bronze bushings at all points and protecting these by oil cups.

In the way of fittings and equipment the car is unusually complete for a commercial vehicle. The Remy electric equipment is used for starting and lighting in connection with a Willard storage battery. The carbureter is a Zenith which is also in line with the simplicity of the entire chassis as there are no adjustment points beyond those fixed at the factory. For gasoline feed the Stewart vacuum system is used, operating in connection with a 15-gal. welded steel tank located beneath the driver's seat. The lamp equipment consists of side and tail running lights with a powerful searchlight for picking up house numbers, street signs, etc. The standard bodies have a loading space of 44 by 110 in.

Automobile Performance

(*Continued from page* 659)

J. B. Replogel, director of research, Remy company, asked what we would do with the formula after we got it. The *C* factor must be taken into consideration and therefore we would have to assume units for noise, vibration and endurance.

William B. Stout, sales manager Scripps-Booth, said that in all probability the *C*, or comfort factor, would be the deciding one. It would be impossible to reach the same effect by formula that riding in the car would secure. A formula also leaves out the element of personality, which is largely to be desired and which is a factor in the sales of a car company in the same way as it is of a piano concern. Even the height of the car is responsible for impression in riding and Mr. Stout pointed out that the effect of riding in a car which is too high or too low has the effect of nervous strain which produces mental fatigue that would never be registered in the performance formula.

C. C. Hinkley, engineer of the Chalmers company, stated that when cars are designed they are designed around a formula and for that reason there is no good reason why the same formula could not be used as a rating method. The formula he uses is:

$$\frac{\frac{D \times R}{W \times d}}{T}$$

Where *D*, is displacement, *R* is gear ratio; *W*, weight; *d*, wheel diameter and *T*, the time in seconds necessary to accelerate from 5 to 50 m.p.h.

V. R. Heftler, president of the Zenith Carbureter Co., stated that it may after all be better to give performance rating in the form of a curve rather than in a mathematical expression.

E. M. Planche, chief engineer of the Dort company, stated that he used the $S \times A \times E$ formula divided by *L*, the low, high-gear performance with very good results. The wind resistance factor should also be regarded important.

O. E. Hunt, assistant engineer of the Packard company, said, "No engineer would contend that performance is the sum total of car value. Besides this it is made up of reliability, comfort and appearance. The factors involved in performance are speed range, acceleration and economy, *i.e.*, *S. A.* and *E.* Only the latter can be measured mathematically and can be considered in a formula."

Fuel Feed By New Method

Cylinder Pressure Employed To Fill Supplementary Tank in Turn Feeding Carbureter by Gravity

THE Church fuel feed system is a new method combining gravity and pressure feed in an ingenious way. It involves a supplementary fuel tank which may be mounted on the dash or other convenient point, and from this gasoline is fed directly by gravity to the carbureter. A float level is maintained within the supplementary dash tank.

It differs from one other system in that instead of using the suction of the engine to transfer fuel from the main tank to the auxiliary tank, this is maintained by an automatically regulated pressure caused by the compression and explosion pressure in one cylinder. This pressure is obtained through a very ingenious check valve mounted usually in place of the petcock in the rear cylinder and through which the burned gases maintain pressure on the main fuel tank and force gasoline to the auxiliary tank in the same way that fuel is forced directly to the carbureter in the conventional pressure system.

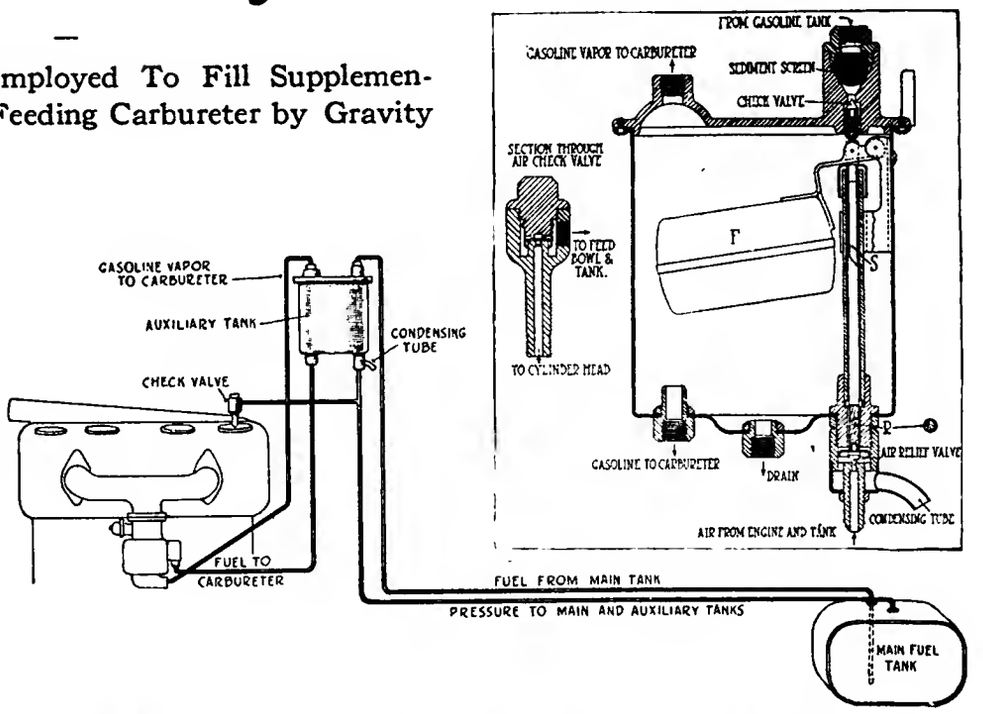


Diagram of Church fuel feed system with a section through the auxiliary tank

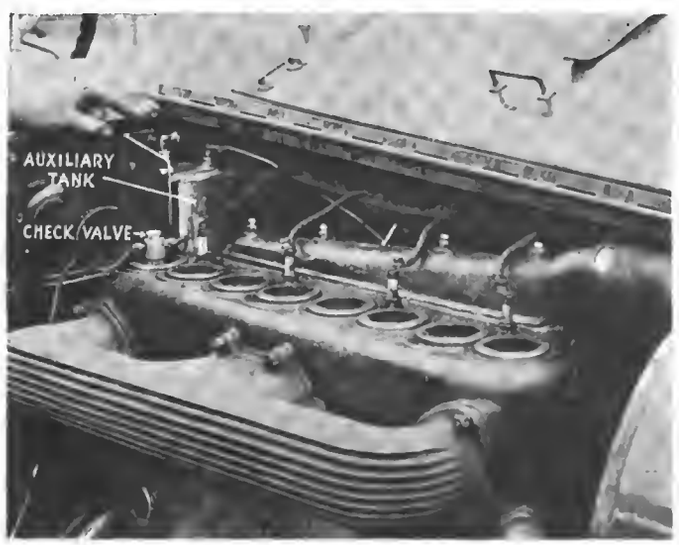
It has the distinction, however, that a constant gravity feed is provided to the carbureter and there is no hand-pump required.

A feature of the system, which will have the most general appeal, is the fact that an adequate supply of gasoline is assured to the carbureter, even though the auxiliary tank be empty at the time of start, and even though the main fuel tank may have been open for filling and the pressure thus relieved. This comes about through the fact, first, that the fuel in the carbureter float chamber is more than sufficient to start the gasoline running from the main tank to the auxiliary tank, where it runs by gravity to the carbureter and, second, that in the absence of sufficient fuel in the carbureter float chamber to start the engine, the operation of the starter for 15 sec. or less will generate pressure sufficient to put fuel in the auxiliary tank.



Church fuel feed system on engine, showing auxiliary tank on dash. Note check valve

Flow Is Constant

A point that is considered most important by the inventor is the fact that, being independent of engine suction, the engine can be run indefinitely on wide-open throttle without diminution in the fuel supply, caused by the combined decrease in suction and increase in fuel demand which occurs with wide-open throttle. On the contrary, the system is arranged so that increased demand on the auxiliary tank automatically permits increased pressure in the main tank, thus increasing the flow of fuel to the auxiliary tank.

That the system is capable of supplying fuel under conditions of maximum demand was demonstrated recently in an official A. A. A. test on the Chicago Speedway under the direct supervision of F. E. Edwards of the A. A. A. technical committee, and witnessed by a representative of THE AUTOMOBILE. In this test, a Mercer 22-70 roadster, fitted with the Church system was driven a distance of 10 miles in a total elapsed time of 7 min. and 58.4 sec., an average speed of 75.4 m.p.h., with a maximum speedometer reading of 84 m.p.h. As may be imagined, this required wide-open throttle practically the entire 10 miles, and there was no spitting or other evidence of starvation during the trial. At the end of this distance the auxiliary tank was still full.

The system is arranged so that the ordinary maximum pressure is not over 1½ lb. per square inch, but in the test referred to, the pressure as indicated by a gage on the dash, ran up to nearly 3 lb. indicating the automatic increase in pressure to meet an increased demand. In order to further illustrate this point, a Jeffery six touring car was fitted with a mast, upon the top of which the Church tank was installed, so that the tank was 10 ft. 9 in. above the level of the main

tank. With the auxiliary tank empty, pressure relieved from the main tank and the engine dead, it required 14.4 sec. to get fuel into the auxiliary tank after the starter button was depressed, at the end of which time the pressure indicator showed a pressure of 1⅓ lb. per square inch. In running the car at a speed of 55 m.p.h. a maximum pressure of 3 lb. was registered.

Essentially a Closed System

Another advantage with which the system may be credited comes from the fact that the system is essentially a closed system, and neither the main tank nor the auxiliary tank is open to the air; consequently, there is no chance of taking in road dust. The system is closed in another respect, in that a vent is provided in the top of the auxiliary tank, but this vent is connected to the air intake of the carbureter, so that any gas which evaporates from the system passes directly into the carbureter through the air intake, and thus adds its quota to the fuel supply instead of being wasted. Inasmuch as the evaporation of gasoline over a warm engine is a considerable fraction of the fuel possibility, this feature is an item of economy.

The diagram on the opposite page shows the general layout of the system, together with a cross-section of the Church tank on the right, and the air check valve on the left, while the illustration at the bottom of the page shows the tank installed on a Mercer car. In the sectional view it will be noticed that the pressure line is in the form of an inverted T with the check valve at one end, the main tank at the other and the Church tank at the end of the stem. It is in the Church tank that the pressure regulation occurs, and it is determined by the position of the float *F*. As the float descends with lowering of the gasoline level, the stem *S* moves downward, pushing downward on pushrod *R*. This in turn seats the air relief valve and prevents pressure escaping through the condensing tube, so that, with the float in its lowest position, all of the pressure from the check valve goes into the main tank.

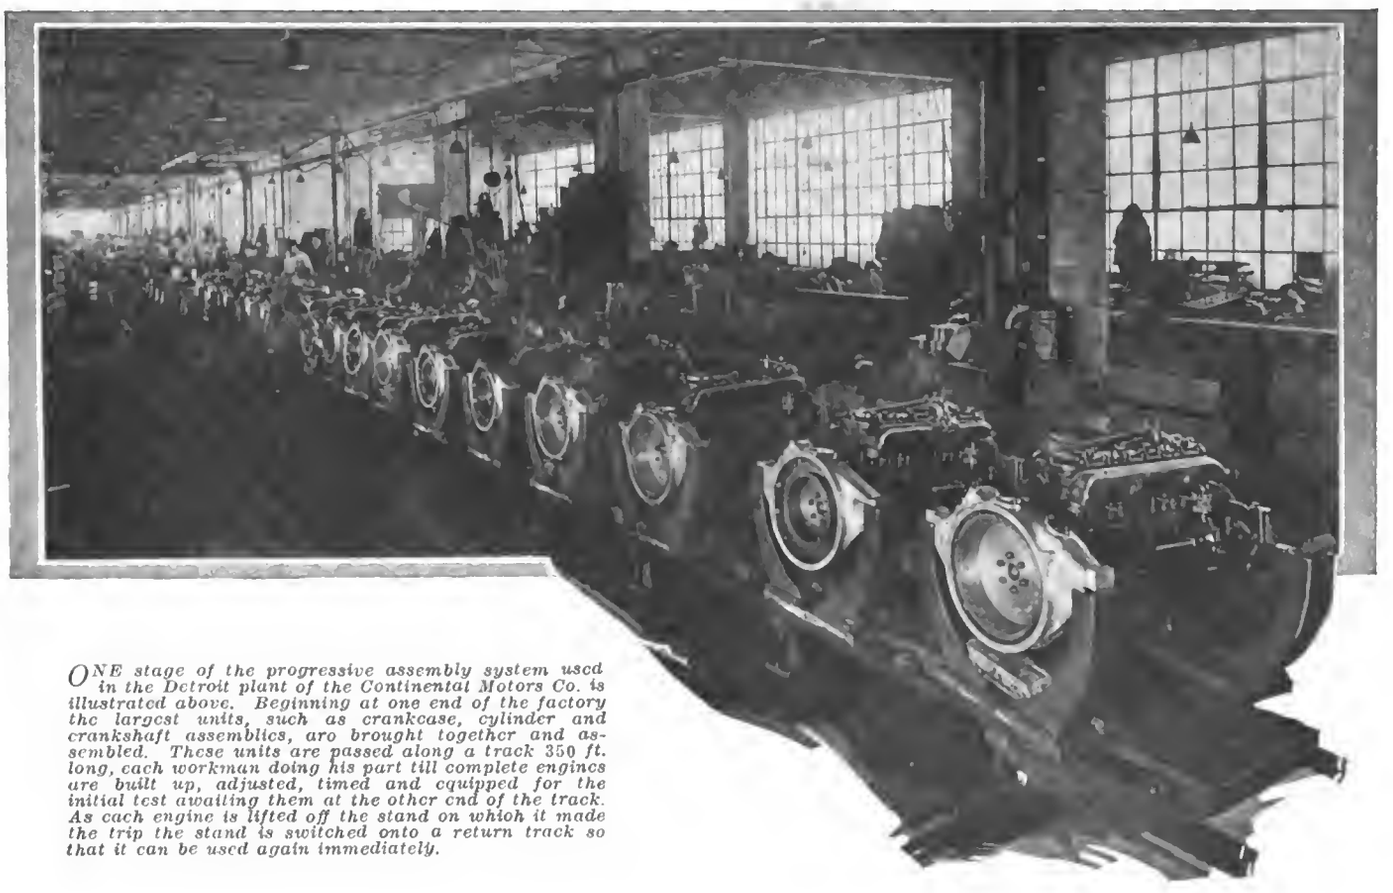
When the float is at its upper position, the air relief valve is forced upward by the pressure, permitting the latter to escape through the condensing tube. The conical form of the air relief valve graduates the amount of pressure being used in proportion to the position of the float; that is, in proportion to the height of the gasoline level in the auxiliary tank. It will be noted that a gasoline check valve is provided at the gasoline intake operating in harmony with the air relief valve. It will also be noted that cleaning arrangements are accessible, for the sediment screen can be removed without disturbing the tank, as can the air relief valve.

The designer attributes the possibility of this system to the design of the check valve. This is a flat nickel disk, 1/32 in. thick, and having a maximum opening of only 0.003 in. It is calculated that the valve takes approximately 0.005 of the cylinder volume.

Sight Feed Furnished

In connection with the system a gasoline sight feed on the dash is supplied if desired, and this has the advantage of giving a warning that the main tank is empty, at which time there is approximately a pint of fuel in the auxiliary tank which serves as a reserve. The system was developed by Edmund S. Church, Automatic Carbureter Co., Chicago, Ill.

Progressive Assembly Used for Continental Engines



ONE stage of the progressive assembly system used in the Detroit plant of the Continental Motors Co. is illustrated above. Beginning at one end of the factory the largest units, such as crankcase, cylinder and crankshaft assemblies, are brought together and assembled. These units are passed along a track 350 ft. long, each workman doing his part till complete engines are built up, adjusted, timed and equipped for the initial test awaiting them at the other end of the track. As each engine is lifted off the stand on which it made the trip the stand is switched onto a return track so that it can be used again immediately.

A corner of the Studebaker custom body department, showing bodies being trimmed

Studebaker Custom Bodies

Demand for Special Styles Leads Factory To Install Custom Department—Represents Saving

BUYERS of Studebaker cars are no longer confined to the limitations of stock bodies. Owing to the increasing demand for individuality in external appearance, as manifested on the part of purchasers of its cars, the Studebaker company has made the departure of incorporating within its plant a custom body department in which the range of ideas of purchasers can be met with a corresponding style of body in both open and closed models.

Heretofore automobile manufacturers who are classed among the big producers have done a relatively small amount of custom business and where it has been done the bodies have been bought from builders outside the organization. In 1913 the Studebaker company started a body department of its own in which the stock bodies were made, but up to the present time the custom-made bodies have been purchased on the outside.

During the last year there has been a rapidly increasing demand for special body design and it has been felt that the expense of organizing the custom body department will be immediately met by the increasing demand for these bodies. This has already proven to be the case.

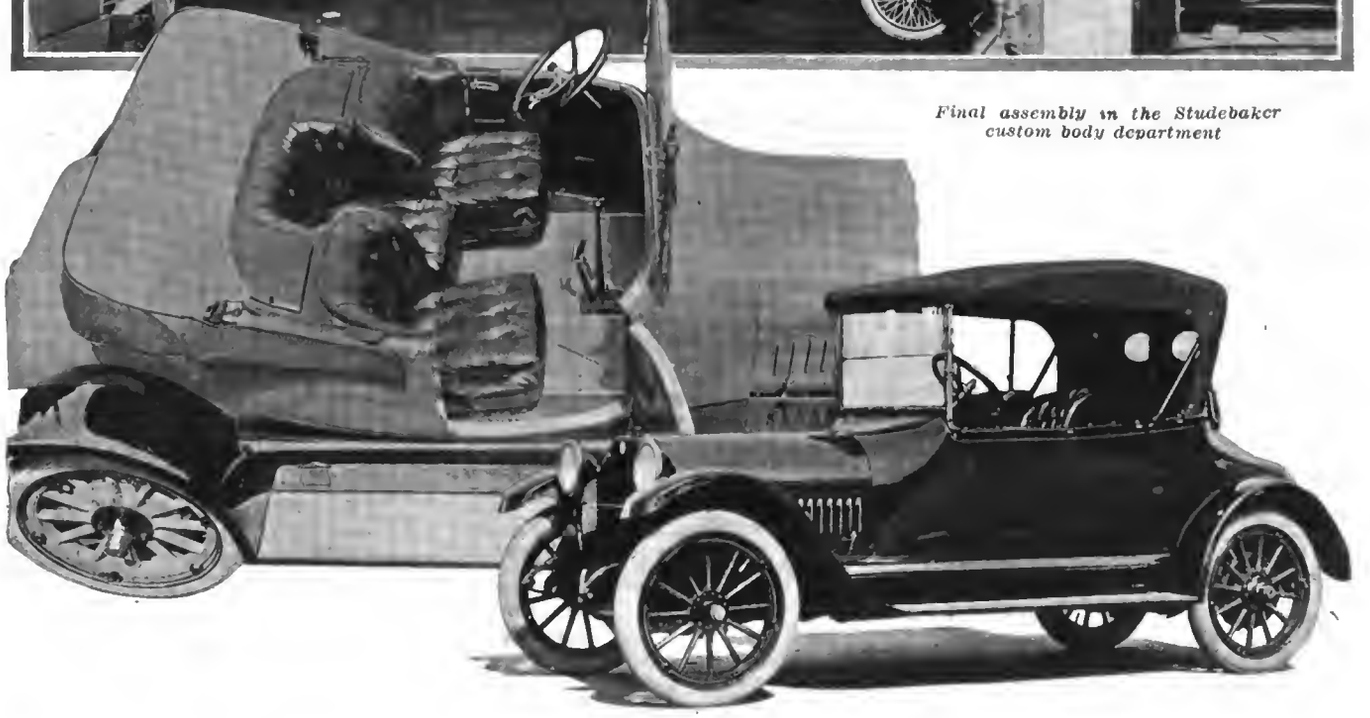
The method of procedure in securing the specially-built bodies is for the purchaser to describe the type he desires. He is then furnished with a rough sketch prepared by the Studebaker designers and when this is approved it is drawn to full size before the structural drawings are made. In carrying out the work of producing these new bodies, several distinctive shapes have been created, and in each case special style tops have been designed to accommodate the body contour.

Of chief interest to the purchasers is the fact that the selling price of the completed product is below the combined price of the chassis and a similar body purchased outside because of the elimination of the middleman's profit. The deviations from the stock body are not only in shape and seating arrangement, but also in color. The standard body is dark blue, while the custom-made bodies are finished in any color scheme that may be desired. The materials used in the construction of these special bodies are carefully selected in the same manner as they are by any of the custom body manufacturers, and although the price of these special jobs will range from $100 to several hundred dollars more than the stock body, there is an ever increasing number of buyers who are willing to pay the difference.

Some of the special bodies which have already been produced are shown in the accompanying illustrations. One of these is a three-passenger cloverleaf roadster which is characterized by the fact that the center seat is not placed as far back as is usual in the three-passenger cloverleafs and hence allows a maximum amount of sociability in seating with the minimum of body length. The small compartments formed on either side of the center seat by its staggered arrangement, which spaces are sometimes allowed to pass entirely unutilized, are utilized for package carriers and can be reached by lids which set

Where the metal-working is done. Bodies are of sheet aluminum

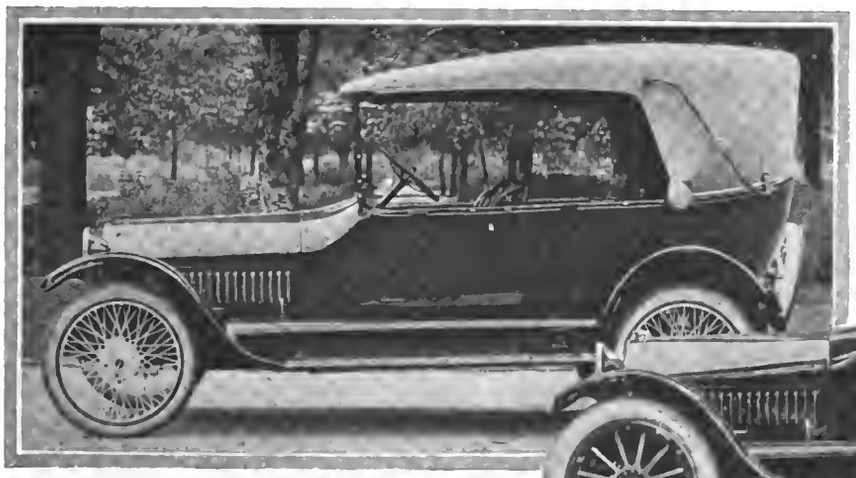
Final assembly in the Studebaker custom body department



Above at the left is a three-passenger cloverleaf type of body made in the Studebaker custom body department and fitted to a standard chassis

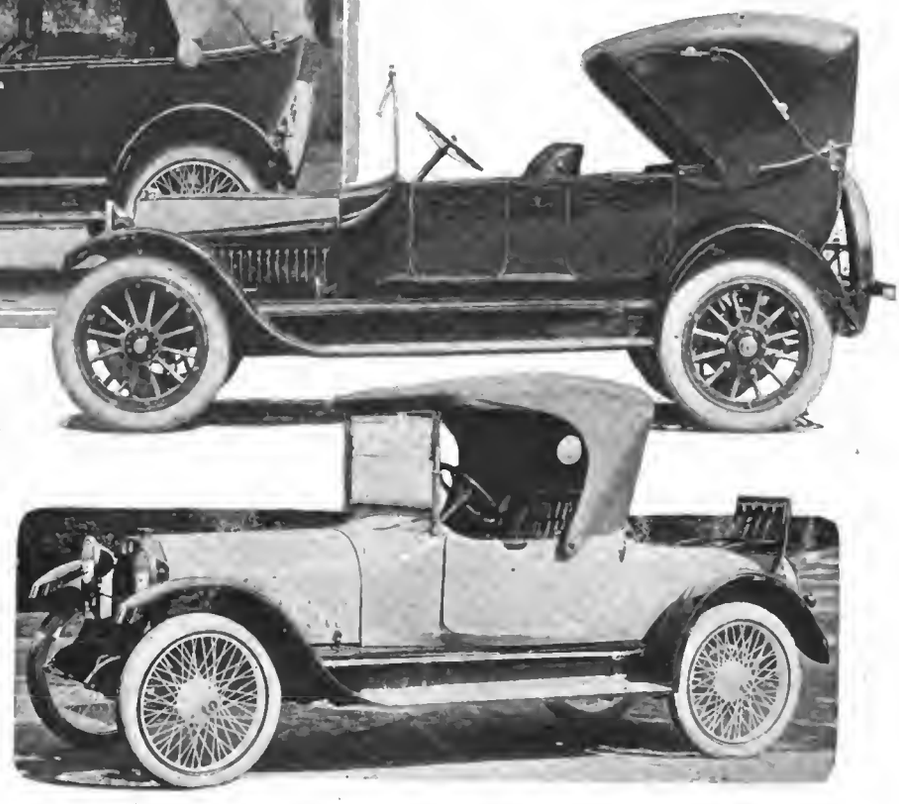
At the right is a custom-built four-passenger roadster design mounted on a Studebaker chassis. This car is entirely a product of the company's factory

At the left is a section of the wood-working shop in the new custom body department of the Studebaker factory. The sheet aluminum bodies are fitted over the wooden frames, parts of which appear in the illustration



The body illustrated at the right is a seven-passenger Studebaker model fitted with a victoria top

At the left is a seven-passenger touring body fitted with a Heaslet top, the latter being named after J. G. Heaslet, vice-president in charge of engineering and production. It is finished in red



A custom-made roadster produced by the Studebaker custom body department. Note the lackey seat in rear for a servant. When not in use this seat folds into the rear deck, leaving the surface smooth

in from the top, a convenient arrangement.

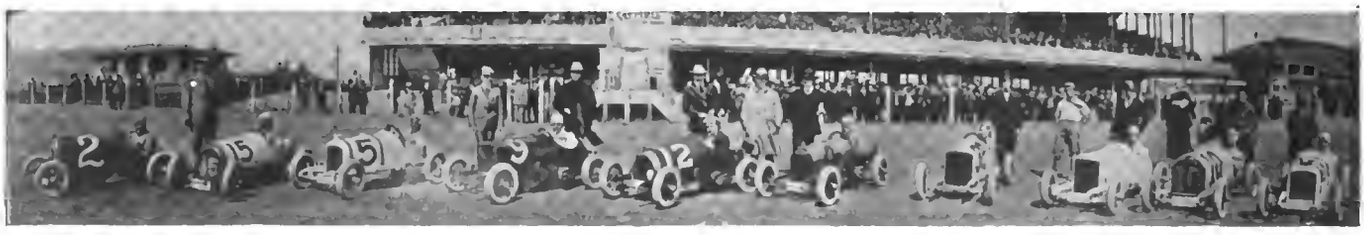
An example of special top construction is shown on a seven-passenger body. This is finished in red and the top itself is what might be called an extended victoria, as it opens with the exterior bows in the same manner as a victoria top, but the peak is extended to the top of the windshield. A top somewhat on this style is shown on a custom-made roadster body which is fitted with a rather novel lackey seat in the rear. The extra seat is primarily intended to accommodate a servant and when not in use it is folded down out of view. The feature of the seat is that the part which folds up uncovering the seat well forms a convenient back rest for the occupant. A particularly wide door is used on this model and the curvature of the side line of the body is also very well worked out.

In the way of special roadsters, the four-passenger design has proved to be quite popular. The type shown in the accompanying illustration is exceptionally roomy and almost approaches a close-coupled touring car with the exception that there are no rear doors, the entrance being through the front and between the divided front seats. No difficulty is found in seating two passengers in the rear seat of this body, as it is of generous width and far enough removed from the back of the front seat to allow the passengers plenty of knee room.

A rather staid and formal type of body is illustrated in the seven-passenger design with victoria top. This is a very popular design with ladies who utilize it for afternoon calls and shopping, giving an effect of an open town car. As will be noted, it is equipped with bumpers both in the front and rear, in order to take care of the minor collisions which often occur under conditions of crowded traffic.

Miniature Racing Cars Make 70 M.P.H.

TEN miniature racing cars, using Indian motorcycle engines and 20 by 4-in. Goodyear cord aeroplane tires on miniature wire wheels, attained a speed of 65 to 70 m.p.h. in a series of races held recently at San Francisco. As can be seen from the illustration published herewith, these little cars were constructed in accordance with the latest dictates of design as adopted in the standard speed creations now breaking records at over 100 m.p.h. on the speedway circuit. While very lightly built, they are made low to keep the center of gravity near the ground and the bodies are built to offer minimum resistance to the wind. Although the tires used were not built for race track service, they stood up excellently under the strains of high speed work, as experienced in the contests fought out by the Lilliputian racing cars.



Ten miniature racing cars which battled for supremacy in a series of races held recently at San Francisco

Resta Wins 250-Mile Grand American Race

(*Continued from page* 655)

Hudson to such an important position in the Sheepshead Bay Race, drove the last 150 miles on five cylinders, and finished in tenth position. He broke a bushing in the valve lifter assembly and after 20 minutes of frantic effort, he and his mechanic removed the lifter guide and re-entered the race with one valve in operation.

Nine Stops for Plugs

Spark plugs again had a hand in swelling the number of pit stops. There were nine stops for plug changes.

To-day was a day for fires at the Maywood track. The Crawford with its unlucky 13 was the only one which was serious, but the other two had possibilities of danger. Devore's Duesenberg caught on fire early in the race at the pit when the driver had flooded things in general in working with his carbureter. When he finally started the engine the gasoline around the engine caught fire from the backfire and a lively conflagration was started. Luckily this was almost in front of the J-M pit and the fire extinguishers had the flames out before they had gained any headway.

The other fire was an incipient conflagration which started from a carelessly thrown match or cigar in the bunting which decorated the front of the grandstand. Attendants had the burning bunting ripped off before any damage was done and there was little excitement in the grandstand. Probably only a few of the spectators, and those immediately behind the place where it occurred, knew anything had happened.

Race Well Handled

Aside from this there were no untoward accidents and no possibilities of any other than the usual risk when a score of cars are traveling at high speed. The race as a whole was very well handled, the track perfectly guarded, the timing seemed perfect, although the scoreboards and announcing were many laps behind the progress of the race. The scoreboards were the worst in this respect, being neither up to date nor always correct.

DePalma was not the only driver who had hard luck after a wonderful showing. Wilcox with only one lap to go to finish in fourth place had to withdraw with a broken connecting-rod. Galvin very nearly had a similar experience, as his car went out while he was making an additional lap after he had been flagged in fourth, and had to push his car part way around the course.

Mulford, who was slated to drive a Duesenberg, did not appear at the starting line and Devore took his place. The Ben Hur, which was a local entry, and fathered by President Reid of the speedway, was not in shape to start. This was to have been driven by Louis Chevrolet. Rickenbacher's Maxwell was not in the best of shape when he started, and much credit is due him for jockeying it into third position.

Attendance Under 10,000

The attendance at the race is judged as below par. It is regretted that more than 8000 to 10,000 did not see the birth of this particular race, the Grand American. But if such another race as this of to-day is ever foreseen in the announcement of an event at the Chicago speedway, the fame of the performance to-day will guarantee a record-breaking gathering.

Everywhere were sportsmen and sportswomen. That is the impression the Grand American would probably give most general observers. Most of the crowd were automobilists, if the parking space can bear witness to it, for back of the stands cars were parked within touch of each other along practically the entire stretch there. Enterprising guardians at the entrance to the speedway reaped dollars for space in vacant fields nearby, vacant fields that were well filled by 2 o'clock. As usual the allotments infield showed many cars.

Resta's car was equipped with Silvertown tires, Miller carbureter, Bosch magneto, K L G plugs, R-W wheels, Levett pistons, and used Oilzum. Aitken's car used a Zenith carbureter, Goodyear tires, Bosch magneto, K L G plugs, R-W wheels, Levett pistons, and used Oilzum.

Above—Fig. 1—Diagram of the light cast by a good lamp, the direct rays from the bulb furnishing adequate illumination without glaring to eyes outside the limits inclosed by the heavy lines. Below—Fig. 2—Tilting the lamp downward so that the edge of the beam, instead of its center line, is parallel to the ground, eliminates glare

Eliminating Glare Is Easy

A Simple Language Explanation of What Causes Glare and How to Prevent It—What S. A. E. Is Doing To Assist Manufacture of Non-Glaring Lamps

By A. Ludlow Clayden
Chairman S. A. E. Standards Committee

GLARE from an automobile headlamp is caused by the concentrated rays in the beam of light striking the eye of the observer and preventing the lesser light from illuminated objects close to the lamp from affecting the eye strongly enough to give vision. A headlamp lights up objects on the road. An observer facing the lamp can see those objects as long as the reflected light reaching his eye is not overpowered by the light coming direct from the lamp.

Provided the direct light is kept out of the eyes of the observer, the stronger the light that the lamp casts on the road the better can the road be seen by the observer facing the lamp as well as by the driver of the car behind it.

Thus to make the night use of automobiles safe, it is as requisite to have enough light thrown on the road as it is to prevent too strong a light from being cast into the face of anyone on the road.

Arrangement Is Everything

A properly arranged lamp of great candlepower will be less disconcerting to anyone approaching it than will an improperly arranged one of small candlepower.

The light of a headlamp is a concentrated beam surrounded by a general spread of unconcentrated light. All that we need to do to eliminate glare is to keep that concentrated, central beam so directed that none of its rays reaches the eyes of a person in front of the lamp, the general spread of unconcentrated light will be helpful and not harmful.

This can be done very simply if the lamp is sufficiently well made. If the lamp is badly constructed it is impossible, not merely difficult but impossible in the fullest sense. Just why this is will be shown later.

Fig. 1 is a diagram of the light cast by a good lamp. The direct light from the bulb illuminates objects surrounding the lamp and close to it. The concentrated light does not touch the road for some distance, not till the beam has spread out. The edges of the concentrated beam are shown by heavy lines, and the center line of the beam by a dotted line. The lamp will not glare to anyone whose eye is outside the limits inclosed by the heavy lines.

With the lamp placed square to the car this means that a pedestrian will not notice any glare when the car is close to him, but he will notice it when the the man *B* is unable to see anything except the lamp and suffers extremely. This is because the upper edge of the beam is not as high as *A's* eyes but is higher than *B's*.

All we need to do then, is to so set the lamp, or so construct it that the upper edge of the beam cannot ever rise as high as a man's eyes however far away he may be.

Therefore, if we tilt the lamp downward as in Fig. 2, so that the edge of the beam is parallel to the ground instead of the center line of the beam, we have cured that lamp of glaring so far as any approaching pedestrian or driver is concerned.

This seems too absurdly simple to be true. It is true enough though *if* we have a lamp that really does give a beam with a sharp edge. The bulk of the trouble with headlamps is that they cast irregular beams and it is the purpose of the Society of Automobile Engineers to define limits for lamp manufacture that will make the beam sufficiently accurate to enable simple lamp adjustments to give the upper edge of the beam its proper position without uncertainty.

The lamps as made to-day are not reliable, because while any one lamp may be set to give the correct light distribution with one bulb, when the bulb is changed the light may alter altogether. This is because the position of the beam changes as the filament of the lamp is moved.

Fig. 3 shows the same lamp with the same setting and the sort of light it will give when the bulb is moved so as to put the filament into different positions. At *A* we have the right spread of light. At *B* the filament is too far forward and at *C* it is too far back, the result in either case being to widen the beam so that it is no longer within safe limits; thus converting a non-glaring lamp into one which will glare very badly. If the filament is truly in the central axis of the bulb we can cure this by focussing.

The average man is so helpless when it comes to focussing that he would be better off almost without any focussing device whatever, for he then would not maladjust a good lamp which he is likely to do if the chance is given him.

By adding to the cost of manufacture of bulbs a little they can be produced so that adjustment is not necessary. So that any bulb will go in any one reflector and give the same sort

of light as its predecessor. This means that one reflector or focussing adjustment would last the life of the lamp.

Next comes the reflector itself. If this is pressed accurately to shape the beam of light will be true and handlable, but if the reflector is irregular, of one curvature at one place and another somewhere else, then the beam will throw out odd rays of glaring light. This means that limits of accuracy should be imposed upon reflectors.

Another thing about reflectors is the kind of curvature they have. If a reflector is very deep, then moving the filament of the lamp has less effect on the beam than when the reflector is shallow. Some of the reflectors in use to-day are so shallow that even an expert in a laboratory has difficulty in adjusting the bulb so as to get a proper beam. This means that if we hold the bulb tolerances down to say 1/64 in., the reflector should be deep enough so that a 1/64 in. variation of filament position makes no difference to the light. With a bulb held to tolerances, and a reflector held similarly we can be certain that a lamp once set properly will remain set properly.

So much for keeping down glare. There is something else just as important, however, and this is to insure enough light for driving that will be safe to the car carrying the lamp as well as to other road users. This means that the car must throw a light far enough ahead to make clear any objects on the road within not less than 200 ft. and that the sideways spread of the beam must be enough to illuminate objects at the sides of the road. The man meeting the car wants to see where he is walking just as much as the driver wants to see where he is steering.

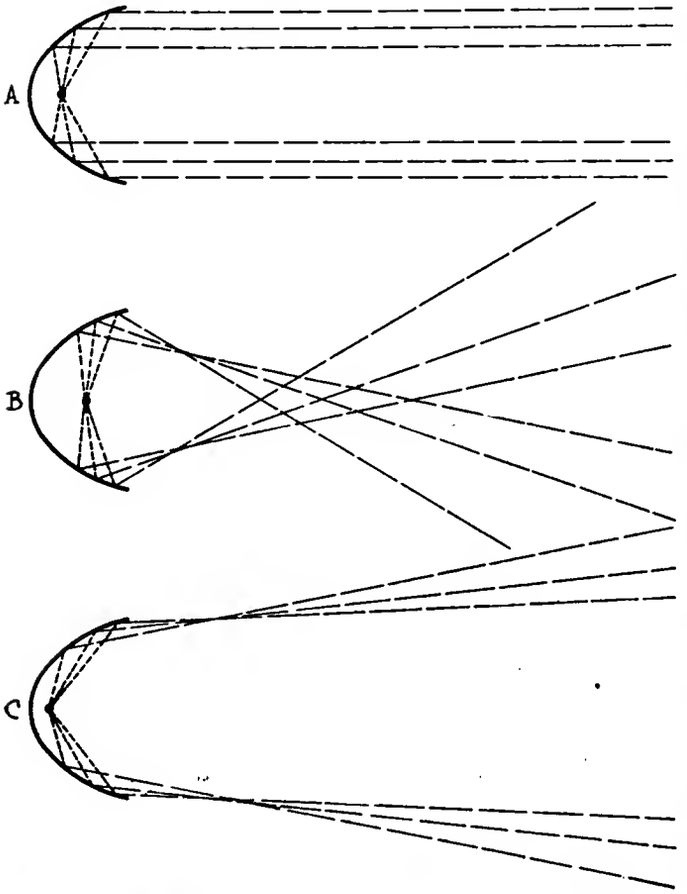

Fig. 3—The same lamp as considered in Figs. 1 and 2 with the same setting and the light it will give when the bulb is moved so as to put the filament in a different position

Adequate Light Required

This means that in making any regulation about lighting it is essential to specify enough light as well as to specify the direction of that light. The idea that glare could be cured by abolishing lamps is good enough as far as it goes, but it would merely substitute worse dangers for present ones.

Herein we find an objection to the simple method of directing light by tilting the lamp, for a tilted lamp will need to be intrinsically more powerful than an untilted one if we are to get the same *desirable* light on the road. Why this is is very easily seen from Fig. 4. This is an exaggerated diagram of the effect of tilting. With the parallel set lamp the beam strikes the road a long way ahead, when we tilt the lamp it hits the ground soon, and after the beam has hit the ground it is used up, it is no longer of much use. The middle of the beam is its brightest part, so we want to have the middle line hit the road as far ahead as we can.

Suppose we want to have it hit the road 200 ft. away and are compelled to tilt the lamp so that it strikes the ground at 150 ft., then to get the same light on the road we must increase the brilliancy so that the ray which does strike the road at 200 ft. with the tilted lamp is as bright as the middle ray of the untilted one. There are ways of overcoming this, but most of them are patented at present. So the simple thing to do is to put up with the loss of efficiency and leave it to the manufacturers to work it out for themselves.

The electrical equipment division feels that by specifying the proper tolerances for bulb manufacture and by specifying those for reflector construction, they can insure the production of lamps that only require to be tilted in order to be non-glaring. The following is an ideal of illumination to insure safety both by the provision of enough light to show the road and things upon it, and to prevent glare:

"A headlamp of an automobile will give an adequate light combined with elimination of glare when:

"1. The light is sufficient to reveal any person, vehicle or substantial object on the road straight ahead at a distance of 150 ft.

"2. There is sufficient side illumination to reveal any person, vehicle or substantial object 10 ft. ahead of and 10 ft. to one side of the lamp.

"3. The headlamp is so arranged that no portion of the reflected beam of light, when measured 75 ft. or more than 75 ft. ahead of the lamp shall rise above 42 in. above the level surface on which the vehicle stands."

This is the ideal, and it is attainable by limiting the tolerances in bulb manufacture, limiting the form and the degree of inaccuracy of the reflector and, finally, by tilting the lamp.

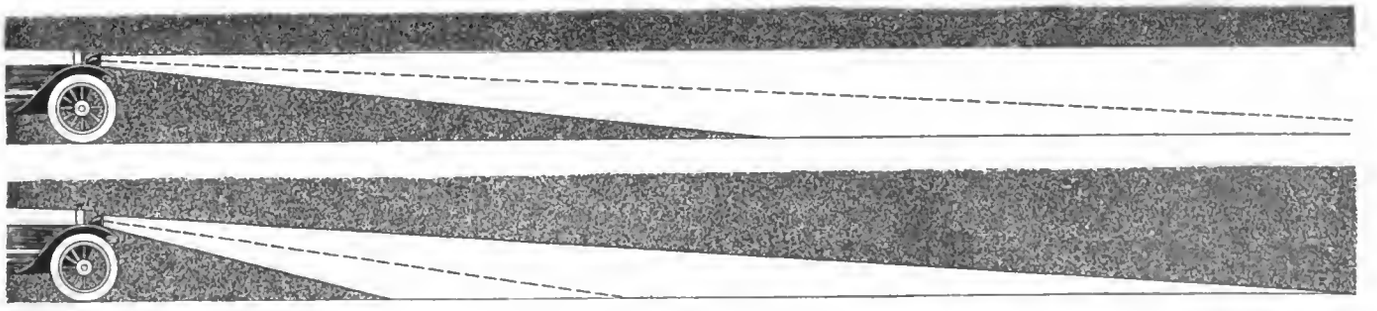

Fig. 4—An exaggerated diagram from the effect of tilting the lamp so that its rays hit the ground too soon

The Rostrum

Finding Differential Gear Ratio

EDITOR THE AUTOMOBILE:—Kindly advise how to find the gear ratio of a differential without disassembling. A Chalmers 6-30 is geared to 5 to 1 on direct. What would be the correct way of ascertaining this ratio without disassembling? If I jack up one rear wheel and put transmission in direct or high, then turn the motor by crank one revolution, and the jacked wheel only turns half way around, why do they say the engine turns one to the rear wheel's five times? Please explain.

West Chester, Pa. W. H. W.

—The gear ratio of 5 to 1 means 5 revolutions of the engine to one of the road wheels. When the differential is operating as it must be with one wheel stationary on the ground and the other turning then the rear axle ratio will only be half what it is when both wheels are turning. If your rear axle ratio is 5 to 1 you will find that with one wheel jacked up it requires 2½ turns of the engine to give you one full turn of the back wheel.

A better way is to turn the back wheel and count the number of turns made by the propeller shaft. You can usually do this by watching the universal joint. Mutiply this number of turns by two and you will have the two ratios.

Engine Needs Thorough Overhauling

Editor THE AUTOMOBILE:—I drive a 1911 Reo that has been run about 16,000 miles and seems to give as good service now as when it was new, with one exception. The third and fourth cylinders pump oil, the fourth one being the worst, so that I have to clean the spark plugs and scrape out the cylinders every 80 to 100 miles, else the engine will develop a very perceptible knock when pulling up grade.

The compression seems as good as when the car was new, but the third cylinder never did have as good compression as the other three. The fourth cylinder has good compression though it is very bad about pumping oil and fouling spark plug, and so far as I can tell, it is the cylinder that produces the knock.

Will you kindly tell me how to remedy this? Would a new set of cylinder rings do the work, and if so, what kind would be best suited for the Reo engine?

Browning, Mo. J. P. B.

—Probably your engine requires a thorough overhauling. If you cannot get equal compression in each cylinder by grinding the valves it will be necessary to examine the pistons and piston rings and also to measure the cylinders to see whether the latter have worn oval shape. If they are out of round it will be necessary to have them reground to fit oversize pistons with new piston rings. If the cylinders are perfectly round the trouble might be reduced by fitting one or two of the special rings of which there are now so many on the market.

The trouble could also be caused by dirt in the oiling system. Make sure that this is quite clean, especially that the oil returns from the crankcase to the oil reservoir are not clogged. You should wash out the whole crankcase very thoroughly with kerosene.

If you find the pistons and cylinders in perfect condition, have the lubricating system absolutely clean and still have not entirely cured your trouble, you could file the dips on the lower ends of the connecting-rods so that while they will still dip into the oil as deeply as before their lesser width will prevent so large a quantity being splashed.

Lubrication Is Provided on Grades

Editor THE AUTOMOBILE:—I have a 1916 Studebaker six-cylinder car which is lubricated by a circulating splash system. A gear pump draws the oil from the rear of the crankcase. If the oil is allowed to become a little low it will not cover the suction end of the pipe when descending steep grades. How long will the supply in the splashed troughs lubricate the engine when the pump is not feeding?

2—When there is a full supply of oil in the crankcase, it is said that there is too much lubrication in the end cylinders. Is it possible for the oil to rise so high at the ends of the crankcase that it will cover either No. 1 or No. 6 splasher troughs on grades? If not, how could a full supply cause excessive lubrication?

Denver, Col. C. E. R.

—Considering that when descending steep grades the engine is not delivering any power there is no need to worry about the condition of the oil. There will be plenty of oil throughout the engine to keep it lubricated for the longest descent.

2—It is practically impossible to design an engine for splash lubrication which will not load the end of the crankcase when the engine is tilted through a large angle. Actually to cover the splasher troughs would require a degree of tilt equivalent to an extremely steep hill.

Continental Engine in 1917 Overland

Editor THE AUTOMOBILE:—Kindly advise me whether the engine in the 1917 Overland six is made by the Continental Motor Co. The model is No. 85-6 and sells for $925.

Franklin, N. J. F. C. H.

—The Willys-Overland Co. will continue to use the Continental engine for its six-cylinder car throughout 1917.

Changing Hudson 33 Into Delivery Car

Editor THE AUTOMOBILE:—I have a 1911 Hudson 33 torpedo body five-passenger car which I wish to change into a commercial body to use for delivery of farm produce. Is there any body made to fit these conditions? The gasoline tank would have to be relocated as it is now under the front seat.

Mansfield, Mass. S. F. F.

—You would have to take this matter up with a carriage builder. There is no stock body made which would suit you. You must be very careful that you do not overload the chassis since the frame, springs and axle are only designed to sustain the weight of five passengers and any dead load which you put on it ought not to be greater than that.

Assuming you convert the body, the useful load it would carry in addition to the driver ought to be limited to 600 lb.

There is no reason why you should not continue to keep the

gasoline tank under the driver's seat. Our advice is that you discuss the matter with someone near you who you think could build a body and get his ideas on it. The usual way to get a reasonable platform space is to build wooden cross pieces which will lift the platform about 1 ft. above the top of the wheel. Possibly you could move the driver's seat forward by setting the steering gear more nearly vertical but it is very likely the position of the gear lever and of the pedals will prevent you gaining much in this way. Probably the cheapest plan would be to leave the front seat as it is and substitute a small platform for the tonneau.

Information on Nitrogen Filled Bulbs

Editor THE AUTOMOBILE:—Do nitrogen-filled bulbs give more light than regular vacuum type with the same amount of feed from battery?

2—What would be proper candlepower nitrogen bulbs to substitute for regular vacuum type 15 cp. bulbs in headlight, would it be 21 cp.?

3—What would be the approximate added burden to 6-volt battery regularly using 15 cp. vacuum type headlights to substitute 36 cp. nitrogen bulbs, the regular vacuum type consuming 2½ amp. and the 36 cp. nitrogen bulbs consuming 4 amp.?

4—Using regular vacuum type 15 cp. bulbs of 2 amp. generator shows battery charge at about 15 m.p.h. when headlights are turned on. At about what speed would battery charge using 36 cp. nitrogen bulbs of 4 amp.?

5—Does a 21 cp. nitrogen bulb, actually give 6 more candlepower than a 15 cp. regular vacuum bulb when each bulb uses 2½ amp.?

Peebles, Ohio. A. C. P.

—Yes.

2—Yes.

3—The addition would be the difference between the current drawn by the small bulb and that needed for the large one.

4—It is not possible to answer this without knowing the exact characteristic curve for the generator.

5—It ought to do so.

Fitting Route Indicator to Speedometer

Editor THE AUTOMOBILE:—I am interested in connecting a route indicator to the Warner speedometer with which my 1916 Cadillac eight is equipped, and I am at a loss how to determine the exact speed of the shaft at the point where it it connects with the speedometer.

2—The closest I can come to it is 690 r.p.m. I am advised by the Stewart people that the speed of the shaft on their old model speedometer was 2523 r.p.m., and on their 1912 model was 1009; but they failed to give me the speed of the later models.

Occoquan, Va. G. A. D.

—The speedometer shaft on your car should turn 680 times in a mile in order to register mileage correctly. It will do this if the car is equipped with standard size tires 36 by 4½ in.

2—When speedometer shaft speeds are given in the revolutions per minute this usually means revolution per minute at some particular number of miles per hour.

Oil Satisfactory in Ford Cups

Editor THE AUTOMOBILE:—Kindly advise me if it is desirable to substitute grease cups for the present oil cups on a Ford car and if they are as satisfactory as concerns lubrication as the oil cups?

2—Where can I secure grease cups for the Ford to replace the oil cups having a large grease capacity? Also cups having a large oil capacity to replace the present system?

3—Is there any power pump that has proven successful on the Ford? What are the merits of the spark plug pumps? I have heard that they are detrimental to the engine.

Hot Springs, Va. R. B. D.

—As long as you keep the oil cups filled lubrication will be just as good as you will get with grease. Many engineers greatly prefer oil to grease, as it flows much more easily in cold weather.

2—You could get greasecups or large oil cups from any good accessory house or your dealer could obtain them for you.

3—Any of several tire pumps will give you satisfaction. The spark plug pumps are very good and cannot possibly damage the engine. If you purchase one of these pumps do not forget that it is most effective when the engine is running slowly. If the engine is speeded up too much the piston in the pump will not draw in a full charge as it does not get time to make its return stroke.

55,000 Wire Wheel Cars in 1916

Editor THE AUTOMOBILE:—Kindly advise the probable number of automobiles equipped with wire wheels during the 1916 season and also the probable number of cars to be equipped with wire wheels in the 1917 season.

Johnstown, Pa. F. H. M.

—At the present time we estimate that about 55,000 new cars have been equipped with wire wheels in 1916 and the manufacturers expect that fully 200,000 will use them in 1917.

Bijur Regulator Wiring Diagram

Editor THE AUTOMOBILE:—Will you kindly give me a wiring diagram of a Bijur regulator, showing how same is connected to a 1913 Packard car generator, replacing the mercury regulator made by the Delco company.

2—Also give a diagram showing the internal circuits of same and any other data you may have explaining its operation.

New York City. B. F. K.

—Fig. 1 shows the connections to a Bijur regulator. Regarding the internal mechanism, this Bijur regulator is a vibrating field voltage controller described on page 741 of THE AUTOMOBILE for Oct. 21, 1915. The diagram of the vibrating type regulator published herewith shows all the essential details of the Bijur instrument.

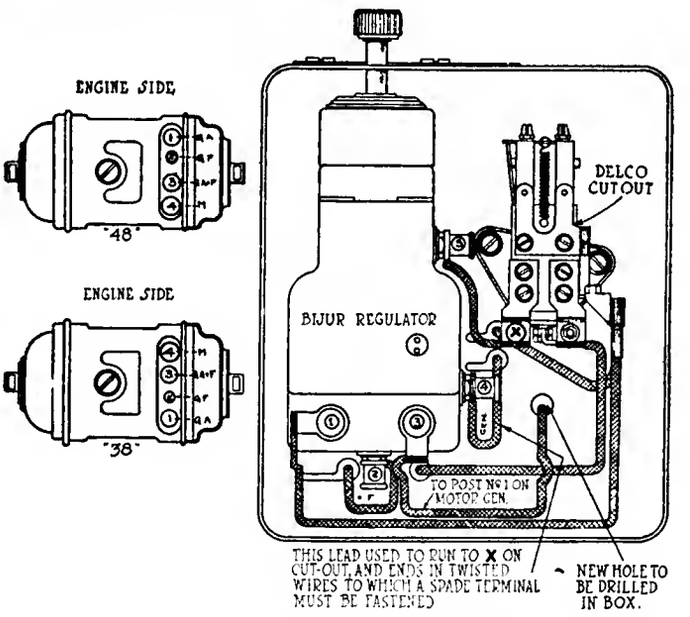

Fig. 1—Wiring diagram of a Bijur regulator, showing connections as used on a 1913 Packard generator

ACCESSORIES

Hercules Auxiliary Bearing

THESE bearings are designed to increase the carrying capacity of Ford cars and to prevent the breakage of axle shafts. The bearings remove the weight of the car and load from the axle shafts and permit the use of solid rubber tires or demountable rims by taking care of the extra weight. The manufacturer states that these bearings also eliminate wobbling of the wheels and side sway. A set consists of two combined radial and thrust bearings capable of carrying a load of 3800 lb. at axle speed. These bearings are mounted on the outer ends of the Ford rear axle housing and engage steel brackets to be fitted in the inside of the brake drums. These brackets are secured by six special bolts, replacing the bolts used for fastening the brake drums and hub flanges to the wheels. When the wheels are in place on the axle shafts, these steel brackets engage the outer race of each auxiliary bearing, bringing these bearings only 1¼ in. from the center of the wheel. Thus they carry the load close to and on the wheels. The bearings can be installed by anyone with a wrench, no machine work or change in the Ford wheels or axles being required. —Hercules Auxiliary Bearings Works, 327 S. La Salle Street, Chicago, Ill.

Superior Spot Lamp

Combining the functions of a spot and trouble light this lamp can be moved in any direction desired and throws a direct beam of light far in advance of the car. It has a silver-plated spun brass reflector and the exterior is finished in dark enamel which the manufacturer states will not peel. The lamp is fitted with an adjustable, removable mirror at the back of the clamp so that the driver can see cars coming up behind. The lamp itself is a 6 volt 21 candlepower nitrogen type with double contact, the switch being on the end of the handle. The windshield attachment is of heavy steel with strong bolts to prevent the lamp from sliding. The lamp is 6¼ in. in diameter over all and the length from the switch to the lens is 7⅞ in. A cord 10 ft. in length is supplied with each lamp for use as a trouble detector. — Pittsburgh Lamp, Brass and Glass Co., Pittsburgh, Pa.

M. and M. rim contractor

M. & M. Rim Contractor

A tool for removing or replacing rims of the Standweld, Baker, Firestone, Detroit or Kelsey type. Clamps connected by a threaded rod are fastened on opposite sides of the rim, and the rim contracted by means of a turnbuckle. Turning the buckle in the opposite direction expands the rim to its original position. Price, $1.—M. & M. Mfg. Co., Bayside, N. Y.

The York Gas Saver

An auxiliary air valve screwed into the intake manifold. It consists of a metal nipple carrying an adjustable nozzle whereby the amount of additional air entering the manifold may be regulated. The installation requires the drilling of a 11/32 in. hole in the intake manifold just below the spread, tapping it to ⅛ in. std., and screwing in the valve. Price, $3.—York Gas Saver Co., 1518 Jefferson Avenue, East, Detroit, Mich.

Name-On Robe

The owner's name is interwoven in the edge of the robe. It is made of long fiber mohair and bound with triple-stitched felt. The robe is reversible, having one color on one side and the other color on the reverse. The name is woven so as to show on both sides. The robe is claimed to be durable and warm without being bulky or heavy. Price, 54 by 72 in., $12.50; 54 by 84 in., $15.—J. & E. Dawson, Palethorp and Somerset Streets, Philadelphia, Pa.

Standards Committee Accepts Four S. A. E. Reports

(*Continued from page* 645)

width of the V is to be 3 mm. and its length 2.5 mm., as illustrated.

Location of Filament in Bulb—7—All headlamp bulbs regardless of their diameter are to bave the center of the filament located in the axis of the bulb, 1¼ in. from a plane tangent to the nearer sides of the locating pins in the bulb base, as in the sketcb.

Location of Receptacle in Headlamp—8—All headlamp receptacles are to be located in the reflectors so that a plane passing through the registering points of the bayonet slots is 1¼ in. from the focal point of the reflector when the receptacle is at the mid-point of its adjustment, as illustrated.

Focal Length of Reflector—9—It is tentatively recommended that all headlamp reflectors be made as near as possible to the outline of a true parabola of 1¼ in. focal length, as in the drawing.

Limits on Location of Filaments—10—Investigation is being carried on in regard to the practicability of locating filaments within limits close enough to avoid the necessity of adjustments for focusing, or at least of focusing in replacing bulbs.

11—At the present time, filaments are located in the glass portion of the bulb by eye, and the glass bulb is afterward cemented into the base, its exact position being dependent upon variation in the size of the bulb.

12—Under these conditions it is said that the total variation is held within limits of 1/16 in. plus or minus. One of the largest manufacturers of bulbs has reported that the cost of bulbs would be increased by from 5 to 10 cents each by changes in manufacturing methods which would hold the center of the filaments within 1/64 in. of the bulb axis and within 1/32 in. (plus or minus) of the standard distance from the pins in the base.

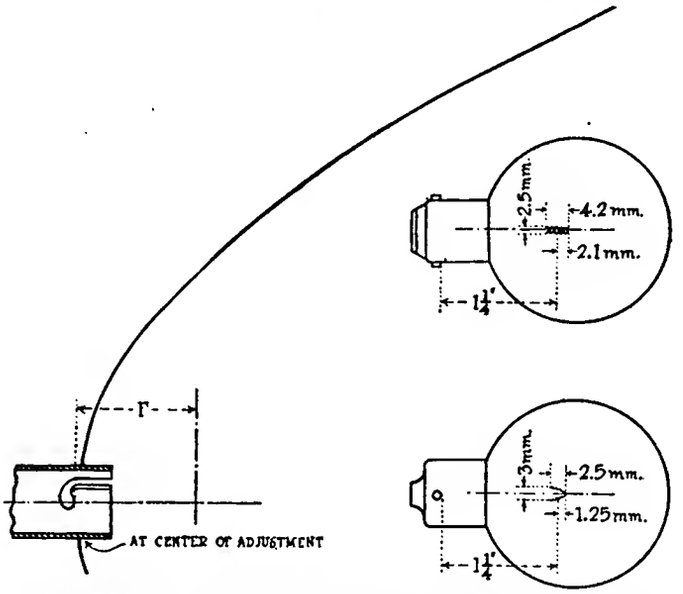
Mounting of Starters, Generators and Ignition Distributers—13—The sub-division on standards for mounting these various electrical units has been doing active work, but is not yet prepared to offer final recommendations. Definite proposals for mounting starting motors and generators have been proposed and criticized. Members of the sub-division are engaged in trying out the proposals on layouts of engines of different make, in order to revise the proposals so as to make them suitable to existing engine designs as far as possible. It is hoped that this work will be completed before the end of the present calendar year.

14—Standard dimensions for ignition distributers have been formulated with the co-operation of interested manufacturers. The dimensions are suitable for mounting the distributer either on the engine or on the generator. The proposal has not yet been submitted to the division.

Storage Battery Subjects—15—A sub-division has been appointed and has done some preliminary work in regard to terminals of storage batteries for gasoline cars. Another subject which this sub-division will consider is dimensions for storage battery compartments.

Among the speakers were A. G. Batchelder, Dr. H. M. Rowe and J. O. Lagorz of the American Automobile Assn. W. E. McKechnie, electrical engineer, Cadillac Motor Car Co., stated that the research of the headlight glare sub-division showed that the problem was very complicated and that no solution could be reached until scientific study revealed certain causes of glare not now known. To this end he proposed that a separate division be created to consist of a few members deeply versed in the subject to co-operate with other engineering bodies in the electrical and illuminating field in collaboratively solving the question. This proposal was enthusiastically received in view of the imminence of much drastic legislation at great variation pending in different states.

The problem first encountered by the sub-division was the variation in filament position on different bulbs which destroyed the focus and caused stray and reflected lights. It is working now to standardize filament position and shape but more research is needed, especially in determining correct focal length for ample illumination without glare and provision for tolerance in filament placing without manual adjustment. Mr. Rowe also supported the suggestion in telling the committee sometbing of the existing legal situation.



Left—Sectional plan diagram of headlamp reflector and receptacle. F is focal length of reflector—1¼ in. Right—Location of filaments in bulbs. Above—Vacuum bulb. Below—Gas filled bulb

Truck Standards

Discussion of military truck standards followed the report of the truck control standards chairman, H. D. Church, Packard Motor Car Co. All the recommendations were approved with the understanding that the standards did not mean to require any segment for spark throttle levers being recognized as advantageous in commercial work and imperative in military application. The report follows:

Truck Control Standards

1—The following recommendations apply to both right and left drive trucks:

Gearshift and Hand Brake Levers—2—It is recommended that the gearshift and hand brake levers be placed at the driver's right, with the hand brake lever to the right of the gearshift lever. The band brake lever is to be pulled back for brake application. The gearshift lever is to be fitted with a latch guarding the reverse position, or the equivalent of a latch, when used with either a three or four-speed transmission.

Gearshift Lever Handle Positions—3—It is recommended that for three-speed transmissions the positions of the gearshift lever handle be the same as recommended by the miscellaneous division for standardization for pleasure cars. Four-speed transmissions are to have the forward speeds so arranged that the gearshift bandle in high speed is in the same position as with the three-speed transmission, low speed occupying the place of reverse. The location of the reverse position is to be left optional. It is further recommended that with either three-speed or four-speed transmissions, the various speeds be clearly indicated, either on the gate or at the base of the gearshift lever.

Clutch and Brake Pedal—4—It is recommended that the clutch pedal be located to the left of and the foot brake pedal to the right of the fore and aft center line of steering column.

Accelerator Pedal—5—It is recommended that the accelerator pedal be placed to the right of the brake pedal.

Spark and Throttle Hand-Levers—6—It is recommended that spark and throttle hand-levers, if used, should be located to the right of the fore and aft center of the steering column. The spark lever should be the shorter of the two and both levers carried on stationary sectors. Both levers should be arranged so that they are pushed forward to advance the spark and to open tbe throttle.

Military Specifications Mangled

The tentative military truck specifications were literally torn to shreds as to detail, Henry Souther maintaining stand-

(*Continued on page* 681)

Details of Argentine Trade-Mark Law—Part II

(*Continued from page* 646)

themselves aggrieved by the mark may file opposition, and the applicant's attorney is notified and given an opportunity to reply. If the opposition is based on a previous registry or is not merely capricious, the Office cannot decide the case, and the proceedings are suspended. Applicant may then ask for the case to be sent to the Federal Courts, where the proceedings take the nature of an ordinary lawsuit.

Renewals: At the end of the 10 years period the registration may be renewed for an equal period, and so on indefinitely. The proceedings are exactly the same as in the original application. The term begins as from the date of grant, although the mark is protected as against subsequent applications from the moment when it is filed.

Secret manner of printing: Applicant may keep secret the manner of printing the mark in certain cases. In such cases the process of printing must be fully described and the description filed together with the application, in a sealed envelope, which may only be opened in open court in case of litigation.

Infringement: All infringement cases are tried in the Federal Courts. The penalty (see previous clause on this subject) consists of a fine of $20 to $500 Argentine and arrest from 1 month to 1 year, not redeemable by payment of money. The goods sold under a mark declared by the court to be an infringement are confiscated and sold for the benefit of the school fund. The sentence of the Federal Court may be carried to the Federal Chamber of Appeals and the winner of the suit may then sue the loser for damages in the common courts, if so declared in the sentence.

Administration: The author would be lacking in gratitude for courteous treatment experienced from the entire staff of the Argentine Patent and Trade Mark Office during many years, if he failed to close this article without a word of commendation for them. Above all he desires to state his sincere conviction that this department is carried on in a spirit of fairness and justice, interpreting the law in so far as it lies within its province to do so, in an able and strictly impartial manner. Although it may seem to some applicants that their cases are unduly delayed, this is entirely due to the great increase in the number of applications without the corresponding increase in staff.

There are twenty-five different classifications for copyright consideration, those quoted below apply to the automobile industry:

Class 12.—Machines, apparatus and elements of transport in general, their various parts and their accessories.

Such as: Locomotives, rolling stock for railways and tramways, telpherage systems, rails, semaphores, cranes and winches, movable bridges, endless carriers, lifts or elevators, freight elevators, endless screws, automobiles, aeroplanes, airships, balloons, motorcycles, bicycles, carts and carriages in general, hydroplanes, ships, motor launches, boats, dredges, floating cranes.

Class 17.—Caoutchouc, rubber and guttapercha, wrought and unwrought and in every state of preparation, and all articles made of that substance, except those used in electricity, surgery or orthopædia.

Such as: Transmission belts, air chambers and covers for vehicle tires, balls and toys, tubes, plate, cord, etc.

Class 19.—Leather furs and skins, wrought and unwrought, not included in other classes. Saddlery and harness, trunks, and traveling goods generally.

Such as: Fur garments, harnesses, trappings, horse furnishings, whips, blankets for animals, buckles, stirrups, bits, spurs, reins, trunks and valises in general, straps, portmanteaux, walking stick cases, hat cases.

Class 20.—Electricity, electrical machinery, supplies, apparatus and accessories for the production of power, heat and light, telephony, telegraphy and wireless telegraphy.

Such as: Dynamos, alternators, resistances, magnetos, telegraphic, telephonic and radiographic apparatus, electric lamps in general; sockets, tulips and globes, motors, commutators, wire and cable for electrical use, transformers, carbons for electric lamps, insulators, voltmeters, ammeters and other measuring and experimental apparatus; insulating fabrics, accumulators, batteries and cells.

Class 14.—Apparatus and articles for heating; ventilation, illumination, refrigeration, hydrotherapy, sanitary articles, machines, apparatus and supplies for cleaning, in general, washing, soaking and cleaning clothes.

Such as: Ranges, braziers, heating devices, stoves, central heating boilers, radiators, thermo-syphons, still worms, ventilators, aspirators, air injectors, gas generators, lamps of all kinds, lighting devices, luminous buoys, chandeliers, lanterns (of all kinds), freezing machines, machines for making ice and ice creams, refrigerators, shower bath apparatus, douches, baths of all kinds, bath-tubs, lavatories, water-closets, bidets, syphons, traps and other sanitary articles, machines, apparatus and articles for washing, wringing, ironing, and drying; carpet, curtain and tapestry cleaners, vacuum cleaners, brooms, feather dusters, brushes, mops, polishing cloths and skins; metal, wood, clothes, and leather cleaning soaps, pomades, powders and liquids; starch, borax, soda, bluing, preparations for polishing and waxing floors, stain erasers, etc.

Class 15.—Fabrics and textures in general; knitted fabrics; table linen, and linens in general.

Such as: Wool, silk, linen, cotton, jute and other vegetable fiber cloths and fabrics, waterproof or not; mixtures of the same; knitted goods, stockings, undershirts, underwear made of these fabrics; table cloths and napkins, sheets, pillow cases, quilts and blankets.

Class 10.—Hardware, cutlery, paints and colors, locksmithery, ironmongery, builders' hardware, house furnishing, bazaar articles and tinmongery; non-electric cable, canvas goods; picture frames and moldings; basketware, etc.

Such as: Tools in general with or without edge or point, not otherwise classified; razors and safety razors; cutlasses; knives, forks and spoons; daggers, colors and paints; varnishes, sealing wax, lacquers, wall paper, brushes, oil and turpentine for paints, rope, twine, and cord of hair or fiber, locks, bolts, hinges, chains, anchors, articles of ironmongery, of tin, brass, and the like; kitchen utensils, iron glazed and enamel ware, nails and screws, tents, flags, canvas awnings, sails, bags of any kind of cloth for any purposes; insulating cloths and papers; damp-proof materials; bottle caps, corks and metallic stoppers, fire kindlers, night tapers, baskets and similar objects in general; chains of all kinds, transmission belts in general; except those of caoutchouc or rubber.

Class 5.—Machines and apparatus of every kind of industry not otherwise classified, parts of the same; accessories and implements for dyeing or filtering. Machines, apparatus and implements of agriculture, aviculture, apiculture, fish culture, dairy, grape, wine culture, forestry, and cooperage.

Such as: Pumps, generators for motors, machines driven by water, gas, naphtha, steam and the like, machine ing machines and needles for same; fire tools, boilers not otherwise classified; motors, sewing, knitting and embroider- extinguishing engines, pumps and apparatus, etc.

Doehler Moves Brass Dept.

BROOKLYN, N. Y., Oct. 16—The Doehler Die Casting Co. has removed its brass-back bearing department from Brooklyn to its new Toledo, Ohio, plant.

Accessory Spaces Allotted to 87 Concerns

(*Continued from page 642*)

Goods Co.; Lumen Bearing Co.; Parry Mfg. Co.; Wagner-Hoyt Electric Co.; West Side Foundry Co.; Rubber Insulated Metals Corp.; and the Syracuse Malleable Iron Works.

The list of exhibitors follows:

NEW YORK AND CHICAGO

A. B. C. Starter Co.....Detroit, Mich.
American Bronze Co.....Berwyn, Pa.
American Hardware Corp. (Corbin Screw Corp. Division).....New Britain, Conn.
Au-To Compressor Co.....Wilmington, Ohio
Automobile Supply Mfg. Co..Brooklyn, N. Y.
Benford Mfg. Co.....Mt. Vernon, N. Y.
Brown-Lipe Chapin Co.....Syracuse, N. Y.
Brown-Lipe Gear Co.....Syracuse, N. Y.
Brunner Mfg. Co.....Utica, N. Y.
Buda Co.....Harvey, Ill.
Byrne-Kingston & Co.....Kokomo, Ind.
Carr Co., F. S.....Boston, Mass.
Celfor Tool Co.....Buchanan, Mich.
Champion Ignition Co.....Flint, Mich.
Corning Glass Works.....Corning, N. Y.
Cowles & Co., C.....New Haven, Conn.
Corcoran-Victor Co.....Cincinnati, Ohio
Cramp & Sons Ship & Engine Building Co., Wm.....Philadelphia, Pa.
Dann Products Co.....Chicago, Ill.
Detroit Weatherproof Body Co.....
Dixon Crucible Co., Joseph..Jersey City, N. J.
Doehler Die Casting Co.....Brooklyn, N. Y.
Dyneto Electric Co.....Syracuse, N. Y.
E. A. Laboratories Co., Inc...Brooklyn, N. Y.
Eclipse Machine Co.....Elmira, N. Y.
Electric Storage Battery Co., Philadelphia, Pa.
Evapco Mfg. Co.....Detroit, Mich.
Ferro Machine & Fdry. Co..Cleveland, Ohio
Findelsen & Kropf Mfg. Co.....Chicago, Ill.
Gabriel Mfg. Co.....Cleveland, Ohio
Gemco Mfg. Co.....Milwaukee, Wis.
General Electric Co.....Schenectady, N. Y.
Globe Machine & Stamp. Co..Cleveland, Ohio
Gould Storage Battery Co....New York City
Gray & Davis.....Boston, Mass.
Halladay Co., L. P.....Streator, Ill.
Hall-Thompson Co.....Hartford, Conn.
Hartford, Inc., Edward V..Jersey City, N. J.
Hassler, Robert H.....Indianapolis, Ind.
Hayes Mfg. Co.....Detroit, Mich.
Hayes Wheel Co.....Jackson, Mich.
Heinze Co., John O.....Springfield, Ohio
Heinze Electric Co.....Lowell, Mass.
Kellogg Mfg. Co.....Rochester, N. Y.
Kent Mfg. Wks., Atwater...Philadelphia, Pa.
Klaxon Co.....Newark, N. J.
Kokomo Electric Co.....Kokomo, Ind.
Leather Tire Goods Co..Niagara Falls, N. Y.
Leece-Neville Co.....Cleveland, Ohio
Lipman Air Appliance Co.....Beloit, Wis.
Lumen Bearing Co.....Buffalo, N. Y.
Mann Co., F. W.....Milford, Mass.
Master Carbureter Corp.....Detroit, Mich.
Mosler & Co., A. R.....Mt. Vernon, N. Y.
Motometer Co.....Long Island City, N. Y.
New York Coil Co.....New York City
North East Electric Co.....Rochester, N. Y.
Otis Elevator Co.....New York, N. Y.
Pantasote Co.....New York, N. Y.
Parry Mfg. Co.....Indianapolis, Ind.
Perfection Spring Co.....Cleveland, Ohio
Piel Co., The G.....Long Island City, N. Y.
Pest-O-Lite Co.....Indianapolis, Ind.
Royal Equipment Co.....Bridgeport, Conn.
Sager Co., J. H.....Rochester, N. Y.
Schrader's Son, Inc., A.....Brooklyn, N. Y.
Shakespeare Co.....Kalamazoo, Mich.
Shaler Co., C. A.....Waupin, Wis.
Sparks-Withington Co.....Jackson, Mich
Splitdorf Electrical Co.....Newark, N. J.
Springfield Body Co.....Springfield, Mass.
Standard Thermometer Co.....Boston, Mass.
Standard Welding Co.....Cleveland, Ohio
Stewart Warner Speedometer Corp., Chicago, Ill.
Stromberg Motor Devices Co....Chicago, Ill.
U. S. Light & Heat Corp., Niagara Falls, N. Y.
Universal Shock Eliminator, Inc...New York
Vacuum Oil Co.....New York, N. Y.
Van Sicklen Co.....Elgin, Ill.
Veeder Mfg. Co.....Hartford, Conn.
Voorhees Rubber Mfg. Co..Jersey City, N. J.
Wagner-Hoyt Electric Co...New York, N. Y.
Waltham Watch Co.....Waltham, Mass.
Westinghouse Elec. & Mfg. Co. Pittsburgh, Pa.
West Side Fdry. Co.....Troy, N. Y.
Wheeler-Schebler Carbureter Co., Inc., Indianapolis, Ind.
Willard Storage Battery Co...Cleveland, Ohio

NEW YORK ONLY

Blackledge Mfg. Co., J. W.....Chicago, Ill.
Bosch Magneto Co.....New York, N. Y.
Breeze Carbureter Co.....Newark, N. J.
Budd Mfg. Co., Edward G..Philadelphia, Pa.
English & Mersick Co.....New Haven, Conn
General Bakelite Co.....New York, N. Y.
Hale & Kilburn Co.....Philadelphia, Pa.
Hartford Machine Screw Co..Hartford, Conn.
Herz & Co.....New York, N. Y.
Janney-Steinmetz & Co....Philadelphia, Pa.
Light Mfg. & Fdry. Co.....Pottstown, Pa.
Morse Chain Co.....Ithaca, N. Y.
Rubber Insulated Metals Corp., Plainfield, N. J.
Syracuse Malleable Iron Wks., Syracuse, N. Y.
Ward Leonard Elec. Co....Mt. Vernon, N. Y.
Zenith Carbureter Co.....Detroit, Mich.

CHICAGO ONLY

Badger Brass Mfg. Co.....Kenosha, Wis.
Continental Motors Co.....Detroit, Mich.
Edison Storage Battery Co.....Orange, N. J.
Garford Mfg. Co.....Elyria, Ohio
Imperial Brass Mfg. Co.....Chicago, Ill.
Oakes Co.....Indianapolis, Ind.
Remy Electric Co.....Anderson, Ind.
Simms Magneto Co.....East Orange, N. J.
Vesta Accumulator Co.....Chicago, Ill.
Warner Gear Co.....Muncie, Ind.
Waukesha Motor Co.....Waukesha, Wis.
Wilson & Co.....Chicago, Ill.

The complete list of exhibitors last year showed 306 accessory exhibitors at New York and 186 at Chicago.

Stiger Elected President

C. W. Stiger of the Stromberg Motor Devices Co., was yesterday appointed president of the Motor and Accessory Manufacturers, succeeding F. Hallett Lovell, who resigned. L. M. Bradley, prominent in the affairs of the N. A. A. M., and since connected with the automobile and accessory fields, has become manager of the association, succeeding W. M. Sweet, who has resigned to become the assistant to the president of the United Motors Corp. Mr. Sweet was yesterday elected a member of the board of directors to succeed Mr. Lovell and will serve until 1919. Mr. Sweet was also elected chairman of the 1917 banquet committee. Christian Girl of the Perfection Spring Co., was elected as a member of the board to succeed C. E. Whitney, resigned, His term will expire in 1919.

The association also voted to become a member of the Chamber of Commerce of the United States of America.

The following new members were admitted:

A-B-C Starter Co., Detroit, Mich., manufacturer of auto electric starting and lighting systems.

Celfor Tool Co., Buchanan, Mich., manufacturer of internal gear drive motor truck axles and high-speed drills.

Corning Glass Works, Corning, N. Y., manufacturer of technical glassware.

Detroit Weaterproof Body Co., Detroit, Mich., manufacturer of detachable closed tops.

Evapco Mfg. Co., Detroit, Mich., manufacturer of Evapco Gas Savers and Jiffy Starters.

Gillette Motors Co., Mishawaka, Ind., manufacturer of motors, manifolds, piston rings.

The Hall-Thompson Co., Hartford, Conn., manufacturer of polishes, dressings, enamels, chemical compounds.

Lipman Air Appliance Co., Beloit, Wis., manufacturer of air pumps, water and oil calculating pumps and other parts.

Morse Chain Co., Ithaca, N. Y., manufacturer of silent chain and sprocket wheels.

New York Coil Co., 338 Pearl Street, New York City, manufacturer of ignition devices, auto accessories.

Perlman Rim Corp., 1790 Broadway, New York, manufacturer of demountable automobile rims and parts.

Rubber Insulated Metals Corp., Plainfield, N. J., manufacturer of tires, tubes and insulated tools.

Universal Shock Eliminator, Inc., 8 West Sixty-second Street, New York City, manufacturer of shock eliminators, safety buffers.

Wagner-Hoyt Electric Co., 1902 Broadway, New York City, manufacturer of starting, lighting, ignition batteries and switches.

—

Lyons Fair Despite War

NEW YORK CITY, Oct. 12—American manufacturers will have an opportunity of exhibiting their wares in southern France at the annual fair at Lyons which will be held, despite the war, on March 1 to 15, 1917. The State Department has placed $500 at the disposal of the American consul which will enable him to distribute the catalogs, etc.

Catalogs may be forwarded directly to the U. S. Consul at Lyons, and should be printed in French.

—

Demountable Top for Buick

NEW YORK CITY, Oct. 17—The Buick Motor Co. is equipping its touring cars with an all-weather top which is demountable. This body will be standard equipment and will cost $212 extra in this city.

—

All-Weather Top for Chevrolet

NEW YORK CITY, Oct. 17—The Chevrolet Motor Co. is supplying as standard equipment an all-weather top which is removable. This top, which is made by the Detroit Weather Proof Body Co., will cost $70 extra.

—

S. A. E. Reports Accepted

(*Continued from page 679*)

ards should be mainly confined to results, not means, except in cases where conclusive and recognized data are at hand. K. W. Zimmerschied, General Motors Corp., on the contrary, urged that uniformity of war trucks was of greater importance than what construction is best. F. A. Whitten, General Motors Truck Co., held out for more detailed specifications on the plea that safety demands the use of that which is known to be good, regardless of possible merit of unrecognized designs. Mr. Souther suggested a tread to fit railroads, since many will run on rails. Written discussions by John Younger, Pierce-Arrow Motor Car Co., and C. H. Taylor, Republic Motor Truck Co., disagreed with the detail requirements.

All agreed subject too big for hasty action. A. L. Riker said single paragraphs should be whole papers for discussion.

Engine and Transmission

Chairman W. T. Fishleigh of the engine and transmission division, reported progress on valve-timing data with characteristic curves, standards for poppet valves, starting cranks and belts for fans. Engine support arms and fans were delegated to sub-committees, but the division submitted engine test forms for action. Detail changes suggested and extension to cover aero and tractor engines were agreed upon for final submission in January. R. McA. Lloyd, consulting engineer, urged quick action, as standard engine test forms are greatly needed.

Industrial Miscellany

Factory

Stearn's Wear Proof Tire Co., Canada, with W. H. Matthews as president and offices in Toronto, Ont., has secured the Canadian manufacturing rights for the Stearns wear proof inner tubes.

Falls Motors Corp., Sheboygan Falls, Wis., office and shop executives, has organized an association for the promotion of business and industrial efficiency and social welfare.

Ladish-Obenberger Drop Forge Co., Milwaukee, has arranged for considerable extensions of its plant in Cudahy, Milwaukee county. Ground has been broken for a one-story steel and brick addition, 50 by 200 ft. The plant has been operated on a 24-hr. basis for many months.

Waukesha Motor Co., Waukesha, Wis., will award contracts for the erection of its new administration building, which will embody quarters for the engineering department and draughting rooms. The building is to be of brick and steel, 44 by 88 ft., two stories and basement, and cost $25,000.

Geo. P. Meyers Machine Co., Sheboygan, Wis., manufacturing Wisconsin motor trucks, is building its first 5-in. model.

Paige-Detroit Motor Car Co., Detroit, has received an order from the Bigelow-Willey Co. of Philadelphia for $129,000 worth of enclosed cars. This is one of the largest orders for enclosed cars that the company has received.

Federal Rubber Mfg. Co., Cudahy, has started work on the new six-story manufacturing building. It will be 100 x 157 ft. in size and cost $200,000. It is one of the principal units of the $1,000,000 improvement scheme undertaken some time ago, after the Fisk interests bought the controlling interest from the Milwaukee stockholders.

Savage Tire Co., San Diego, Cal., will add a warehouse of brick and steel construction, adjoining its present building.

Minnesota Tire & Rubber Co. will be formed with a capital stock of $200,000 by H. L. Werner, Red Wing, Minn; H. A. Trenholm, Minneapolis, and J. W. Adams, Ellsworth, Wis. Headquarters will be at St. Paul, Minn. The plant location has not been decided on.

Sterling Automobile Mfg. Co. is rushing its plant at Amston, Conn. The company now occupies a plant in Paterson, N. J.

Partridge Rubber Co., Montreal, Ont., will take over the plant of the Standard Tire & Rubber Co., Guelph, Ont.

Star Motor Car Co., Cincinnati, Ohio, has been formed with $200,000 capital and will establish a plant for assembling steam-driven automobiles. R. M. Wallingford, 1003 Race Street, is secretary.

Keystone Tire & Rubber Co., Pittsburgh, Pa., will build a new plant at Penn Station along the Pennsylvania railroad. The plant will consist of a factory building, three stories, 60 by 190 ft., and of brick and steel construction.

Commercial Automobile Co., Lexington, Ky., will equip a plant for assembling automobile running gears and bodies and for the manufacturing of bodies, etc. The equipment will cost $8,000.

Twin City Four Wheel Motor Drive Co., St. Paul, Minn., is building an addition to cost $30,000.

Mohawk Rubber Co., Akron, Ohio, is gradually finishing its $100,000 addition. The new addition consists of a three-story annex to the building recently completed and an additional story on an old building.

F. L. Jacob Co., Detroit, Mich., will build a one-story factory for the manufacture of automobile parts at a cost of $30,000.

E. H. Orersmith, Jonesville, Mich., who is building motor trucks of the front-drive type on a small scale, is negotiating with the business men's association of Waukesha, Wis., with a view to establishing a plant at that point.

American Brass Co., Kenosha, Wis., has awarded contracts for the erection of a new office building, 48 by 100 ft., three stories and basement, and a private garage and service shop, 30 by 120 ft., one story high. Both structures will be of fireproof construction equipped with sprinkler systems.

Personals

N. A. Young has been made sales manager of the Angsten-Koch Co., Chicago. He was formerly assistant sales manager of the Metal Specialties Mfg. Co.

R. V. Lull has been made sales promotion manager of the King Motor Car Co., Detroit. He was formerly in the sales department.

H. A. Harris, formerly of the Hudson agency at Portland, Me., has been appointed manager of the Oldsmobile branch there.

P. W. Runyan has been put in direct charge of publicity by the Westcott Motor Car Co., Springfield, Ohio. He was formerly assistant to sales and advertising manager of the Robbins & Myers Co., Springfield.

The Automobile Calendar

ASSOCIATIONS

Oct. 25-26—Columbus, Ohio, Automobile Trade Assn., second annual meeting, Virginia Hotel.
Oct. 26—Philadelphia, Pa., Section meeting of Society of Automobile Engineers. Paper by Herbert Chase.
Dec. 2-9—Electricians' Country-wide Celebration.
Jan. 9-11—New York City, Society of Automobile Engineers Mid-Winter meeting, Thursday, Jan. 11, S. A. E. day. Annual Banquet, Hotel Biltmore, Special performance Ziegfeld's Midnight Follies.

CONTESTS

Oct. 21 — Kalamazoo, Mich., Track Racee, Kalamazoo, Motor Speedway.
Oct. 22-23—Loe Angeles, Cal., Commercial Car Reliability Tour.
Oct. 28—New York Speedway Race, championship.
Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.
Nov. 18—Phoenix, Ariz., 100-mile free-for-all Track Race. Arizona State Fair.

1917

April—Loe Angeles to Salt Lake City Road Race.
May 19—New York Metropolitan Race on Sheepshead Bay Speedway.
May 30—Indianapolis Speedway Race, Championship.
June 9—Chicago, Ill., Speedway Race, Championship.
June 23 — Cincinnati, Ohio, Speedway Race.
July 4—Omaha, Neb., Speedway Race, Championship.
July 14 — Des Moines, Iowa, Speedway Race, Championship.
July 28—Taooma, Wash., Speedway Race, Championship.
Aug. 4—Kansas City Speedway Race.
Sept. 3—Cincinnati, Ohio, Speedway Race, Championship.
Sept. 15 — Providence, R. I., Speedway Race, Championship.
Race, Championship.
Sept. 29—New York, Speedway
Oct. 6—Kansas City Speedway Race.
Oct. 13—Chicago Speedway Race.
Oct. 27—New York Speedway Race.

SHOWS

Oct. 14 - 21 — Dallas, Texas, Show, State Fair.
Oct. 14-21 — Pitteburgh, Pa., Thirteenth Annual Show, Motor Square Garden. Automobile Dealers' Assn. of Pittsburgh.
Nov. 10-18—Providence, R. I., Show, Rhode Ieland Automobile Dealers' Assn.
Nov. 20-25—Worceeter, Mass., Show, Worcester Casino; Worcester Automobile Dealers Asen.
Dec. 2-9 — Springfield, Mass., Show, Auditorium. H. W. Stacey. Mgr.
Dec. 30-Jan. 6—Cieveland, Ohio, Sixteenth Annual Show, Wigmore Colleeum, Cleveland Automobile Club.
Jan.—First Pan-American Aeronautic Exposition, New York City; Aero Club of America, American Society of Aeronautic Engineers, Pan-American Aeronautic Federations.
Jan. 6-13, 1917—New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.
Jan. 9 - 10 — Fort Dodge, Ia., State Convention, Iowa Retail Automoblie Dealere' Assn.
Jan. 27-Feb. 3, 1917 — Chicago, Ill., Show, Colliseum, National Automobile Chamber of Commerce.
Jan. 26-27—Montreal, Que., Automobile Trade Assn.
Feb.—Newark, N. J., Show, First Regiment Armory.
Feb. 3-10—Minneapolis, Minn., Show, Minneapolis Automobile Trade Assn.
Feb. 10-18—San Francieco, Cal., Pacific Automobile Show, G. A. Wahlgreen, Mgr.
Feb. 18-25—St. Louie, Mo., Show, Auto Manufacturers' and Dealers' Assn.
Feb. 19-24—Syracuse, N. Y., Show, State Armory, Syracuse Dealers Asen.
Feb. 26-March 3—Omaha, Neb., Show; Auditorium, Omaha Automobile Show Assn.
March 6 - 10 — Boeton, Mass., Show, Mechanics' Bldg., Boeton Automobile Dealers' Assn.
March 6-10—Ft. Dodge, Iowa, Northern Iowa Show, New Terminal Warehouse, G. W. Tremain, Secretary.
March 14-17 — Davenport, Ia., Show, Colleeum Bldg. Tri-City Automobile Trade Asen.

TRACTOR

Oct. 14-29—Dallae, Tex., Demonstration, Texas State Fair.

Ford Owners—A Cowl Board and Speedometer Combined

This is the latest of all the famous Stewart Products for Ford cars—and already one of the most popular.

The cowl board, beautifully enameled in black, adds undeniable finish and distinction to the Ford dash.

A Stewart Speedometer is mounted flush in the center—right where it is most convenient and easiest to read.

This combination complete costs but little more than the speedometer alone.

No wonder it is selling so fast. Better get yours today.

Speedometer Complete with Cowl Board, $11.25

"No car is better than its accessories"

Kerosene Oil Men's Fuel Choice

Resolution Adopted Recommending Kerosene— Endorse Good and Holley Vaporizers

CHICAGO, ILL., Oct. 24—That the use of kerosene offers the most hopeful solution of the fuel supply difficulty is a resolution accepted by the Independent Oil Men's Assn. and is the result of the report of a committee consisting of Prof. Lucke, head of the engineering department of Columbia University, Prof. Metzler of the same institution and M. J. Byrne, Waterbury, Conn. This committee was called the Gasoline Relief Committee and was appointed last April, since when it has examined a large number of devices and now recommends two specifically. One is the Good kerosene carbureter, the invention of John Good of Brooklyn, and the other the Holley kerosene carbureter.

To Have Fitting Experts

The Independent Oil Men's Assn. will arrange to appoint in each large city a special repairman to convert existing cars from gasoline to kerosene-burning vehicles and it is stated that the association may even go so far as to finance the repairshop for this purpose. This is sufficient proof that the association is absolutely committed to its resolution and will do everything possible to encourage the use of kerosene.

The convention at which this important resolution was passed is the eighth and was the best which the association has ever had, there being over 800 members present.

Anderson Buys Chicago Electric

DETROIT, MICH., Oct. 20—The Anderson Electric Car Co. has purchased the Chicago Electric interests of the Walker Vehicle Co. and will shortly take over all the new Chicago Electrics completed and those in process of manufacture, together with all parts and service. The Walker Vehicle Co., which is owned by the Commonwealth Edison Co., will devote its efforts to the building and selling of Walker electric trucks. Gail Reed, general sales manager of the Walker company, has been engaged to promote the sale of electrics for the Anderson company.

—

Hackett Resigns Hackett Co. Presidency

JACKSON, MICH., Oct. 24—Mansell Hackett, president of the Hackett Motor Car Co., this city, has resigned the presidency to become the general manager of the company. J. S. Johnston of the Johnston Bros., shipbuilders at Ferrysburg, Mich., is the new president and J. L. Dornbos, cashier of the People's Savings Bank, Grand Haven, Mich., becomes treasurer. Other officers remain the same.

—

Miller Is Inland Sales Head

ST. LOUIS, MO., Oct. 20—L. B. Miller has been appointed sales manager of the Inland Machine Works, this city, maker of the Inland piston ring. He was formerly office manager of the St. Louis branch of the United States Tire Co.

—

Bour-Davis Starts Production

DETROIT, MICH., Oct. 23—The Bour-Davis Motor Car Co. has started production in its new plant, which has been building for nearly a year. The plant is a four-story building and the progressive assembly principle will be used.

—

American Motors Plant Adopts 8-Hr. Day

PLAINFIELD, N. J., Oct. 23—The 8-hr. day will be put into effect at the plant of the American Motors Corp., this city. The plant will employ several hundred men beginning Nov. 1.

Packard Surplus Is $10,823,717

Gains $6,206,419 in Final Year —Total Assets Increase $11,830,505

DETROIT, MICH., Oct. 20—Packard assets have increased $11,830,505 during the past year. More than $6,000,000 have been added to the surplus, and a general prosperous business growth is displayed in the consolidated balance sheet for the fiscal year ending Aug. 31, which was submitted to stockholders of the Packard Motor Car Co. at their annual meeting in the company's general offices Thursday, Oct. 19. The report presents the company's financial statement and several paragraphs of explanation, among which it is stated that plant values amounting to $1,250,000 were written off in excess of regular depreciation, making the total depreciation written off the Detroit plant, $2,847,-648.76 for the fiscal period.

The consolidated sheet of the Detroit and subsidiary companies shows $6,206,-419.61 added to surplus for the year and an increase of $9,094,388.88 in value of inventories comprising raw material, work in progress and finished vehicles. The increase in inventories, it is explained, was not as great as the company's increase in vehicle production which was 186 per cent greater than in the preceding year.

During the year the company's authorized capital stock was increased from $16,000,000 to $21,000,000 by the addition of $5,000,000 par value of common stock, and the issued capital stock was increased from $7,065,300 of common and $5,000,000 of 7 per cent cumulative preferred stock to $11,656,930 of the authorized $13,000,000 of common stock and to the total $8,000,000 of authorized pre-

Red Seal Battery Maker Enlarges

Re-Incorporates with Capital of $5,000,000—To Increase Production and Plant

NEW YORK CITY, Oct. 24—To take care of increased production and factory facilities, the Manhattan Electrical Supply Co. has re-incorporated with a capital of $5,000,000, divided into $1,500,000 7 per cent cumulative first preferred, $500,000 second preferred, also 7 per cent cumulative, and $3,000,000 common. The old capital was $1,500,000, divided into $175,000 preferred and $1,375,000 common. The common paid 14 per cent and the preferred 6 per cent.

This company, which manufactures and sells the Red Seal battery and also deals in a line of electrical appliances at its various stores, was founded in 1889 with a capital of $1,300.

Gross Sales	Year
1901	$902.324
1915	3,644,037
To Aug. 31, 1916	2,812,040

There will be no change in the present officers, who are: J. J. Gorman, president, and B. H. Ellis, vice-president and treasurer. Factory facilities will be added and new machinery installed.

The current net earnings applicable to dividends are estimated at more than five times the first preferred requirements. In the period of 2 years and 8 months to Aug. 31, 1916, the average earnings were more than four times the first preferred dividend requirements.

The net tangible assets, exclusive of good will, patent rights and trade marks, as of Aug. 31, 1916, were over $2,490,000, or $166 for each share of first preferred stock, and net quick assets more than $1,600,000, or $106 per share. Up to Aug. 31, there was $489,847.91 cash in the bank.

The company will have no mortgage or funded debt of any kind. There will be a sinking fund, beginning Oct. 1, 1917, of $30,000 per annum, payable $7,500 quarterly to and including Jan. 1, 1921, and thereafter $40,000 per annum, to be applied to the retirement of the first preferred at not over $112.50 per share.

—

Columbia Motors Leases Boat Plant

DETROIT, MICH., Oct. 23—The Columbia Motors Co. has leased the plant of the Michigan Steel Boat Co. and will take possession early in December.

—

Banta Is Premier Vice-President

CHICAGO, ILL., Oct. 23—A. J. Banta, branch manager in Chicago for the Locomobile Co. of America, resigns Nov. 1 to become vice-president of the Premier Motor Corp., Indianapolis. Mr. Banta has held his present position with the Locomobile Co. for the past 12 years. He is succeeded by J. Murray Page, manager of the Los Angeles branch of the Locomobile Co. Mr. Page has been in the service of this concern since 1899, spending part of that time in the Locomobile factory, and a part as branch manager in San Francisco.

—

Hal Motor Car Co. Now

DETROIT, MICH., Oct. 20—The H. A. Lozier Co., Cleveland, has brought the name of that company into harmony with the car they manufacture and has reincorporated as the Hal Motor Car Co.

—

Sattley is Standard-Detroit Manager

DETROIT, MICH., Oct. 23—F. L. Sattley has been named general manager of the Standard-Detroit Tractor Co. Mr. Sattley is a member of the well known family of implement manufacturers.

—

Sproat is Olds Works Manager

LANSING, MICH., Oct. 24—H. J. Sproat has been appointed works manager of the Olds Motor Works, this city. His immediate duties will be the enlargement of the factory to provide for an increase of production to more than 20,000 cars next year, almost double that of last.

—

Hughes Resigns from Victor Parts

CINCINNATI, OHIO, Oct. 24—W. R. Hughes has resigned as sales manager of the Victor Auto Parts Co., this city, and is now secretary and treasurer and also manager of sales of the Corcoran Mfg. Co., this city.

—

Raybestos Co. Incorporated for $1,500,000

Will Take Over Royal Equipment Co. and Expand

BRIDGEPORT, CONN., Oct. 24—The Raybestos Co. has been incorporated under Connecticut laws with $1,500,000 capital and will take over the Royal Equipment Co., manufacturer and distributer of Raybestos brake lining, brakes, etc. There will be no change in the policy of the company or the character of its products; dealer and jobber arrangements also remain unchanged. A 15-acre factory site has been purchased in Bridgeport and six new buildings will be erected which will double the capacity of the plant. There will be two buildings 100 by 600 ft., for weaving brake lining; one building 100 by 200 ft., for manufacture of brakes; one building 60 by 200 ft., for treating Raybestos; one building 60 by 300 ft., for manufacturing compressed sheet; one building 60 by 300 ft. for a storehouse and shipping department.

White Surplus Is $1,623,521

Co.'s Total Income for First 6 Months of 1916 Fiscal Year is $2,750,923

NEW YORK CITY, Oct. 21—The White Motor Co., Cleveland, Ohio, reports a surplus of $1,623,521, which is equivalent to 11 per cent on the $16,000,000 capital stock. Net profits from operations were $2,635,784 during the 6 months ending June 30, 1916. Adding $115,208 in other income, brings the total income to $2,750,923. The expenses of the company amounted to $847,472 and the dividends up to the March 31 quarter to $280,000, thus bringing the surplus to $1,623,521.

The company has $16,000,000 capital stock, $50 par value, with no bonds and no preferred stock. The company is paying 7 per cent dividends on the stock. Net profits in the year 1915 were approximately $8,700,000, over 54 per cent on the stock.

The combined balance sheet of this company and subsidiary companies as of June 30, 1916, as reported to the New York Stock Exchange, follows:

ASSETS	
Plant, equipment and real estate	$3,558,547
Good will, patents, etc	5,388,910
Materials and supplies	5,539,025
Accounts receivable	2,112,932
Bills receivable	804,967
Cash	2,022,337
Deferred assets	114,991
Total	$19,541,710
LIABILITIES.	
Capital stock	$16,000,000
Purchase money obligations	390,000
Current accounts, etc	1,282,535
Reserve for depreciation	85,902
Accounts and bills receivable	159,751
Surplus	1,623,521
Total	$19,541,710

Weidely Capital Now $600,000

INDIANAPOLIS, IND., Oct. 23—The Weidely Motors Co. has just increased its capital stock from $350,000 to $600,000.

National Plans for Expansion

Offers 53,000 Shares in New Financing—6000 Cars for 1917

NEW YORK CITY, Oct. 23.—One more company has joined the list of those which have been refinanced to take care of a larger production. The latest is the National Motor Vehicle Co., Indianapolis, Ind., which will be taken over by the National Motor Car & Vehicle Corp., organized under the laws of New York. The new company, which at first will be a holding concern, is offering 53,000 shares of stock to the public at $42.50 per share. Twenty-seven thousand of these have been taken by the present National Motor Vehicle Co. interests. In other words over one-third of the total outstanding stock of the new company is to be taken by the present management and its associates. The company has no mortgage, no bonded indebtedness and no preferred stock. The refinancing is being handled by Pyne, Kendall & Hollister, and Leonard Snider & Co. The total capitalization is 80,000 shares without par value.

Additions Under Way

The company is making several additions to its plant and the minimum output for 1916 has been placed at 6000 cars, as against 2499 cars last year.

The company is completing a new reinforced concrete building, 60 by 380 ft., three stories, which is located between the original buildings and the 400-ft. buildings completed last January. This addition gives a total of 626,000 sq. ft. floor space. Another strip of ground has recently been purchased on the east side of Yandes Street, opposite the present site, on which a further addition of a building is contemplated, 140 by 328 ft., one-story high for the present.

It is estimated that the net earnings for the year ending June 30, 1917, will be from $1,000,000 to $1,100,000 on a maximum output of about 6000 cars. This estimate is based upon orders actually taken and on contracts made by the company for needed materials. This is at the rate of 30 per cent on the subscription price of $42.50 per share. Last year the earnings were $425,000, equal to 12½ per cent on the capitalization of the new company at the issue price.

Management Unchanged

The management remains unchanged. The officers of the existing company are: A. C. Newby, president; W. G. Wall, vice-president; and G. M. Dickson, general manager, secretary and treasurer.

The proposed directorate of the new company includes: A. C. Newby; S. A. Fletcher, president of the Fletcher-American National Bank, Indianapolis; O. J. Thomen, of Redmond & Co., New York; Leonard Snider of Leonard Snider & Co., New York; W. G. Wall; G. M. Dickson, and Buell Hollister of Payne, Kendall & Hollister, New York.

—

Ford Co. Raises Probationary Salary

DETROIT, MICH., Oct. 24—The Ford Co. has raised the salaries of workmen laboring under the probation system to 43 cents an hour, an increase of 9 cents over the former rate of 34 cents per hour. Ford employees are placed on a probation basis for 6 months and do not receive the $5 a day salary until they qualify through their probation. As the Ford work day is 8 hr., probationers now receive $3.44 per day in place of $2.72. The raise was made because of the increased cost in living.

All women workers in factories and offices will receive the same wages as the men, $5 per day after probation.

—

Standard Motor Parts Buys Newcastle Company

NEWCASTLE, IND., Oct. 23—The Newcastle Auto Parts Co. was sold last week to the Standard Motor Parts Co., this city. The latter company took over more than $3,000 worth of obsolete Maxwell-Briscoe and Everett parts. The Newcastle Auto Parts Co. was incorporated 2 weeks ago with a capitalization of $200,000, and at the time of its organization announced it would occupy 20,000 sq. ft. of floorspace in the manufacture of parts, accessories and appliances for automobiles.

—

Pullman Advances Car Price $85

Co. Will Concentrate on Four-Cylinder at $825

YORK, PA., Oct. 24—The Pullman Motor Car Co., this city, has advanced its price to $825 on its 1917 models. The company will concentrate on a four-cylinder model next year with a 32 hp. motor. There will be three types, including a two-passenger roadster, a four-passenger roadster and a five-passenger touring car.

The motor is little changed from last year, the changes covering mainly refinements. The bodies will be streamline and the standard color will be green. Other features include combined force feed and splash with an indicator on the dash; Splitdorf starting and lighting; Carter vacuum tank for carbureter feed; Dixie magneto; and Stromberg carbureter.

Corliss Truck Is Unique

Special Patented Design Combines Frame and Body in Integral Unit

CHICAGO, ILL., Oct. 23—The Corliss Motor Truck Co., Corliss, Wis., is a corporation formed some time ago which is now manufacturing and ready to supply a new type of small truck. It is rated at 1000 lb. capacity and sells for $695, the especial point being the use of an all-steel body, which is combined with the frame in such a way as to make the body a strength factor in the chassis. Because the weight of the body is thus utilized the weight of the complete car can be reduced without losing any strength.

The engine fitted is a four-cylinder 3⅛ by 4½ in. and there is a three-speed gearset with selective shift. The rear axle is bevel-driven, three-quarter floating and has double roller bearings to carry the load. Elliptic springs are used and pneumatic tires 31 by 4 in., the wheelbase being 100 in. The details are of a robust character.

It is stated that the company have excellent factory facilities and will be able to care for a large demand.

—

Canadian Ford Passes Dividend

DETROIT, MICH., Oct. 24—The Ford Co. of Canada has passed its dividend on account of large expenditures for additions and a war tax of $750,000. The directors re-elected Henry Ford president; G. M. McGregor, vice-president and treasurer, and W. R. Campbell, secretary.

The Canadian company earned for the fiscal year of 10 months ending July 31, $1,109,322.14, equal to 15.8 per cent on the outstanding $7,000,000 of the company's authorized $10,000,000 of capital stock.

—

Gordon Is Hudson Traffic Manager

DETROIT, MICH., Oct. 25—John Gordon has become traffic manager of the Hudson Motor Car Co., this city. Mr. Gordon was formerly with Dodge Bros.

—

Fifth Avenue Buses Earn $1,669,726.18

NEW YORK CITY, Oct. 24—The Fifth Avenue Coach Co., this city, during its fiscal year, ending June 30 last, carried 16,223,042 passengers at 10 cents each, in its 132 buses, its revenue from this source amounting to $1,622,304.20, an increase of $217,257.10 over the previous period's operations. The company made 33.10 cents per active bus mile. Revenue from livery service, 19,460 bus miles, amounted to $16,281.66 and advertising

privileges netted $31,140.32, thus bringing the total revenue from operations to $1,669,726.18, an increase of $218,218.08 over the previous period. After deducting total operating expenses of $1,064,690.36, the income was $458,672.90, $94,498.70 more than last year.

A feature brought out in the report of the company is that the 132 buses ran at a cost of only 21 cents per bus mile, each bus using six tires, the rear wheels each having two tires. This is based on a mileage of 4,966,995 and a total operating expense of $1,064,690.36. New tires during 1916 cost $54,533.63.

—

Daimler Representative Describes Tanks

DETROIT, MICH., Oct. 23—A. C. Hills of the English Daimler Co. is visiting Detroit on behalf of his company and of the British government. He is making a short trip and will be in the U. S. A. less than 2 weeks. Hills is credited with saying that the famous "tanks" are engined with Daimler power plants and are about 60 ft. long. Their weight, he says, is sufficient to push down a 6-in. tree trunk when the tank is driven direct at the tree. The original report that the tanks are composite vehicles made in different factories is thus confirmed.

A. C. Hills has been a prominent member of the British motor industry for many years and has been with the Daimler company since a short time after the latter's adoption of the Knight engine.

—

National and Premier Co.'s In New York

NEW YORK CITY, Oct. 25—The National Motor Car and Vehicle Corp. has been incorporated with 80,000 shares of no par value, to carry on business with $800,000. The incorporators are R. S. Dodge, J. R. Lindemuth.

The Premier Motor Corp. has been formed with a capital of 20,000 shares, $100 each, and 30,000 shares of no par value, to carry on its business with $2,150,000. H. L. Thompson, I. P. Seery and J. C. Flowers, president of the company, are the incorporators.

—

Steel Tube Products Co. Formed

DETROIT, MICH., Oct. 21—The Michigan Steel Tube Products Co. has been incorporated for $300,000 by Charles E. Miller, Howard A. Flagg and Frank Kritz, all formerly with the Standard Welding Co. of Cleveland. The new concern will manufacture steel tubing.

—

Troy Mfg. Co. Buys Studebaker Building

DETROIT, MICH., Oct. 24—The Troy Mfg. Co. has purchased the factory known as plant 5 of the Studebaker Corp. for $100,000. The Troy company will use the factory for the manufacture of automobile bodies.

Cleveland Considers Steam

—

Abner Doble Describes His System to S. A. E. Section —Good Discussion

CLEVELAND, OHIO, Oct. 21—In a long paper tracing the development of the steam automobile in recent years Abner Doble of Detroit held the close attention of the Cleveland S. A. E. section last night. Doble dealt with the main factors which make for steam car success and failure, showed why it was that some of the earlier cars gave trouble and traced different methods by which the troubles had been overcome. He described his own boiler and engine system, already dealt with in THE AUTOMOBILE for Sept. 7, and explained how this came to be created by studying other types. The paper was extremely informative, and will be printed at length next week.

An excellent discussion followed the paper, and, in answering the questions asked, Mr. Doble touched upon both matters which had entered into his paper and others which he had left out in order that the paper might not be of too great a length. In answer to the first question, which was regarding the relative thermal efficiency of his steam power plant and a standard internal combustion engine, Doble pointed out that, at normal running speeds, the thermal efficiency of the steam engine is much nearer its maximum than is that of an internal combustion engine; in other words, that he did not claim a greatly increased thermal efficiency for his own power plant, but rather believed that there had always been a tendency to overestimate the thermal efficiency of internal combustion engines when pulling a heavy load at low speed.

The Weight Question

In regard to the difference in weight distribution caused by the placing of the engine upon the rear axle, Mr. Doble believes it to be a distinct advantage rather than disadvantage. One reason for this, upon which he laid emphasis, was the bringing the center of gravity of the car back to a point somewhat behind the physical center of the car, thereby improving the conditions of traction and lessening the tendency to skid.

When asked about the action which took place when the condensation of steam was allowed to form water in the cylinders, Mr. Doble described a feature of his engine which had not been brought out in his paper; viz.: a special design of valve whose lifting from its seat allowed either water or steam to escape into the steam chest whenever cylinder compression exceeded steam chest pressure.

Various questions were next brought up concerning the fuel used and how it was supplied to the combustion system, to which Doble answered that no gasoline was used either in starting or running, kerosene being the only fuel carried, and that the kerosene was supplied to the combustion system by a pump without the use of air pressure.

The great differences between the lubrication of a steam engine and an internal combustion engine were effectively brought out in the discussion among a number of those present, Doble first bringing up the point of the lubricating qualities of the steam itself which was borne out in an exceedingly interesting way by one who had had considerable experience along this line in connection with locomotive work. Mr. Doble went on to say that the chief advantage of the oil which he did use was to keep the engine from rusting and the inner surfaces of the boiler from accumulating deposits.

—

U. S. A. Cars Sunk at Sea

NEW YORK, Oct. 24—The Dutch liner, Blommersdyk, bound for Rotterdam on Oct. 9, had on board twenty-five cases of automobiles and parts, without tires, when it was sunk by the German submarine U-53 off the coast of New England. The boat also carried one truck. The cars, it is stated, were shipped by the Kissel Motor Car Co. to its representative in Amsterdam.

A consignment of Scripps-Booth cars went down with the Lord Treegar when it was recently sunk by a torpedo in the Mediterranean.

—

$750,000 Co. Formed in Maine

PORTLAND, ME., Oct. 21—The Pilgrim Motor Co., an organization with a capitalization of $750,000 has been formed here to manufacture and deal in automobiles and accessories. The men behind it are all Maine residents. T. L. Croteau is president; James E. Mantir, secretary; A. B. Farnham, treasurer. These men with George S. Soule comprise the board of directors.

—

Doak Joins Ohio Electric

TOLEDO, OHIO, Oct. 21—R. C. Doak has been appointed assistant general sales manager of the Ohio Electric Car Co., this city. Mr. Doak has been in the electric car field since 1910 when he became branch manager of the Woods company. From there he went to the Anderson company and later returned to the Woods company.

—

Bowser Buys Site for Addition

FORT WAYNE, IND., Oct. 23—The S. F. Bowser Oil Tank & Pump Co. has bought a large tract of land, occupying an entire square, south of the present factory.

New York Registers 303,223

267,825 Passenger Cars, 32,942 Trucks and 2456 Dealers' Licenses Issued

NEW YORK CITY, Oct. 22.—For the first time in the history of this or any other State in this country, the registration in New York State has exceeded the 300,000 mark, exactly 303,223 cars and 98,203 persons having been licensed to date. There is now one automobile to each thirty-two persons in this State, the last census showing a population of 9,687,744 persons.

The combined total of motor vehicles in New York includes 267,825 passenger cars, 32,942 commercial vehicles and 2456 dealers' automobiles. Of the passenger cars, 139,026 were of 25 hp. or less, 82,191 less than 35 hp., 23,411 less than 50 hp. and 1001 of 50 hp.

The total of 98,203 chauffeurs includes 71,194 persons who were licensed last year and who have renewed their licenses this year for the first time.

The use of motor vehicles in this State has grown more rapidly this year than in any previous one since they became common. Figured upon a percentage basis, however, this increase is not quite so apparent, as the number registered this year has increased 27 per cent. Last year the increase was 31 per cent, the year previous 26 per cent and the year before that 25 per cent. In 1912 the gain was 27 per cent, in 1911 it was 24 per cent over 1910, the first year to require annual registration.

The total number registered has more than doubled since 1913 and is almost twice as much as the total registered in 1914, when there were 169,966. This year's registration is nearly five times that in 1910.

190,000 Cars in Iowa

DES MOINES, IOWA, Oct. 23—Iowa already has over 190,000 automobiles registered for 1916 and the total of registration fees has been $1,636,000 or an average of $8.58 per car. The number of dealers registered is 2641 and the fees from dealers amount to $86,547.

23,033 Cars in Alabama

MONTGOMERY, ALA., Oct. 19—The license year in this State ended Sept. 30 and 23,033 automobile licenses were issued, a gain of 100 per cent. Of these 17,740 were for pleasure cars, 3,888 for commercial trucks and 1,397 for motor cycles.

Cotton Prices Boost Car Sales

ATLANTA, GA., Oct. 19—Automobile licenses are being issued in this State at about the rate of 100 a day since cotton passed 16 cents. Last year 25,000 licenses were issued. Two weeks ago the 45,000 mark was passed for this year and it is expected that the 50,000 mark will be passed. Charles S. Barrett, President of the Farmers' Union, on his return from an extended inspection trip was asked as to the most notable feature of his trip. "The cotton money that is going into automobiles," he said.

115,000 Cars in Wisconsin

MILWAUKEE, WIS., Oct. 21—The first census of motor-propelled vehicles taken in Milwaukee and Wisconsin just 10 years ago to-day, showed that there were 746 cars owned in Milwaukee, and 2578 in the State, including Milwaukee. To-day it is figured that there are 18,000 cars owned in Milwaukee, and approximately 115,000 in Wisconsin.

Discher Patent Held Valid

MILWAUKEE, WIS., Oct. 20.—The Discher patent covering bumper bracket construction has been held valid and infringed by the Auto Parts Mfg. Co., of this city, and a permanent injunction has been granted in favor of Grant F. Discher, president and general manager of the Gemco Mfg. Co., this city, which controls the patent. The patent, No. 1,052,224, relates to a bumper bracket having a lug, which bears against the front end of the automobile frame side member, and an adjustable clamp, using a transverse bolt passing through two vertical slots, one on each side of the frame member.

John F. Harper has been appointed special master to determine damages. The decree was handed down by Judge Geiger in the U. S. district court for the Eastern district of Wisconsin.

The Auto Parts Mfg. Co. petitioned for an appeal to the U. S. circuit court of appeals for a temporary suspension of the injunction. The court granted the suspension on condition that the company file a bond for $15,000 to cover any damages that might be sustained while the appeal was pending, should the higher court confirm the decree of the district court.

Another Injunction for Prest-O-Lite

INDIANAPOLIS, IND., Oct. 22—The Prest-O-Lite Co., Inc., has been granted a permanent injunction against the Power City Sun-Lite Gas Co., Sioux Falls, S. D., putting its gas into Prest-O-Lite tanks without removing the Prest-O-Lite Co. name and trade mark. The decree was issued by the U. S. district court for the district of South Dakota, southern division.

S. A. E. Assets Are $33,000

209 New Members Added During Year—Hunt Succeeds Baton as Tire Chairman

WASHINGTON, D. C., Oct. 18—The strong financial condition of the Society of Automobile Engineers was shown at to-day's meeting of the Council held in this city when the financial statement for the fiscal year was presented. The society has funds approximating $33,000. At the end of the fiscal year, Sept. 30, the assets were: Certificates of deposits $20,000, savings account $2,000, bonds $10,000 and $860 checking account.

During the year 209 new members have been added as a net gain. In all 370 members have been enrolled, but there have been fifty-eight resignations, ninety-four dropped for non-payment of dues, and nine deaths. The new membership shows 150 members, 105 associate members, fifty-two juniors, five affiliates, seven affiliate representatives, and thirty-five student enrollments.

At to-day's meeting eighteen resignations were accepted and twenty-seven members added. H. L. Baton's resignation as chairman of the tire and rim division of the standards committee was accepted and O. E. Hunt appointed in his place.

Exporters to Meet Oct. 31

NEW YORK CITY, Oct. 24—The American Manufacturers' Export Assn. will meet Oct. 31 at the Hotel Biltmore. The session will be the seventh annual one. More than 400 persons are expected to be present. The afternoon will be devoted to a report of the members of the Industrial Commission to France, who will return to this country on Oct. 28.

Humpage Goes to Wilt Drill

SYRACUSE, N. Y., Oct. 23—F. R. Humpage has resigned as manager of the Dyneto Electric Co., this city, to become affiliated with the Wilt Twist Drill Co., Walkersville, Ont., in the capacity of secretary-treasurer and general manager. Mr. Humpage is well known in the automobile trade, having been with the industry since 1903 in executive positions with the Packard, Thomas and other companies.

Carlton Is Bosch 'Frisco Manager

SAN FRANCISCO, CAL., Oct. 23—B. R. Miller has resigned his position as manager of the San Francisco branch of the Bosch Magneto Co. and L. C. Carlton, previously in the engineering department at the main office, New York, succeeds him.

Steel Prices To Be Steady

No Change Expected for 2 Years—Post Bellum Conditions Will Hold Up Prices

NEW YORK CITY, Oct. 23.—That there will be very little if any reduction in price of steel during the next 2 years is the opinion of a large manufacturer who has the reputation of being closer to the steel situation than anybody else connected with automobile and accessory manufacture. Just at the present time, due to the fact that less steel is being shipped abroad, and due to the seasonal slow-up on the part of automobile manufacturers there is plenty of steel to be had. Steel mills that have been very stingy on shipments are now in a position to make better shipments than formerly. The price remains stiff and there is no indication of any softening of the market.

A sales manager of one of the largest producers of steel entering into automobiles is authority for the statement that steel would be at least $5 a ton higher inside of the next 4 months. He further believes that for the next 3 years the steel market will not be any lower than it is at present. So long as the war continues the demand for steel in U. S. A. will be great in response to the foreign and domestic demands. Even when the war stops a great amount of steel will be required from America for reconstruction work abroad so that there is little possibility of any lowering of the market.

Some of the Detroit automobile concerns report getting plenty of steel without much trouble. Representatives of three steel concerns in Detroit state that deliveries have been behind for the past 10 months, but that at the present time there is no indication of any change pointing towards any shortage different than what has existed.

Marion Tire Elects Directors

MARION, OHIO, Oct. 19—The stockholders of the Marion Tire & Rubber Co. held their first annual meeting at the factory recently, at which the directors were elected for the year. The following members were re-elected to the board of directors: W. H. Heverstott, C. W. Fairbanks, J. W. Jacoby, D. H. Lincoln, J. L. Price, C. W. Mapes, A. H. Trout and W. T. Jones. H. L. Gilbert was also elected a director.

Gilbreth Talks on Motion Study

DETROIT, MICH., Oct. 21—Frank B. Gilbreth, efficiency engineer, Providence, R. I., gave an interesting lecture before the Detroit Engineering Society last night in which he discussed motion study as a science of determining methods of least waste in industry and told of his system of straight-line movement, describing how by means of electric lights and clock and other devices he photographed body movements of workers to ascertain waste and to discover means for efficient labor. Mr. Gilbreth told of many instances where his system has produced results amounting to three times as much production with less fatigue of the workers and described his methods in detail, illustrating many of them by moving pictures.

Kjeldsen, Importers' Show Mgr., Dead

NEW YORK CITY, Oct. 25—Stefan Kjeldsen, manager of the Importers' Automobile Show in this city and Chicago, and with the Holbrook Co., body builder here, died yesterday in this city. He was born in Denmark 34 years ago.

Crude Oil Features Materials Market

NEW YORK CITY, Oct. 24—Crude oil prices featured this week's activities in the automobile materials market. Pennsylvania crude has gone up to $2.60 a barrel, its former record price. Refiners state that it is impossible to get the required quantity of different grades of crude, and the price has again been raised in the hope of increasing the supply. Producers were openly talking of $3 for Pennsylvania crude when they heard of the new quotations.

Gasoline prices, it is stated, may soar, on account of the crude shortage. Some authorities state that on account of the large exports of petroleum, the oil production in this country will be inadequate to supply the increased needs of the refineries. Linseed oil has advanced 6 cents a gallon to 88 on account of higher flaxseed prices. Steel prices are holding strong with no changes. The automobile makers are now contributing their quota to the steel industry by coming in with contracts for the first half of 1917 and closing for their needs of forging bars and alloy steel up to July 1, 1917.

100-Point Rise in G. M. Common

Stock Goes to 830 — Rest of Issues Rise on Sympathetic Market

NEW YORK CITY, Oct. 23—The automobile and accessories issues last week were in larger demand and consequently higher. A majority of the rises were large. General Motors, which rose 40 points the previous week, kept up its skyward movement with another rise of 100 points, reaching the record price of 830. This stock leads the motors while Firestone heads the accessories. Firestone has reached $1,130 a share, just $5 more than last week. The General Motors Corp. has made application to list on the Stock Exchange $20,000,000 of 6 per cent cumulative preferred and $82,600,000 common stock.

Hupp, Miller Rubber, Chalmers, Chevrolet, Studebaker, and United Motors featured with substantial rises. Hupp preferred rose 10 points; Miller Rubber, 10 points; Chalmers, 5 points; Chevrolet, 2 points; Studebaker, 3½ points.

Several new stocks were admitted to the Stock Exchange and Curb last week. White Motor has entered the Stock Exchange and the Spicer Mfg. Co., National Motor Car & Vehicle Co., and the Manhattan Electrical Supply Co. have put their stock on the Curb. Initial transactions on the Curb, Thursday, in Spicer first preferred amounted to 3600 shares with the high sale being 101½, or 1½ points above the price at which it was sold by the syndicate. The company's earnings are now running at the rate of $100,000 net a month. The National stock has been offered at $42.50.

Drulard Graham Roller Bearing Inspector

DETROIT, MICH., Oct. 24—Frank Drulard, chief inspector of the Bower Roller Bearing Co., has resigned to accept a similar position with the Graham Roller Bearing Co., of Coudersport, Pa.

I.M.C. Extends Time To Oct. 30

400 Voting Trust Certificate Holders Have Deposited But Others Delay

NEW YORK CITY, Oct. 23—The International Motor Co. is notifying holders of voting trust certificates of the preferred and common stock that the time to make deposits has been extended to Oct. 30. Over 400 holders, owning two-thirds of each class of stock, have deposited their certificates under the plan and reorganization agreement, but a large number of holders have not been heard from.

The company's indebtedness, aggregating nearly $3,000,000, matures Nov. 1 next. Certificates should be deposited either by mail or in person with the Columbia Trust Co., this city.

Stewart-Warner Earns $604,939 in Quarter Ending Sept. 30

CHICAGO, ILL., Oct. 20—The net earnings of the Stewart-Warner Speedometer Corp. for the third quarter show an increase of more than $150,000 over the earnings for the corresponding period of last year. For the quarter ended Sept. 30 the net earnings were $604,939; for the same period last year they were approximately $450,000. This was announced after a meeting of the directors to-day. It has not been the policy of the corporation to make public such production figures, and this new departure is said to be due to the fact that the stock recently has been listed on the Chicago stock exchange.

Other figures available at this time are those for the entire 9 months of 1916 so far. The net earnings for that period are $1,880,072. Although this shows a continued large increase in business, the directors did not increase the dividend rate or vote an extra disbursement at their meeting to-day.

Dividends Declared

Mitchell Motors Co., quarterly of $1.50 a share, payable Nov. 24 to holders of record Nov. 10.

Stewart-Warner Speedometer Co.; quarterly of 1½ per cent on common, payable Nov. 15. Books close Oct. 30 and reopen Nov. 6.

Pyrene Mfg. Co.; quarterly of 2 per cent on common, payable Nov. 1 to stock of record Oct. 25.

Paige Motor Car Co.; monthly of 3 per cent, payable Nov. 30 to stock of record Nov. 1. Action has been deferred on proposed issue of $1,500,000 preferred stock until Nov. 24.

Miami Trailer Adds $10,000

TROY, OHIO, Oct. 25—The Miami Trailer Co. of this city has increased its capital stock $10,000 to take care of factory additions for trailer manufacture. This action was taken at the annual meeting of the stockholders Oct. 11.

Jones Opens Detroit Purchasing Office

DETROIT, MICH., Oct. 20—The Jones Motor Car Co., Wichita, Kan., has opened a permanent office for its purchasing department at the Kresge Building here.

Michigan Stamping Stock Issue

Automobile Parts Concern Started on $200—Capital Increased to $1,500,000

DETROIT, Oct. 21.—Stockholders of the Michigan Stamping Co. were ratified an increase in capital from $500,000 to $1,500,000 at a special meeting held Oct. 20. The proposed increase will take the form of a stock dividend and will involve a reduction of the par value from $100 to $10 a share. The stock recently listed on the Detroit Stock Exchange is held at $500 a share with none offered.

The Michigan Stamping Co. has experienced a remarkable growth. J. H. French, president of the concern and H. P. Cope, vice-president, started the business 12 years ago with a capital of $200 with which they purchased a stamping machine on monthly payments. With the growth of the industry the company became more prosperous and acquired property which now includes several buildings valued at close to $1,000,000. Last year the company purchased additional land and is now erecting a new plant to cover 6 acres.

Runyan Cushion Wheel Co. Formed

OMAHA, NEB., Oct. 23—The Runyan Cushion Wheel Co. has been incorporated with $100,000 capital to manufacture a patent cushion wheel in this city. The incorporators are: A. L. Runyan, F. C. Burlingim, H. O. Wulff, D. R. Sowards, E. J. Conrad and J. E. Von Dorn.

Hudson Engine in Test Runs

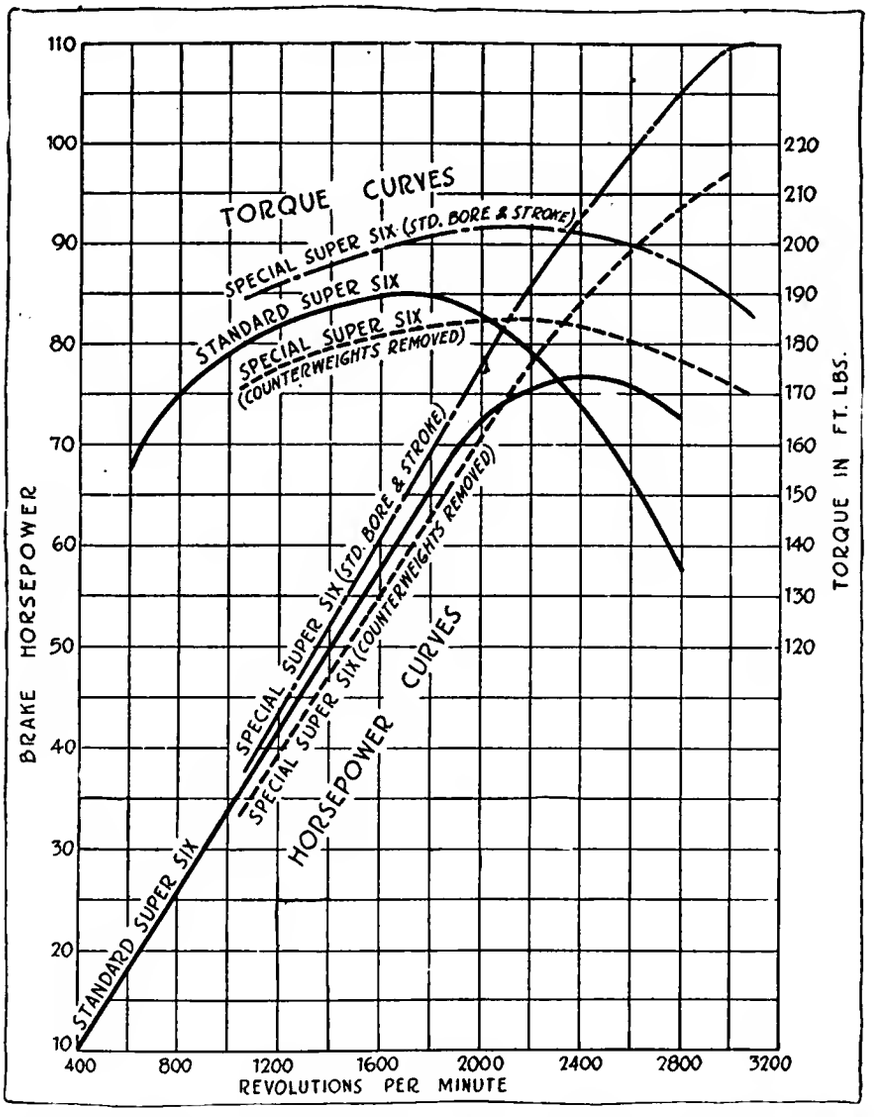
Trials To Prove Counterbalanced Crankshaft Reduces Internal Friction

DETROIT, MICH., Oct. 12—In order to demonstrate the fact that the counterbalanced crankshaft reduces the internal friction of an engine, the Hudson company made to-day a series of runs with the counterbalanced shaft and with the shafting nearly in static balance. The first run was made to obtain maximum power, this being reached at 3100 r.p.m. when 110 hp. was developed. The connecting-rod bearings were then adjusted and a 40-min. run at 3000 r.p.m. was made, the horsepower varying between 100.4 and 103.5. At the conclusion of this second run the weights on the crankshaft were removed and a steel ring attached to the center throw in order to bring the shaft into static balance. This having been done, the test was repeated, first for maximum power and second for endurance. The latter test only lasted for 2 min., 30 sec., as the cap of one of the connecting-rod bearings became loose and was thrown off.

It will be noticed from the curves published herewith that the special engine with which the tests were made both with and without counterweights, gives practically the same reading as the stock Hudson engine up to 2000 r.p.m., but that considerable divergence commences at this point. The similarity between the torque curves of the special Super sixes is characteristic of the kind of difference caused by internal friction.

Double Assessment for Speedway

ST. PAUL, MINN., Oct. 20—Petition for a double liability stock assessment against shareholders in the Twin City Speedway Assn. has been granted Receiver P. W. Herzog, by Judge J. C. Michael, attorney. An informal offer of $180,000 is the best received to date for the plant.



Power curves obtained by Hudson in tests of special and standard Super six engines

Salesmanship Club in New York

Automobile and Accessory Concerns Among Members of Growing Organization

NEW YORK CITY, Oct. 19—The New York Salesmanship Club, which is an outgrowth of the World's Salesmanship Congress held in Detroit in July has been formed and held its initial meeting last evening at the Waldorf-Astoria with about 2000 men present.

The club is one of a number being formed throughout the United States for the "Betterment of Business Through the Betterment of Salesmanship." Its work will include meetings every 2 weeks at which practical sales workers will speak and answer questions in an open forum. The plan is similar to that worked out by the Detroit club, which fathered the Congress, last summer.

It is proposed to have a permanent home for the club as soon as funds are available.

The membership list is growing rapidly. Life sustaining memberships may be purchased now by paying $250. The other memberships are:

Sustaining, $50 a year for 5 years.

Associate, $10 a year until Dec. 31 and $20 a year thereafter.

Initiation wil be $10 after the membership list begins to assume proportions.

This makes it possible for the individual salesman to get in now for $10 and enjoy a year of membership. Thereafter it will cost him $20 a year.

One of the features of the meeting was the variety of businesses represented and the caliber of the men who participated. There were big insurance companies, manufacturing concerns, food products makers and others. A few of those who bought life memberships follow as an indication of the variety of companies:

Packard Motor Car Co. of New York, General Roofing Mfg. Co., Dictaphone Co., Aetna Life Insurance Co., Computing Tabulating Recording Co., Rutherford Rubber Co., Fairchild Advertising Co., Royal Baking Powder Co., Dexter Folder Co., and L. K. Comstock & Co.

Others taking sustaining memberships were: American Fastener Co., Efficiency Engineer John M. Bruce, Cutler Hammer Mfg. Co., Union Central Life Insurance Co., Hodgman Rubber Co., Drummond Detective Agency, Matheson Lead Co., Bowman Automobile Co., Baker Linen Co., and others.

The officers of the New York club are:

President, C. Louis Allen, president of the Pyrene Mfg. Co.

First vice-president, Douglas Barnes, president of the Barnes Knitting Corp.

Second vice-president, George W.

Crouch of the Underwood Typewriter Co.

Treasurer, Oscar Coolican, New York manager of the National Cash Register Co.

Secretary, L. J. Mosness, Barnes Knitting Corp., 303 Fifth Avenue.

At last night's meeting addresses were made on salesmanship, its importance and the need for making it a science, by Norval A. Hawkins, president of the World's Salesmanship Congress and sales manager of the Ford Motor Co.; Hugh Chalmers, Chalmers Motor Co.; C. Louis Allen, Pyrene Mfg. Co.; and Edward A. Wood, president of the National Underwriters' Assn., Pittsburgh.

These men went on to-night to Philadelphia where a meeting of a new but rapidly growing club is being held. The Philadelphia club is said to be the best in the country. To date twenty-seven clubs have been formed and others are planned.

—

Harroun Plans 5-Year Contracts

DETROIT, MICH., Oct. 20—The Harroun Motors Corp. plans to make all contracts with dealers on a 5-year basis instead of the 1-year term now generally in use. The plan is to be operated because the Harroun company does not believe the short term system works to a fair advantage for dealers, since a manufacturer is enabled to transfer his line with another dealer after one year and thus causes the original dealer to lose the efforts made toward the end of the year and all sales on parts for cars he sold.

—

Elkhart and Westcott at Shows

NEW YORK CITY, Oct. 23—The Elkhart Carriage & Motor Car Co., Elkhart, Ind., will exhibit at the National show at the Grand Central Palace, Jan. 6. The Westcott Motor Car Co., Springfield, Ohio, will exhibit at the Chicago national show.

—

Plan Wheel Tax for Minnesota

ST. PAUL, MINN., Oct. 20—The supreme court of Minnesota has upheld the Duluth wheel tax law. A similar law for the State is now planned. The Twin Cities have been waiting for the decision to submit drafts for ordinances. The Duluth ordinance imposes a tax on all vehicles using city streets, the proceeds to be employed in repairing and improving the city streets.

—

Crawford Founder Dies at 70

HAGERSTOWN, MD., Oct. 13—R. S. Crawford, founder of the Crawford Automobile Co., this city, and one of the pioneer bicycle makers in this country, died yesterday in Pittsburgh at the age of seventy. He was a native of Gettysburg, Pa., and a graduate of the Mechanical Engineering School of Glasgow, Scotland.

27 Harkness Trophy Entries

—

Leading Drivers and Fastest Cars for 100-Mile Race

NEW YORK CITY, Oct. 23—Twenty-seven entries have been made for the 100-mile race for the Harkness Trophy at the Sheepshead Bay Speedway, Oct. 28. This trophy was won last year by Resta in his Peugeot in 56:55:71 or at 105.39 m.p.h. As this is practically the final speedway event of the year, the entry list will be a large one and will include all the drivers who have won places in this year's races.

There will be $12,500 in prizes, $10,000 of which will go to the first six cars to finish in the 100-mile race and $2,500 in lap prizes to the leaders of each lap after the 10th mile in a 50-mile special race for non-winners.

The list of entries to date follow:

Car	Driver	Car	Driver
Peugeot	De Palma	Crawford	Klein
Peugeot	Resta	Crawford	Chandler
Peugeot	Aitken	Crawford	D'Alene
Peugeot	Wilcox	Hoskins	Hughes
Maxwell	Rickenbacker	Hudson	Vail
Maxwell	Henderson	Ogren	Burt
Premier	Galvin	Ogren	Henning
Premier	Lewis	Adams	Adams
Duesenberg	Devlin	Benedict	Benedict
Duesenberg	Milton	Weightman	Weight'n
Duesenberg	Devore	Lenten	Lenten
Duesenberg	Buzane	Olson	McBride
Delage	Devigne	Olson	Watson
Delage	LeCain

De Palma Gets 50-Mile Record

NEW YORK CITY, Oct. 20.—Ralph De Palma was granted to-day an official 50-mile speedway record for his performance on the Omaha 1¼-mile speedway in his Mercedes racer July 15. The record for the 50 miles is 29:02.47, or a speed of 103.45 m.p.h. The previous record was held by Dario Resta in his Peugeot and was established by him June 8, 1916. Resta's time was 31:57.40. In addition to granting this record the contest board of the A. A. A. in regular session to-day reinstated driver Hirst; and refused a telegraph application of Eddie Hearne, now driving with an outlaw organization.

—

California Trucks on Desert Ramble

DETROIT, MICH., Oct. 21—Motor trucks in southern California will begin a ramble out of Los Angeles this morning. The trip is promoted by the Motor Truck Dealers' Assn., and is under A. A. A. sanction. It will last 2 days and will cover a course over the desert.

—

Weather Halts Master Driver Run

CHICAGO, ILL., Oct. 20—The second annual run for the title of master driver of the Chicago Automobile Club, which started here Oct. 19, was halted at Peoria this morning after having completed only 1 day of the 3-day drive. It was scheduled to end at Chicago on Oct. 21. Al Schiller, driving a Mercer, was the only one of the six starters to reach Peoria with a perfect score and consequently probably will be awarded the master driver title and the gold medal which were offered to the winner by Barney Oldfield.

Road and weather conditions made it necessary for the officials to curtail the event, so that instead of the 500-mile 3-day run from Chicago to Peoria, to Davenport, Iowa, to Clinton, Iowa, and return to Chicago, the 186 miles to Peoria probably will be considered the complete contest.

—

Two Races for Uniontown Speedway

UNIONTOWN, PA., Oct. 23—Sanction has been granted by the American Automobile Assn. for two races to be held on the 1⅛-mile board speedway here on Thanksgiving Day. The major race will be 112½ miles or 100 laps of the track and will be for cars of 300 cu. in. displacement or under. Prizes for this race will total $3,000, first place carrying $1,000.

A free-for-all race of 54 miles restricted to dealers residing within 150 miles of Uniontown will carry prizes totaling $1,250, first prize being $500.

—

Racing Active on Pacific Coast

LOS ANGELES, CAL., Oct. 18—Racing activities on the Pacific Coast this year will be featured by at least three events in addition to the Vanderbilt Cup and Grand Prize races on the Santa Monica course, Nov. 16 and 18.

According to plans, there will be a 200-mile championship award sweepstakes on Thanksgiving Day at the Ascot speedway with a purse of $5,000. Sanction has been applied for. Races are also planned for on both Christmas and Washington's Birthday, as well as March 17. San Francisco, Fresno and Bakersfield tracks will also hold minor events under the management of the county fairs.

—

Ross Climbs Record Hill

SAN FRANCISCO, CAL., Oct. 20—Fillmore Street hill, a grade running as high as 25½ per cent, has been climbed on high gear by a Ross eight. Never before, it is said, did a car perform that feat.

J. H. Stelling, of Arnold, Stelling & Co., Ross northern California distributors, drove the car and Ed. Rainey, executive secretary of the mayor, acted as official observer. The gear was chained and padlocked in high by L. J. Pinkson, automobile editor of the San Francisco *Chronicle*.

No Simple Test for Gasoline

Bureau of Standards Aims at Definition of Gasoline and Consumers' Protection

WASHINGTON, D. C., Oct. 20—Necessity for a careful and scientific investigation of the properties of various grades of gasoline before any standardization will be possible is emphasized in a statement issued by director Stratton of the Bureau of Standards. The impossibility of formulating a simple test which can be applied by any purchaser to detect at once an inferior gasoline is brought out as follows:

In the first place, no such simple test is known in the present state of the science of petroleum technology. In the early days of the petroleum industry, when all our gasolines, kerosenes, fuel oils, and lubricating oils were derived from one source, viz., Pennsylvania crude petroleum, a simple measurement of the specific gravity, or what amounts to the same thing, the Baumé number, by means of a hydrometer, served as a fairly reliable indication of the qualities of these products. To-day, however, the specific gravity test is practically worthless as a check on the suitability of a gasoline, for example, for a given motor equipment. The reason why this is so is that many new oil fields have been opened up in recent years that yield petroleums of very different physical and chemical properties, and new methods of manufacture have been introduced that yield products having very different properties in no way related to the specific gravities.

Work Is Complicated

It is highly probable that the specification or definition of standard gasoline, and the tests that will be necessary to determine whether the gasoline complies with the specifications, will be quite complicated and will require the services of a trained chemist to make them. It seems most probable that the definition of gasoline will have to be based on the percentage that distills over between specified temperatures, when the distillation is carried out under specified conditions, This distillation test, speaking in non-technical terms, is a measure of the freedom with which the gasoline will vaporize. The gasoline must not vaporize too freely for two reasons, one that it would not be safe, and secondly its loss in storage, by evaporation, would be too great. Hence, the specification may have to contain limitations of the percentage distilling over below a certain temperature, coupled, perhaps, with a proviso that certain percentages shall distill over below other fixed temperatures, in order that requisite amounts of low-boiling constituents shall be present to insure easy starting of an engine. Likewise the specification must contain a provision that all must distill over below a certain maximum temperature, in order to exclude from the gasoline the heavier petroleum distillates, such as kerosene.

Complicated as such a specification as has been briefly outlined above may seem to the layman, it is not at all improbable that other tests must be devised to limit the percentage of so-called aromatic and unsaturated hydrocarbons that may be permitted in a good automobile gasoline.

The question still arises whether or not it may be necessary to define two or more grades of automobile gasoline.

The message which it is particularly desired to convey is that the public should not expect hasty action.

National Legislation Possibilities

National legislation relating to interstate commerce, making it unlawful to sell a product under the name of "gasoline" that does not come within the specifications, with a suitable inspection service, would be an important contributing factor in safeguarding the consumer's interests. Other products, which might be just as good fuels for engines and carbureter equipments adapted to them, could not then be sold in interstate commerce under the name of "gasoline," but would have to be called motor fuels or by some other name which would distinguish them from the standard "gasoline." To protect the interests of the consumer in intrastate commerce it would be necessary for states and municipalities to adopt similar legislation and to increase their inspection service to provide for this new work, just as they have provided for weights and measures and pure food regulations in the past.

Molasses as Gasoline Substitute

NATAL, SOUTH AFRICA, Oct. 19—Molasses distillate is the latest gasoline substitute. That its makers are confident of its success as a fuel is assured by the recent organization of a company here under the title of South African Natalite Motor Spirit Co. with a capital of $375,000. This company is expected to build a complete plant large enough to make in the aggregate 2,000,000 gal. of natalite, as it is known, per annum and to do this at the rate of 6000 gal. a day.

Experiments were made in Natal with a 22-hp. car weighing some 3600 lb. The car was tested over several routes, the total distance covered being slightly more than 500 miles. The amount of fuel used was 30.59 gal., or an average of 16.4 m.p.g. The engine on all occasions started easily and the valve cups and valve heads were clean after the trial.

Locomotive Co. Adds Tractors

Milwaukee Concern Will Build Gasoline Truck Tractors for Freight Work

MILWAUKEE, WIS., Oct. 23—The Milwaukee Locomotive Mfg. Co., pioneer builder of gasoline locomotives, is placing on the market a new type of gasoline truck tractor. It is somewhat similar in appearance and uses to the electric industrial trucks at present in use by various large railroads. It is intended for the handling of freight at railway terminals, steamship docks and freight houses. Power is supplied by a four-cylinder, vertical, block engine with a bore and stroke of 3¾ and 4½ in., power being transmitted through a bevel gear differential and external gear-drive axle. The truck will transport 4000 lb. on its platform and will haul a trailer load of 3½ tons.

Levy Gets Chalmers Again

DETROIT, MICH., Oct. 21—The James Levy Motor Co., Chicago, has been appointed the sole distributer of Chalmers cars for Chicago and vicinity. James Levy was the original Chalmers dealer in Chicago and sold Chalmers continuously until a few months ago when the agency was given Harry Newman, Inc. Levy is one of the best known dealers in Chicago.

In addition to the Chalmers cars Levy at the present moment is distributor for Scripps-Booth, Hal, Saxon, Marion-Handley and Premier. Whether or not all of these lines will be continued has not been determined as yet.

Accessories Branch of Hardware Assn.

ATLANTIC CITY, N. J., Oct. 20—The automobile accessory jobbers in the National Hardware Assn. at the annual convention here this week formed an Automobile Accessories Branch. The chairman of the division is Edward Rose, of Barker, Rose & Clinton, hardware and accessory jobbers, Elmira, N. Y. In the hardware associations are about 400 jobbers and about twice as many manufacturers. Between 600 and 700 men attended the convention.

—

Illinois Automobile Trade Assn. Now

ROCKFORD, ILL., Oct. 18—The Illinois Automobile Trade Assn. is now the name of the Illinois Garage Owners' Assn., which closed its 2-day convention here last night. The organization will constitute the Illinois division of the National Automobile Trade Assn.

The association now has 350 members divided among ten or twelve local or-

ganizations. About 100 attended the convention, thirty of these being delegates.

The association decided to ask for a conference with the National Automobile Chamber of Commerce before formulating a standard service warranty.

Gail Reed, general sales manager, Walker Vehicle Co., Chicago, read a paper on Measured Garage Service vs. Flat Rate. He contended that the garage business is turning to the measured rate and that within another year it will be hard to find a garage charging the flat rate for service.

N. E. Jobbers to Meet Nov. 22

BOSTON, MASS., Oct. 23—The jobbing trade in New England is to be more closely affiliated with the National Assn. of Automobile Accessory Jobbers, according to the object announced for a meeting to be held in this city Nov. 22. The ways and means committee of the association is to hold a meeting here Nov. 20 and 21 and following its sessions, a general meeting of the whole New England trade will be held.

Deutsch & Bell Factory Representatives

CINCINNATI, OHIO, Oct. 23—Norman Bell, sales engineer of the motor accessory department of the Lunkenheimer Co., Cincinnati, has resigned. With S. Deutsch he has formed the firm of Deutsch & Bell with offices at 650 Woodward Avenue, Detroit. The firm will operate as factory representatives.

Studebaker Occupies New Texas Building

DETROIT, MICH., Oct. 20—The Studebaker Corp. is now occupying its new building at Fort Worth. L. B. Alford is district manager for Texas. The new structure is 150 by 265 ft., two stories high and cost $60,000.

F. H. CLARKE

Mr. Clarke is president of the Kent Motors Corp., which plans to establish a $500,000 plant in Belleville, N. J., with potential capacity for 50,000 cars a year. The line will comprise four-cylinder touring and roadster models, selling at $985

Standard Service Policy in Canada

MONTREAL, QUE., Oct. 23—A standard service policy will probably shortly be adopted in this country, following the adoption of standardization in the United States by automobile manufacturers. A standard policy has been drawn up and sent to the manufacturers for approval, and already have endorsed the policy, and its general use by manufacturers is thought to be assured. A framed copy of the policy will be hung in the salesroom so that buyers will have an opportunity of seeing just what to expect in the way of service.

K. C. Dealer's Tour Brings Sales

KANSAS CITY, MO., Oct. 23—The Motor Car Dealers Assn. made a week's tour of northeastern Kansas costing $15,000, including the expenses and time of two or more men from each of thirty-five companies and a band of fourteen pieces.

The direct result to dealers making the trip was sales of from $750 to $15,000; the indirect result will be many times that, judging from the effects in stimulation of business of previous similar trips.

Atlanta Show a Success

ATLANTA, GA., Oct. 19—A tent covering more than 34,000 sq. ft. proved inadequate to house the automobile exhibits at the Southeastern fair here this week. Thirty-five local automobile selling companies had exhibits and numerous tire and accessory concerns were represented. Southern automobile men said it was the largest display ever offered south of the Mason & Dixon line.

38 Liberty Cars in 1 Day

DETROIT, MICH., Oct. 20—Production at the plant of the Liberty Motor Car Co., this city, is increasing each day. The company reports a single day's production on Oct. 13 of thirty-eight cars. The first car built was shipped but 3 months ago on July 4.

Packard Surplus Gains $6,206,419 in Fiscal Year

(*Continued from page* 683)

ferred stock. Of the new stock issued, $4,591,630 of common stock was put out in the form of stock dividends. Proceeds from the sale of the $3,000,000 of preferred stock issued during the year provided part of the increase in working capital necessitated by the company's large expansion in business and enlargement of plant facilities.

The liabilities include $3,000,000 of 5 per cent gold debenture notes due Dec. 1, 1916. Since the close of the fiscal year arrangements have been completed for retirement of these notes and the acquisition of $2,000,000 additional working capital through the sale of $5,000,000 of 5 per cent gold notes to William A. Reid & Co., New York banker. The new notes will be dated Oct. 15, 1916, and will be due Oct. 15, 1919.

Though no statement of the company's gross sales has been included in the report, the total for the year is said to have been $35,000,000. Officers and directors were re-elected in the annual meeting and in the directors' meeting which followed it.

FINANCIAL STATEMENT OF THE PACKARD MOTOR CAR CO. FOR THE FISCAL YEAR ENDING AUGUST 31, 1916

ASSETS

Plant: Real estate, buildings, equipment and machinery at cost, less depreciation		$12,251,123.68
Rights, privileges, franchises and inventions		1.00
Inventories: Raw materials, work in process and finished vehicles		16,518,264.81
Stock option contracts with employees		138,000.00
Investments: Stocks, bonds and short time securities		533,080.94
Current: Cash		1,202,730.79
Vehicles in transit to dealers covered by drafts		527,326.66
Accounts receivable		2,040,496.01
Bills receivable		328,788.86
Expenses paid in advance		104,846.04
Total assets		$33,644,658.79

LIABILITIES

Capital stock—authorized and issued Common—total outstanding 116,569 3/10 shares of $100 each	$11,656,930.00	$11,656,930.00
Unissued 13,430 7/10 shares of $100 each.	1,343,070.00	
Total authorized issue of 130,000 shares of $100 each	$13,000,000.00	
Preferred—7 per cent cumulative—authorized and issue, 80,000 shares of $100 each		8,000,000.00
Five per cent Gold Debenture notes due Dec. 1, 1916		3,000,000.00
Deferred payments on real estate purchased for retail selling agencies		408,985.58
Notes payable		1,550,000.00
Accounts payable—current invoices, accrued payroll, vouchers not due, deposits on vehicle orders		3,182,078.83
Reserves for general purposes		465,178.34
Surplus as at Aug. 31, 1915	$4,617,297.93	
Additions this year	6,206,419.61	
Total surplus	$10,823,717.54	
Deduct dividends paid this year:		
Preferred—in cash	$455,000.00	
Common—in cash	395,601.50	
Common—in stock	4,591,630.00	
	$5,442,231.50	
Net surplus as at Aug. 31, 1916		$5,381,486.04
Total liabilities		$33,644,658.79

Prices Up

ALREADY we have seen a number of instances this year where manufacturers who lowered prices last year have put them back to their former level, or even made an increase over the 1916 model schedule. This was anticipated, and is the best possible thing for the industry, because many of the price cuts made last year were neither necessary nor good business.

At the end of 1914 the automobile industry was distinctly scared. It had planned great extensions and the general state of business looked bad for 1915 trade. So the price cuts were decided upon as an essential to the increase of production.

By the time factory extensions were completed and the new models and new prices were in force, amazing things had happened to the prosperity of the country and to the prices of raw materials, so that the manufacturers found that their extensions and their increased outputs were not enabling them to make cars as good as before with the same profit margin; in other words, the cuts had been made before a proper appreciation of the conditions. The industry is now repairing its mistake, seeing that it is far better to raise the price than to cut the quality. There is much more demand to-day for better cars than for cheaper ones, and there is every indication that this condition will persist for some time to come.

Aero Caution

THE fact that the U. S. government is buying aeronautic engines in some quantity and that Europe has been doing so for a long time has led certain of the leading automobile manufacturers to look into the business with respect to its possibilities. At present more than one of our foremost automobile engineers is giving the bulk of his time to aviation work, and next year will certainly see half a dozen good aeroplane motors ready for production in automobile plants.

When one automobile firm makes a break there is a strong tendency for all the rest to follow, but this is a situation where the greatest caution should be observed. Firstly, there is comparatively little money in the business. There will be no European orders after the war, and the U. S. air departments will not want engines in thousands. To produce a satisfactory aeroplane motor, not a good one but merely a satisfactory one, needs experimental work that can easily run to $100,000 or more, so the automobile manufacturer who adds an aviation section is likely to gain more honors than riches from his venture.

There is room next year for perhaps six, perhaps a dozen, builders of good aviation engines, but it is doubtful if there will be room for many more.

Truly Progressive Assembly

PROGRESSIVE assembly is not a new thing in itself, though it is fairly new to the automobile industry which is just finding out upon how small an output it pays to install the necessary equipment, but the equipment is only half the battle. Studying the chain assembly systems which have been put in during the last year or so makes clear the fact that some have been installed and are being run "progressively," while others are not. There is a tendency noticeable in some plants to neglect the petty detail that is life or death to the efficiency of a chain assembly line.

If the operations are not divided up properly the result will be that some jobs will be done at an extravagant waste of time, while others will not be done properly owing to lack of time. Also the feeding of a chain assembly needs as much study as the assembly itself. It is little use assembling a part in 10 sec. if 5 min. are wasted in bringing it to the desired spot first. In most of the recent installations there is room for improving the supply of parts to the assembly line and in many bad work is getting past owing to an inefficient splitting up of the time into its various sections. The hospital section at the end of the line where the assembly shortcomings are corrected is often kept pretty busy, and the need for it is a confession that there is something wrong with the assembly itself. Time will effect a cure, of course, but there is at present so surprising a difference between factories that it seems insufficient knowledge is being circulated.

It will pay our manufacturers to look into this detail of operation and perhaps some changes may be made to advantage in the layout of the system.

URUGUAY

One of the main streets in Montevideo, showing the double line of modern trolley cars with ample room on each side for two rows of motor traffic abreast. The streets are generally well paved. While Montevideo has several narrow Spanish type streets in the older sections of the city, there are many of these wide modern streets. The city is the great tourist center for the east coast. Because of this there are many good hotels for tourist trade, good city and beach motor drives, in fact there is no other city in South America so ambitious for automobile trade as Montevideo

By David Beecroft

¶ EDITOR'S NOTE:—This is the first of a series of articles embodying the close observations of automobile and general trade conditions in Uruguay made by Mr. Beecroft, Directing Editor of THE AUTOMOBILE, during a 10-weeks' trip through Argentina, Uruguay and Southern Brazil as a delegate of the United States Government and member of the Argentine Return Visit Committee. Subsequent articles will further analyze the possibilities of selling cars, trucks, tractors and accessories in Uruguay.

ALTHOUGH the smallest country in South America, Uruguay is of much greater importance to the motor industry than its area or its population would lead you to believe. Uruguay as a country equal in area to the six New England States, with New Jersey added, and measuring only 355 miles from north to south, occupies a position in South America similar to Belgium. As Belgium was the buffer State between Germany and France, so Uruguay is a buffer country between Brazil, to the north and east and Argentina. Brazil and Argentina are great rivals. Their navies are approximately of equal strength. When one adds a large battleship the other follows suit. They watch army figures; in fact, the development of one is always carefully watched by the other.

Uruguay, like other South American countries, is not a manufacturing country, although it is perhaps a leader in this regard. It does not manufacture anything for the automobile or motor truck business and is of interest to us only as a consumer market.

Car and Truck Field Small

With the population of only 1,300,000, not so much as the city of Buenos Aires alone, there is naturally a limited automobile and motor truck market. Australia has a population of 5,000,000 which is a high potential buying population. Canada has a population of 8,000,000, which is also a high potential buying population. Argentina, with a population of 8,000,000, is not so potential a buying population as Canada. Brazil with 25,000,000 has a still lower potential buying factor. It is questionable if Uruguay with its 1,300,000 has not a higher potential buying factor than any other South American country.

Imported 183 Cars in 1915

At present it is almost impossible to get a correct estimate on the number of automobiles in this country. The old reliable dealers differ in their estimates, and as there is no registration for the entire country, but only in departments, it is impossible to get up-to-date reports. One dealer estimates from 3500 to 3800 cars in the country. Another equally reliable dealer places the figure at 3000 to 6000. All agree that there are scarcely 100 motor trucks in the country.

During 1915 a total of 183 automobiles were imported into Uruguay, according to the figures of Herman L. Spahr, American consul at Montevideo, the capital city. In addition there were fifteen motorcycles and forty-six bicycles. Our

U. S. consular reports show that in 1914 we shipped from the U. S. A. 183 automobiles and one truck to Uruguay. The figures for 1916 are not yet available.

Montevideo the Center

In the capital city, Montevideo, with a population of 375,000, the automobile industry for the entire country centers. Montevideo is one of the most modern cities in South America, being the only one at present supporting a motor bus line on its city streets in addition to an up-to-date trolley system. The motor buses are similar to those operated by the Fifth Avenue Bus Co., New York City. The city of Montevideo is essentially a rolling city built on and around a series of reasonably low hills, and has an excellent water frontage on the ocean. It is 104 miles from Buenos Aires by boat.

Here in this city you find as modern automobile salesrooms, garages, etc., as in Buenos Aires, but of course on a smaller scale, much in the ratio of the population of the two cities. Here on the streets you see long lines of European cars of the closed type, the same as in all South American cities. There are rows of taxicabs along the sides of the city plazas and the streets are generally well paved. Montevideo has the advantage also, as an automobile city, of having several very modern macadam highways radiating out of the city. There is no other city in South America with the possible exception of Cordoba, in the heart of Argentina, where such excellent motoring roads exist. The national government of Uruguay has been building a series of national roads for some years and to-day Uruguay, although the smallest country in South America, has more modern automobile highways than any other country on the continent. It has more modern highways than Brazil, which in area equals the U. S. A. It has more modern highways than Argentina, which in area equals the U. S. A. east of the Mississippi River.

In Montevideo you find salesrooms just as modern in some cases as on Broadway, N. Y., or Michigan Avenue, Chicago, although not so elaborate. They remind you of the salesrooms in cities of the Mississippi Valley. Here you find such U. S. A. cars as Overland, Ford, Studebaker, Chevrolet, Hudson, Buick, Haynes, King, Scripps-Booth, Dodge, Maxwell, and others. Very frequently they are sold in salesrooms all their own, but in other cases are alongside of expensive European cars that have not been selling for 2 or 3 years.

Statistics Are Meager

It is almost impossible to get a definite idea of the number of different makes of U. S. A. cars that have been sold in Uruguay. A canvass of the different dealers furnished information as follows: There have been approximately 800 Fords sold in the country, and last June the local dealer in Montevideo was 7 months behind in deliveries. The Ford dealer employs two traveling men who are constantly going throughout the country. In 1915, there were 180 Fords sold, and it is expected that in 1916, some 280 or 300 will be marketed in that country. In addition to the head office in Montevideo there are nine Ford sub-dealers throughout the country. Over 90 per cent of the Fords are sold in the country districts.

Studebaker has perhaps one of the best salesrooms in Montevideo and from it the entire country is served. Upward of 100 Studebakers were reported in Uruguay in June. Seventy-five per cent of these have been sold to the farmers, or camp people as they term them in Uruguay. In addition to the Montevideo salesroom there are ten other Studebaker dealers throughout the country.

Reports show approximately 75 Buicks in Uruguay and two dealers in addition to the representation in Montevideo. Over 75 per cent of the Buicks have been sold in the camp, or country.

Information which was collected in the circuit of the dealers at Montevideo estimated the following numbers of other cars in the country: Chevrolets, forty-six; King, eight; Pierce, four; Haynes, five; R. C. H., six; Case, fifteen; Overland, 100; and Dodge, twenty-five. There were other makes on which it was impossible to get figures.

Camp the Main Market

It is the general consensus of opinion that the great percentage of U. S. A. automobiles will have to be sold in the camp. Dealers agree that over 75 per cent are already sold in the camps and that the cities of which there are very few outside of Montevideo are stocked with European cars. The development of the U. S. A. automobile in Uruguay is thus destined to follow the same lines of introduction as in Argentina, Brazil, and other South American countries, namely, from the country or camp to the city.

The country of Uruguay is essentially a rolling pampa, almost treeless. It is not level like Argentina, but constantly rolling and getting rugged as the northern part is approached.. The country lacks population, as the figures of 1,300,000 for a territory as large as New England with New Jersey added, would indicate. Naturally the population centers around the south and up the west coast along the Parana River. In the country are 25,000 estancieros or farmers. It is to this class that the Montevideo dealers are selling automobiles to-day. These estancieros make Montevideo their business headquarters, which naturally allows the automobile dealers an opportunity of demonstrating their cars and closing sales. When the car is delivered the dealer sends a driver to make delivery to the home of the estancerio. It may require 1 or 2 days to reach his home, as the roads are deplorable in wet weather when you get off the modern system of highways radiating out of the capital.

500 Cars in Soriano

There are several departments, or we might call them States, in Uruguay, which are good purchasers of automobiles. One of the richest of these is Soriano, the capital of which is Mercedes. It is estimated that there are 500 cars in this department. The department of Salto, further north, has 250 cars. These are the two most important departments, but in the others there is a good scattering of motor cars. The buying population of these interior towns and cities can scarcely be estimated from population figures. Very frequently the majority of the wealthy farmers will live in these cities, thus greatly increasing their potential buying capacity. The population of some of the cities of the country follows:

Paysandu	35,000
Mercedes	25,000
Salto	25,000
Fray Bentos	15,000
Rivera	10,000
Guadalupe	10 000
Minas	10,000
Florida	10,000
Colonia	10,000

The people of Uruguay look favorably upon the U. S. A. automobile industry largely because a good deal of U. S. A. money is being invested in the country and also because large U. S. A. firms are fulfilling contracts of one nature or another in Uruguay. This work has naturally been facilitated by a branch of the National City Bank in Montevideo. This bank contains a large credit department, as do the other branches of this bank in South America. U. S. A. automobile manufacturers can get any information desired regarding credit of dealers or others through this bank. The manager hails from Texas and has had years of experience in U. S. A. and is consequently well qualified to give whatever information the automobile manufacturer requires. He has been particularly active in interesting Montevideo dealers in U. S. A. automobiles and one of the recent agencies which he was directly responsible for negotiating is proving very successful. The bank is interested in this work and the

Glimpses of Farm and Factory in Uruguay

Upper—General view of the treeless pampas which stretch for miles upon miles of rolling country in Uruguay. The large estancia or farmhouse in the foreground is the property of a French company. This view is taken in Florida, one of the states in Uruguay

Middle—One of the large packing houses in Montevideo, the capital city of the Republic of Uruguay. Establishments such as this are operated by Swift or Morris & Co. and other big packing firms

Lower—View of the sugar factory of La Sierra, one of the leading industries in the State of Maldonado, one of the departments, or states, of Uruguay. Note the peculiar flat cars on the railroad siding

General view of country adjacent to Montevideo, Uruguay. It is essentially rolling and treeless in a large percentage. Naturally, where settlements have been made trees have been planted, which give the country an attractive appearance. The home of the estancerio is shown, but unfortunately for each estancerio there are scores of mud huts the same as in Argentina

manufacturers should not hesitate getting all information desired.

Several large U. S. A. firms are operating in Montevideo. McArthur Bros., large railroad construction people, have $12,000,000 contracts. The Uhlen Co. is doing much municipal improvement work in Paysandu, Mercedes, Salto, and other interior cities. Other firms have similar construction work. In Montevideo are large packing houses, one controlled by Swift of Chicago, and the other by Morris and Armour interests. Thus U. S. A. manufacturers are not foreign to Uruguayans. They are already familiar with our large corporations and our methods of doing business.

In the accessory field the business in Uruguay is largely the same as in any other South American country. Where our cars are sold there is a demand for accessories. Montevideo has one very large modern accessory and supply house which distributes to the entire country. In addition the garages carry lines of accessories, parts, etc., much as in Argentina and Brazil. Our largest tire concerns are nearly all represented in Montevideo. Some of them are handled through agencies and others through dealers appointed from Buenos Aires. There is a good demand for U. S. A. tires, largely due to the inability to get tires from Europe, with the possible exception of Italy.

High freight rates constitute one of the drawbacks to the automobile business in Uruguay. Freight rates from New York to Montevideo are practically the same as from New York to Buenos Aires. In June it was costing $130 ocean freight from New York to Montevideo on a Ford. Some of the Chevrolets were shipped at $1.05 per cubic foot. It was costing $200 to send an Overland Model 75 from Toledo to Montevideo.

Because of these high freight rates, to which must be added the import tax 31 per cent ad valorem prices on cars are much higher than in U. S. A. The Ford sells for $850, Uruguay currency. Uruguay is the only country in South America where a dollar is worth less than the U. S. A. dollar. They will only allow you approximately 95 cents Uruguay coin for a U. S. A. dollar, so that the price of $850 means considerably more in our currency.

The duty on tires entering Uruguay is largely based on tire value. Thus a tire is valued at $10 and the duty is $4.50 U. S. A. gold. A tube is valued at $5 and pays a duty of 45 per cent, which is $2.25 U. S. A. gold. A steel-studded tire is valued at $15 and paying a 45 per cent duty means $6.75 U. S. A. gold duty. There is no duty on tires shipped into the country on a car, so naturally all Montevideo dealers purchase cars equipped with a set of five tires. Tire chains are used in Montevideo much the same as in any U. S. A. city.

Uruguay's Highways

Uruguay aims to be the leading pleasure-ground for the countries of South America and with that end in view has given great attention to the development of its roads.

These ambitions are not day-dreams, and they are fast becoming realities. To-day Uruguay has more improved highways for motoring than Argentina, Brazil, Chile or any other South American country. So far is her great dream of being the Riviera beneath the Southern Cross already realized. The wealthy Argentines ship their motor cars by boats, a night's trip of 90 miles, from Buenos Aires to Montevideo to enjoy the fine system of roads now under construction by the Uruguayan national government. Brazil's wealth also seeks the highways of Uruguay for recreation and motoring joys.

Further details of Uruguay's highway development will be taken up in a future issue.

S. A. E. Standards Committee Widens Scope

THE meeting of the Standards Committee at Washington last week seems, when its results are analyzed, to have added very little to the recommended practice of the society. This undoubtedly is correct, but there are a number of very vital subjects which have previously been matters for very vigorous discussion and which are now brought for the first time within definite sight of final agreement.

A Trial Scheduled

The first of these is the fuel economy and acceleration testing schedule on which the research division has been working for nearly 2 years. This has been before the committee many times and has constantly been referred back to the division. It has now been provisionally accepted by the committee and a trial is to be made on the Sheepshead Bay speedway to check up the working of the system, so that the absolutely final documents may be placed before the winter meeting of the society.

The research division also reported that it had reached the conclusion that no simple formula for stating the ability of a car in mathematical terms could be devised, owing to the very large number of factors which enter into and affect the indefinable thing usually described as car performance. While a formula can deal with piston displacement, gear ratio, etc., it cannot express the delicacy of the springs, softness of the upholstery or the easy control which, together with many other similar matters, are of great importance in giving a car its character.

The acceptance of the testing form in January will clean the slate of the research division which will then have nothing left before it until some new assignment is made by the Council.

Aeroplanes Not Easy to Standardize

With Henry Souther as its chairman, a good deal of activity was naturally expected from the aeronautical division. This presented a report and suggested the fact that this division had done more actual work during the Summer months than any other committee.

The aeronautic position is a somewhat peculiar one because the science of aeroplanes and aeroplane engine building is developing so rapidly that some new thing appears every day. This means that if any standards adopted in the light of the best knowledge which we possess to-day, then 6 months hence we may find it essential to change those standards. On the other hand, the need of standards is very great. One of the speakers in the discussion said there were in Europe as many different methods of attaching propellers to their hubs as there had been chief engineers in the outgoing industry. The adoption of the standard hub and propeller mounting will mean that the U. S. Government will order its supplies accordingly. This will mean that everyone doing government work will use the S. A. E. standard hub, and if any change is found desirable 6 months or a year hence everyone will have to change and the inconvenience will be no greater for one manufacturer than for another.

Supposing two different standards are used during a single year. At the end of that year the government will have to carry stock for the old and the new standard. In other words, for two series of sizes, probably about six sizes in all. If, on the other hand, they use no standard at the end of the year they may have to carry sixty sizes or more. Thus it is obvious that it is well worth while setting up a standard even if this be in use only for a brief time.

Truck Standards Valuable

Regarding the military truck specifications on which the truck standards division is working, the situation is extremely satisfactory. The quartermaster's department of the army is engaged upon an examination of the evidence derived from the trucks in use on the border and from some informal discussions which took place during the Washington meeting, it is obvious that the work of the truck standards division is going to be very valuable. There is some need for speed, and it is hoped that the S. A. E. ideal specification may be agreed upon completely during the Winter.

With the establishment of a special small committee to deal with, the electrical equipment division has one of the most troublesome subjects taken from its program, although this still leaves it plenty to do. The elaboration of the generator and starting motor mounting standards is the principal item. This should be in final form by January.

Practical Engine Rating

Errors in Developing Rating Formula and Incorrect Use of Piston Speed—Variation in Power Efficiency with Different Sized Cylinders*

By Edward G. Ingram

ALMOST from the birth of the automobile industry the development of a suitable horsepower rating formula has been a subject of discussion, though of late it has not received so much attention.

One of the first real investigations on this subject was made by the horsepower committee of the Institution of Automobile Engineers, in Great Britain, yet the results were not satisfactory. The committee set out to find a formula that would give the approximate horsepower of engines from a knowledge of the bore, stroke and number of cylinders. For obvious reasons, nothing more than a general idea of the horsepower that various makes of engines will develop can be obtained from these dimensions alone, but the error that the committee made in deriving a formula was that it attempted to make use of piston speed instead of the frequency ("speed") of revolution. It is practically impossible to use piston speed in developing a rating formula, for several reasons.

Piston Speed Wrong Basis

To illustrate why this is, let it be assumed temporarily that all engines have the same volumetric and thermal efficiency. Then maximum power will be obtained at the same number of revolutions per minute in all cases, no matter what the stroke-bore ratio or piston displacement of the engine may be. Under the same conditions, however, the piston speed at maximum power will not be the same for two reasons:

1. Because in engines of the same piston displacement the piston speed will vary with the stroke-bore ratio.

2. Because even if all engines had the same stroke-bore ratio the piston speed would vary with the displacement, or in other words the size, of the engine in each case.

Of course, actually, the thermal and volumetric efficiency will vary considerably with the design of the engine and this will cause some variation in the revolutions per minute at maximum power, and a further variation in the piston speed. However, since but two factors affect revolutions per minute while four affect the piston speed, it is obvious that the speed of revolution and not the linear piston speed should be considered in developing a horsepower formula.

The brake horsepower of a four-cycle engine in terms of the revolutions per minute is equal to the following value:

$$(1) \qquad \frac{Nn\pi b^2 l \eta p}{3{,}168{,}000}$$

Where N equals the number of cylinders,
n " " revolutions per minute
b " " bore
l " " stroke
Where η equals the mechanical efficiency,
p " " m. e. p.

Here n, η and p are the unknown quantities, approximate values for which must be determined by obtaining the average figures from the performance of actual engines.

The linear piston speed s equals

$$\frac{2nl}{12} = \frac{nl}{6} \text{ feet per minute}$$

Substituting this value in (1) and incorporating the value of π in the constant, the brake horsepower in terms of the piston speed is

$$(2) \qquad \frac{N s b^2 \eta p}{168{,}000}$$

This second formula was the one used by the British horsepower committee in their investigation. It necessitated the determination of the piston-speed in ft. per min. at maximum output instead of the r. p. m. While the formula is satisfactory when the piston speed is already known, as in the case of an engine under actual test, it is practically useless where the piston speed is unknown and must be determined for engines of various displacements and stroke-bore ratios.

In its attempt to find the piston speed at maximum power of engines of different stroke-bore ratio, the British Committee made tests on 101 engines, after which it decided that it would be represented by the equation $s = 600\ (r + 1)$ feet per minute, which gives a piston speed of 1200 ft. per minute when $r = 1$, and 1800 feet per minute when $r = 2$. This was a most remarkable decision because the formula gives excessively different speeds of revolutions to engines having the same stroke-bore ratio but different displacements.

For example, a 3 by 3-in. engine according to this formula would develop its maximum power at 2400 r. p. m. while a 6 by 6-in. engine would reach maximum power at 1200 r. p. m. Again, assuming equal efficiency in engines of the same displacement, maximum power should be reached at the same

*The curves and figures illustrated and mentioned in this article have been taken from data published from time to time and do not necessarily refer to the latest models of the various makes.

number of r. p. m. no matter what the stroke-bore ratio, yet the piston speed given by the formula will give different speeds of revolution with engines of different stroke-bore ratios.

Effect of Cylinder Size

Because small cylinders have a greater proportion of cylinder surface to volume than large cylinders, resulting in greater heat losses through the water jacket, the British committee decided that the m. e. p. would vary with the size of the cylinder. It has since been shown, however, that in practice this is to a great extent made up for by the use of a higher compression in engines with small cylinders, so that the average m. e. p. is more nearly the same for cylinders of all sizes. One reason the committee went astray on the question was because in making tests they considered the variation in m. e. p. with relation to the bore instead of the piston displacement.

It is obvious therefore that, if the average number of r. p. m. had been considered instead of the piston speed and, if the average m. e. p. with relation to the piston displacement had been determined, the committee would have obtained a much more satisfactory formula than the one arrived at, which was,

Brake Horsepower $= 0.45(b - 1.18)\ (1 + b)$

It would appear, however, that a great deal of unnecessary labor is gone through in trying to develop a horsepower rating formula by making use of the formula for obtaining the brake horsepower of an engine under actual test, and then attempting to arrive at average figures for the unknown factors such as the m.e.p. and r.p.m.

TABLE II—RACING CAR ENGINES

Engine (all fours)	Bore and Stroke	Max. Hp.	R.p.m.	Pis-ton Disp.	Disp. Per Cyl.	Hp. Per Cu. In. of Disp.

Average Power

Just as satisfactory results can be obtained by finding the horsepower that the average engine may be expected to develop per cubic inch of piston displacement.

The only thing that then enters into the question is whether engines with small cylinders will develop the same horsepower per cubic inch of displacement as engines with large cylinders. Experience in both the standard and racing car field indicates that the small cylinder engine is more efficient and will develop a higher amount of horsepower per cubic inch of displacement. This probably can be explained by the fact that while the thermal efficiency of a small cylinder may be lower, even with the use of a higher compression, this is more than offset by the fact that much greater valve area with relation to the displacement can be obtained, resulting in a higher volumetric efficiency. Increased volumetric efficiency means not only a higher speed of revolution, but also a higher m. e. p. at a given number of r. p. m.

To give some idea of the brake horsepower per cubic inch of displacement, which standard engines of up-to-date design will develop, Table I has been compiled, and in Fig. 1

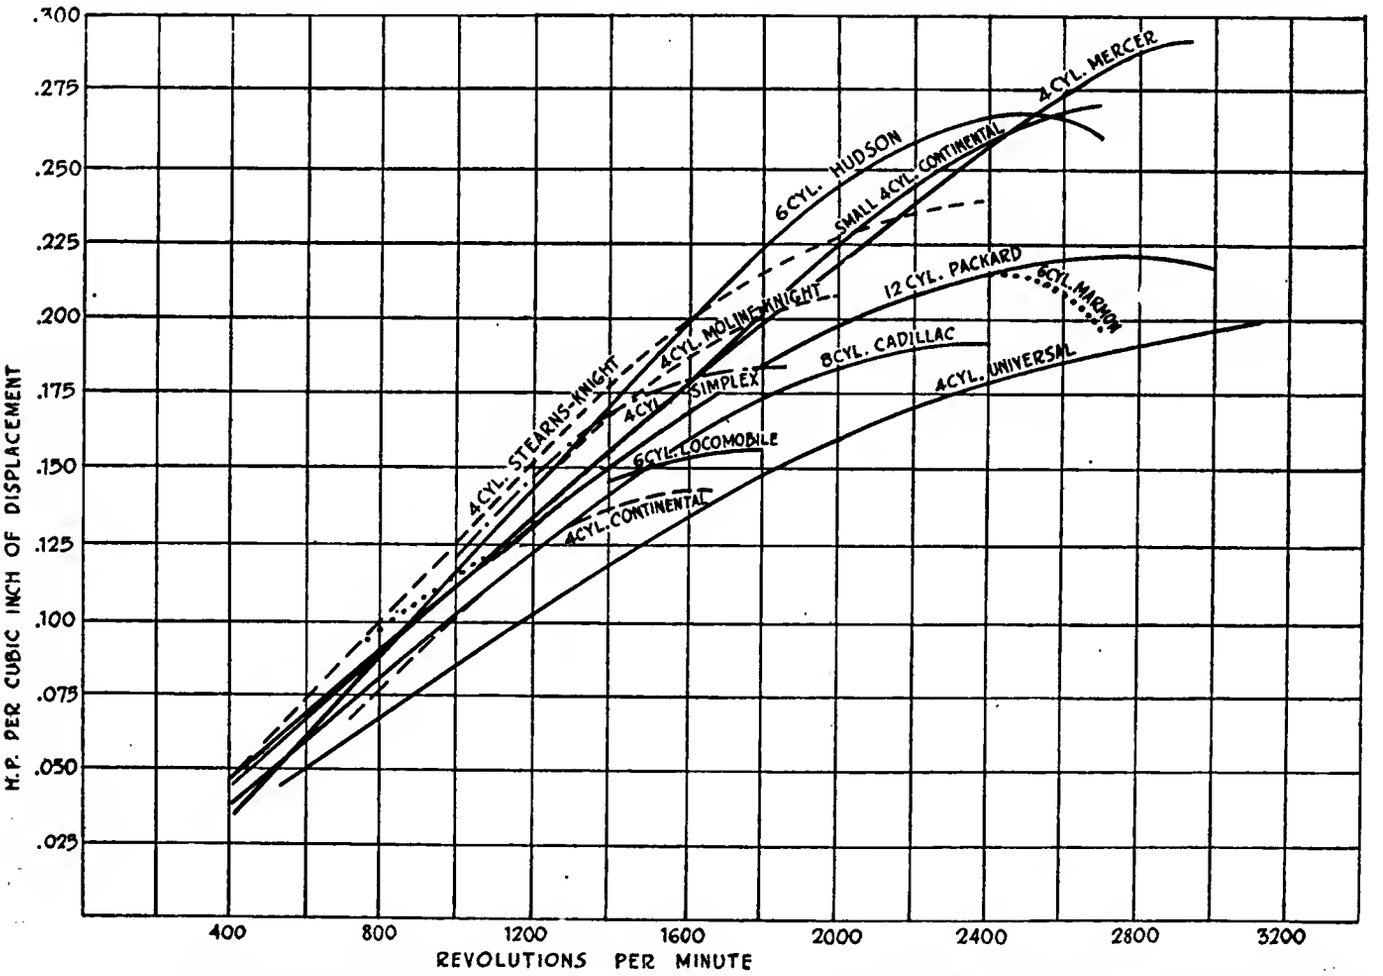

Fig. 1—Curves showing the horsepower per cubic inch of displacement at various speeds of several makes of stock car engines

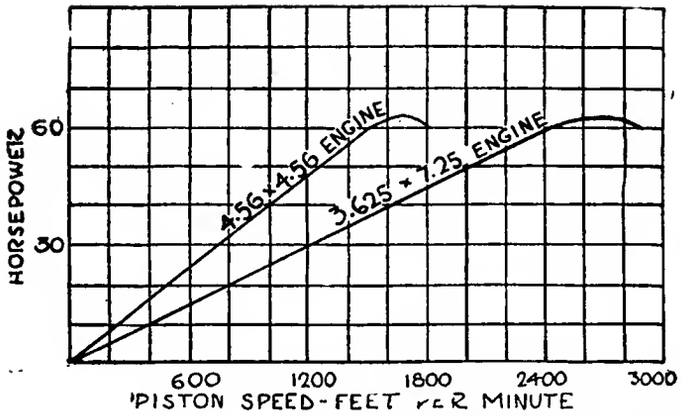

Fig. 2—Imaginary power curves plotted against piston speed

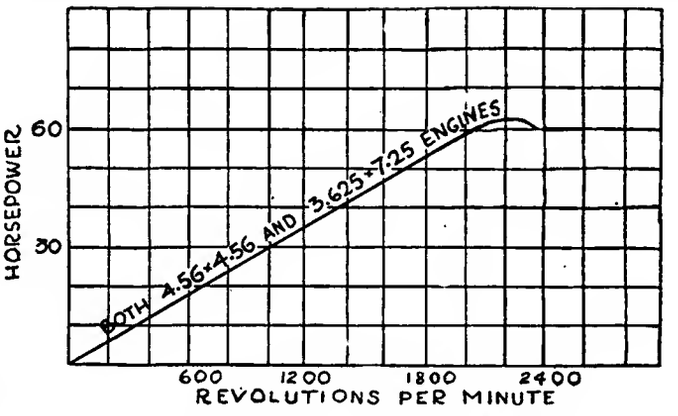

Fig. 3—Curve of engines in Fig. 2 plotted against r.p.m.

are shown power curves of some of these engines, plotted on the basis of horsepower per cubic inch of piston displacement. Outside of their value in determining a means of rating engines the figures are interesting, for this also is about the only satisfactory way of obtaining an idea of the relative power efficiency of engines of different displacements. The curves show not only the relative efficiency at maximum output but also at lower engine speeds.

It must be remembered, however, that because one make of engine is more efficient than another this does not mean necessarily that the performance of the car in which it is used will be better, since this depends upon the total displacement of the engine, weight of the car and many other considerations. Some designers prefer to use large slow-speed engines of relatively low efficiency instead of the high-speed type.

In speaking of power curves attention here may be called to the fact that it is much better to plot the horsepower against r. p. m. instead of against piston speed in feet per minute. For example in Fig. 2 is shown imaginary power curves of two engines of the same displacement but with different stroke-bore ratios plotted against piston speed. The engines are assumed to be of the same general construction so that the power developed will be essentially the same at any given number of r. p. m. up to the maximum. At any point where both engines are developing the same amount of power the piston speed will be different, so that the curves will never coincide. If, however, the curves are plotted against r. p. m. one curve will represent both engines, as shown in Fig. 3.

If the two engines were placed in identical cars, the same gear ratio should be used for both and the cars would make the same number of m. p. h. when the engines were developing the same power. The piston speed, however, would bear no direct relation to the engine output or to the car speed but would depend upon the stroke-bore ratio. Comparing engines on the basis of horsepower per cubic inch of displacement is really the same as considering each to be of the same total displacement no matter what is the real displacement.

Comparing Different Engines

In looking over Table I and the power curves in Fig. 1 the first thing to attract attention is the wide variation in the power per cubic inch of displacement developed by various makes of engines. The highest curve is that of a four-cylinder Mercer. This engine develops 0.292 hp. per cubic inch of displacement, which is over twice as much as that developed by the four-cylinder slow speed Continental engine, the curve of which is the lowest of all. The displacement per cylinder of these engines is 74.5 cu. in. and 70.1 cu. in. respectively.

Next to the Mercer in power efficiency comes a small high-

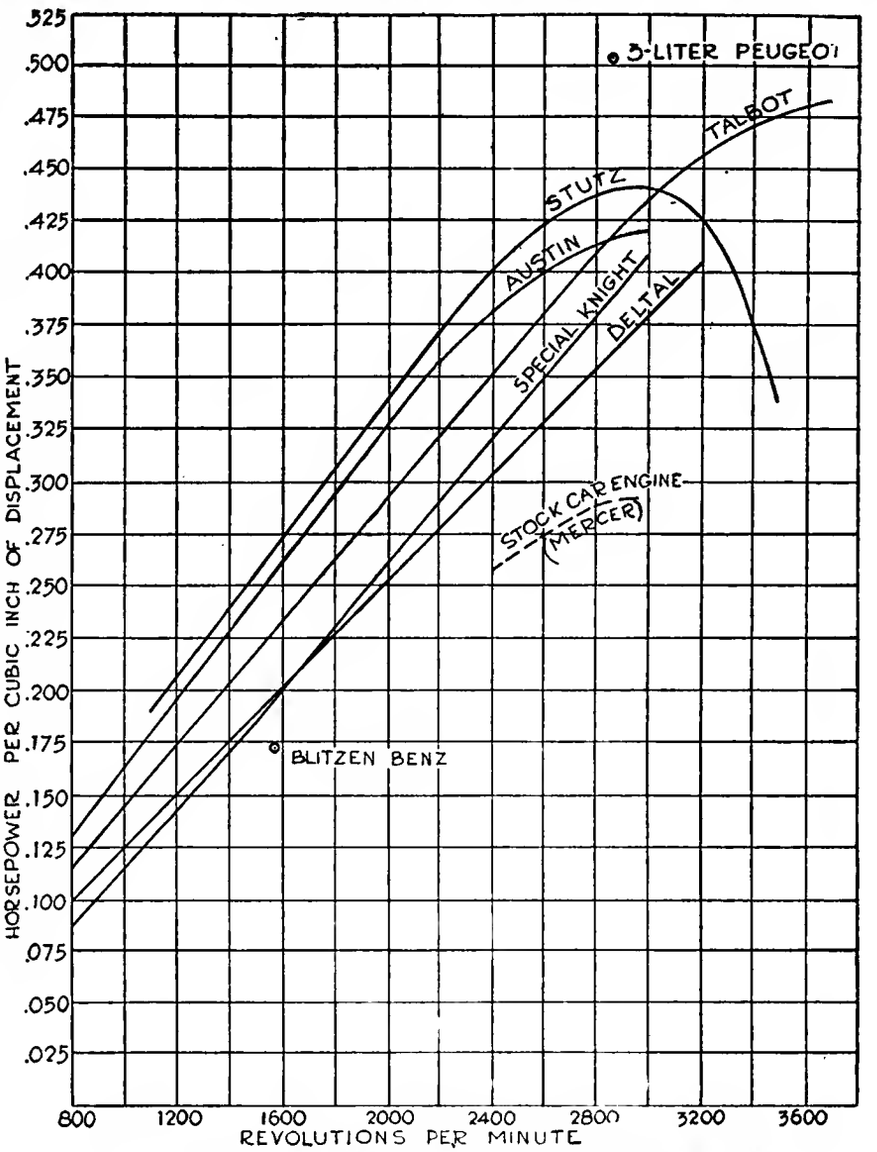

Fig. 4—Curves showing the horsepower per cubic inch of displacement at various speeds of several makes of racing car engines

speed Continental engine with a displacement per cylinder of only 23.7 cu. in., and closely following this comes the Hudson super-six engine with cylinders of 48.1 cu. in. displacement. Even though there is considerable variation in the power efficiency of engines of about the same displacement per cylinder, due to variations in design, still the tendency for engines with large cylinders to be less efficient is shown, though it is more marked in the case of cylinders of over 74 cu. in. displacement.

The large Simplex engine, for example, with a displacement per cylinder of 147.8 cu. in. is designed along very efficient lines yet its power per cu. in. of displacement is only 0.183. The average hp. per cu. in. of displacement developed by the eleven engines in Table I with cylinders of under 40 cu. in. displacement is 0.215, while the five engines with cylinders of over 80 cu. in. displacement show an average power efficiency of only 0.171.

While engines with large cylinders are less efficient at high speeds of revolution, there appears to be a tendency for them to be more efficient at low speeds. For example the Simplex curve is the highest of any of the poppet valve engine curves at 1000 r. p. m., while the curve of the little Universal engine with cylinders of only 17.2 cu. in. displacement is the lowest at this speed. Its maximum power efficiency, however, is higher than that of the Simplex engine. This tendency for large cylinders to be more efficient at low speeds of revolution may be due to the better thermal efficiency already spoken of, though just why this should be more apparent at low speeds is not altogether clear.

There is apparently a tendency for the small cylinder engine to develop maximum power at a very high speed of revolutions. The little Universal engine, for example, gives its maximum output at 3200 r. p. m., while the large Simplex engine develops maximum power at about 1800 r. p. m. Most of the other small cylinder engines develop maximum power at high rotative speeds. This seems consistent since the small cylinder is better off with regard to volumetric efficiency. The average number of r. p. m. for the engines in Table I with cylinders under 40 cu. in. displacement is 2545, and for engines over 80 cu. in. 1800.

Knight Engine Characteristics

A characteristic of the Knight stock car engines is high-power efficiency at low revolution speed even where the cylinders are small. The Moline-Knight curve is higher than most others at 1000 r. p. m. though the displacement per cylinder is only 48.1 cu. in. The curve of the Stearns-Knight is the highest of all at 1000 r. p. m. Maximum power also is reached at rather low speed compared to the poppet-valve engines. This may be due partly to higher thermal efficiency and partly to better volumetric efficiency within the engines' speed range. Of course, none of these tendencies always hold good, but this hardly is to be expected considering the many variations in individual engine design. For instance, both the Mercer and Hudson companies have been prominent in racing and have developed their stock car engines along exceptionally efficient lines. The power developed by these two engines therefore is abnormally high. Variations in valve timing undoubtedly make comparisons of the different makes of engines much more difficult. The Hudson curve, for example, is remarkably high at high speeds of revolution and quite low at low speeds. This probably indicates that the valve timing is such as to favor high maximum revolutions at the expense of a slight loss in efficiency at low speeds.

Much more convincing evidence of the fact that small cylinder engines show higher power per cubic inch of displacement is to be found in an investigation of racing car engines. This is because maximum power always is aimed at in racing practice while other considerations affect the design of standard car engines. In Table II is given the power efficiency of some typical racing engines of various cylinder sizes, and in Fig. 4 are shown power curves of some of these engines plotted on the basis of horsepower per cu. in. of displacement.

At the head of the table is the 3-liter Peugeot engine, which is probably the most efficient engine yet produced, its output being over 0.5 hp. per cu. in. of displacement. The cylinders of this engine have a displacement of 45.7 cu. in., and comparing this with the large Peugeot engine, which has cylinders with a displacement of 114 cu. in., it will be seen that the output of the larger engine is only 0.384 hp. per cu. in., that is the smaller engine is about 31 per cent more efficient. This comparison is particularly satisfactory because the two engines are of almost identical design throughout, both having four overhead valves per cylinder.

Perhaps even more convincing is a comparison of the 3-liter Peugeot engine with the huge engine of the Blitzen Benz. The Benz engine has cylinders with a displacement of 327.5 cu. in., and is built along very efficient lines, yet its output is only 0.183 hp. per cubic inch of displacement, which is lower than many touring car engines and only about one-third that of the 3-liter Peugeot. Maximum power is developed by the little Peugeot at 2870 r. p. m. and by the Benz at only 1575 r. p. m. A remarkable curve is that of the Talbot engine, which is of L-head construction with but two valves per cylinder. The cylinders have a displacement of 69.1 cu. in. and the hp. per cu. in. of displacement is 0.482, which is very high indeed.

To determine the variation in the power per cu. in. of displacement developed by engines with different sized cylinders would require extensive tests made on engines of otherwise similar design, and would tend toward a more complicated rating formula. Also while the variation is considerable in the case of racing car engines of widely different cylinder sizes, it is not so great in stock car engines, being less in fact than that due to differences in individual design. A very fair idea of the maximum power developed by the average touring car engine of to-day can be obtained by multiplying the total piston displacement by 0.17. True, many efficient small cylinder engines will give much greater power than this while very large cylinder engines or engines of inefficient construction may fall below this output; but the rule will give much more satisfactory results than those obtained from the rating formula now in general use.

—

Valve Sizes Need Definition

FOR the past few years the magic words, "big valves," have been used as an attractive bait by the car salesman among his array of talking points. In fact, the words have not been infrequent at engineering discussions, and furthermore, since they deal with one of the developments of modern engines, it would be very advisable if they were made a little more clear. The way matters are at present when the engine manufacturer states that his valves have a diameter of a certain number of inches, no one can be quite certain as to what is meant.

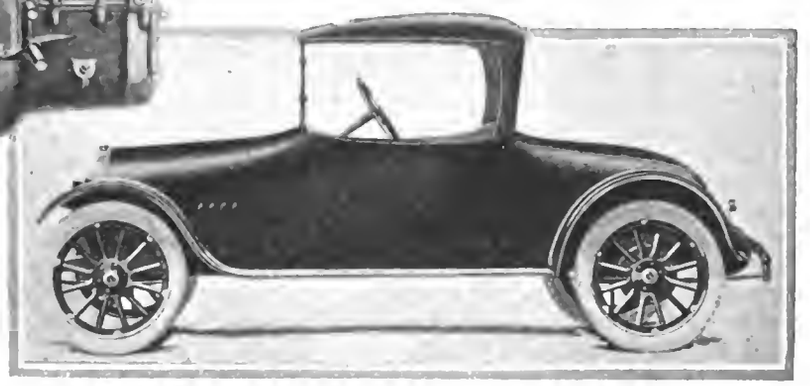
In the first place the so-called in-the-clear dimension means nothing unless the diameter of the valve stem is also given, as naturally it is only a matter of clear area. It would be far more to the point to give the area with the section area of the stem subtracted, as then a clear basis of comparison is given.

The class of purchasers of automobiles who are sufficiently educated to go into such technical points as valve sizes certainly is increasing. It therefore becomes increasingly necessary to make the information clear and definite instead of misleading. Information of this kind should be given correctly or not at all, and, as it is important and worth giving, a standard should be fixed so that a valve dimension will mean a definite thing applicable to all engines.

New Oakland Is More Powerful

Engine Output Increased 6 Hp. Without Changing Cylinder Dimensions—Body 6 In. Longer —Eight Continued Unchanged

Left side of new Oakland 34 engine, showing mounting of carbureter



The new Oakland coupé with the side panels removed

BY the substitution of a new body and a number of detailed mechanical changes the Oakland car for 1917 is made a roomier, easier riding and more powerful vehicle than its predecessors. Owing to the new body, the appearance is changed to a large extent and immediately gives the impression of being a much larger car throughout.

It is difficult to compare the present body with that of the 1916 model as the shape has been materially altered. It is 6 in. longer and of this, 5 in. has been taken up by increasing the depth of the tonneau and the other inch in enlarging the front compartment. In addition to the body change, the radiator is entirely new, being made with a deeper shell and a flat instead of a rounded front, so that although a number of indefinable features immediately proclaim the car to be an Oakland, the general appearance is in many respects different. The present model is known as the 34, and it is a refined and enlarged continuation of model 32. Model 50, the eight-cylinder car, is continued without change.

4 In. More Overhang in Rear

Although 6 in. has been added to the body, the wheelbase has been increased but 2 in., from 110 to 112, and the additional body space has been secured by giving 4 in. more overhang in the rear. To take care of the large proportions, 32 by 4 tires are new fitted all around in place of 32 by 3½, although, as far as the weight of the car is concerned, the 3½ size is sufficient, thus giving an over-tired car. This should make for tire economy.

Easier riding has been secured through an alteration of the spring suspension. The rear springs are now semi-elliptic in place of the three-quarter-elliptic and are 51 in. in length, whereas the three-quarter-elliptic had a length of 40 in. In changing the spring suspension, the use of Hotchkiss drive has been continued. Another factor in the easy riding qualities is the improved upholstery which is now finished in plaited instead of tufted leather, besides being better sprung.

Power Development Increased 6 Hp.

More power has been given the car by making a series of small changes in the engine, while not altering its dimensions. Actually, an increase of 6 hp. has been obtained and the principal difference is in a re-arrangement of the valve timing and the use of an offset fulcrum on the valve rocker. This now gives a reduction of 2 to 1, whereas with the former arrangement a 1 to 1 rocker was employed. The practical result of this is that the cams give a longer dwell or open period of the valve, and this, taken in conjunction with the new timing, gives a higher volumetric efficiency and hence the gain in power. The engine output is now 41 brake horsepower at 2500 r.p.m. on the block. The only other change in the engine has been the employment of a Fabroil gear in the timing set. This is a compressed cloth gear of pronounced non-resonant qualities.

Axle Ratio Now 4.5 to 1

Structurally, the chassis is the same as it was a year ago, the only change in the running gear being in the wheels. There is a change in the drive, however, which is of a minor nature, and that is the substitution of another make of universal of the four-block type for that previously employed, and a change in the rear axle ratio, making it 4.5 to 1 in place of 4.25 to 1.

A number of improvements have been made in the equipment. The driver's comfort has been considered in the windshield, which is now an over-lapping type, so that the rain cannot blow through the juncture point of the two glasses. The top now carries a side curtain and pockets, and a little feature which may prove of great value in conserving the car is a connection of the dash lamp with the oiling regulation. By this arrangement the dash lamp acts as a pilot light and burns continuously while the motor is running so long as there is oil in the crankcase. As soon as the supply of oil ceases the lamp goes out.

Perhaps the most striking change in the car, since it is contrary to the trend of the past few years, is the placing of the spare tire carrier in the left front fender. This has been done for the sake of rigidity as it puts a solid supporting platform beneath the tire. It has been moved forward to such an extent that it does not interfere with the left entrance.

Engine Is 2 13/16 by 4¾

The power plant is an Oakland-Northway product of the overhead-valve, detachable cylinder head design. It has a bore of 2 13/16 and a stroke of 4¾ in. The six cylinders are

cast in a single block and the entire cylinder head carrying the valve action is removable as a unit. In fact, the engine is accessible to a high degree, as the overhead casting permits of reaching the valves and combustion chambers while the removal of the bottom pan allows the main bearings and connecting-rods to be inspected.

Cast-iron pistons are employed and these carry three rings, all above the wristpin. The valve mechanism is actuated from a single camshaft with the lifter rods on the exterior at the right side of the engine. These operate the valve rockers directly on a 1 to 2 ratio so that the lift of the cam is doubled. The rockers are assembled on two shafts, each carrying six of them with a support between each two and the rocker. The supports screw into the cylinder head and are easily removable when necessary. For adjusting the valves there is a nut at the top of the push rod at the point of contact with the rocker arm. The valves are 1¼ in. diameter in the clear and the lift is 5/16 in. The valve timing at present has the intake open at 17.5 deg. after upper dead center and close 38 deg. after bottom center, and the exhaust opens 42.5 deg. before lower center and closes 7½ deg. past upper center. This gives a 10 deg. lead of the exhaust over the intake opening for the creation of a vacuum in the combustion chamber. Formerly, there was a 5-deg. lead and this new timing in conjunction with the longer dwell of the valve opening has been an important factor in securing the 6 additional horsepower from the same engine.

Water Pump and Fan Combined

One of the features of the engine which is unique is in the front construction which combines the water pump impeller, fan and fan bearing. This makes a unit of the fan and water pump, with the fan belt driving both. The water connection is direct from this point to the radiator with the pump case a part of the cylinder block and also forming the fan support. Particular care has been taken to give an efficient belt with the simple adjustment, so that the layout can be readily taken care of by the average owner, and in fact requires little or no attention.

Both manifolds are separate from the cylinders and held to them by dogs and studs. With this arrangement in removing the cylinder head, the entire manifold connection can be taken off with it, and it is not even necessary to remove the carbureter when the cylinder head is taken off. In fact, about the most important connections to be attached are the water and exhaust manifolds from the radiator and muffler pipe, respectively.

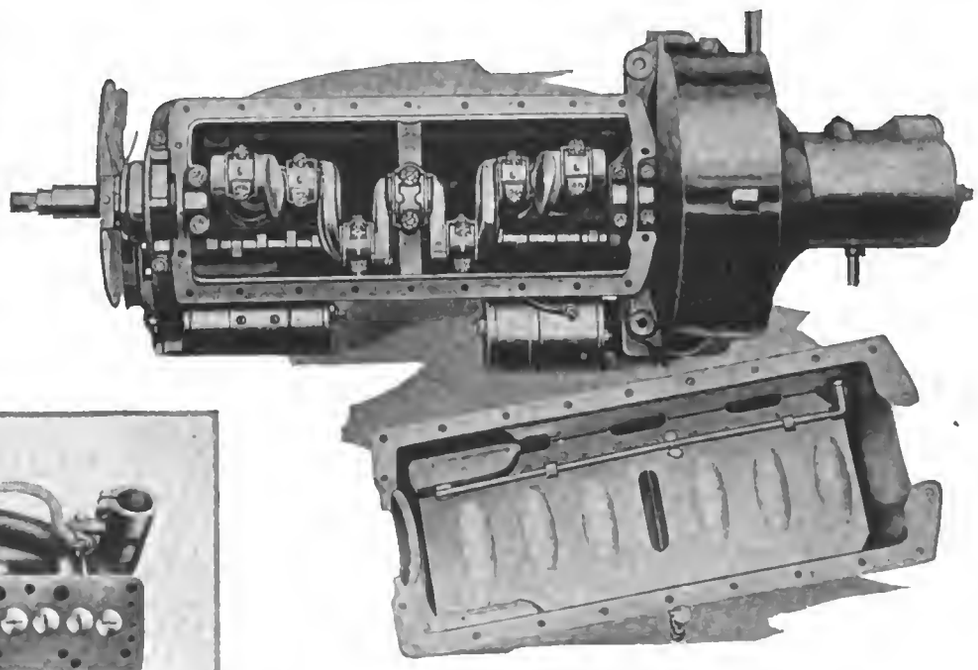
Gasoline feed is by the Stewart vacuum system in conjunction with a Marvel carbureter. The vacuum tank is on the front of the dash, that is, engine side, with the main tank having a capacity of 12½ gal. at the rear. The Marvel carbureter is provided with a heated-air intake and is mounted high on the engine, as shown in the illustrations.

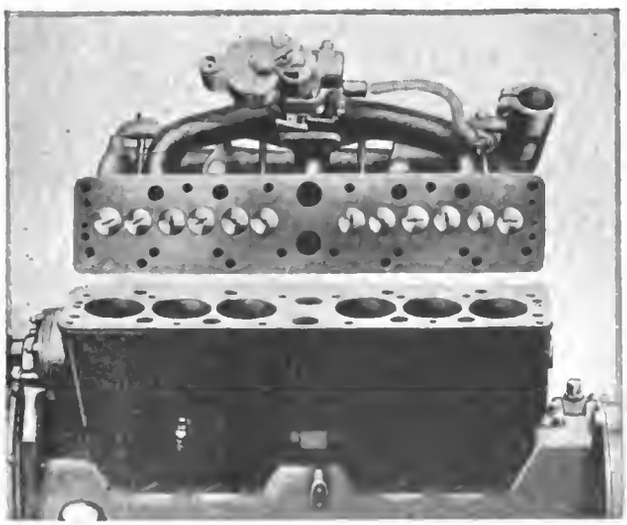
Delco equipment is used for ignition, lighting and starting. This was also true of the model 32 Oakland as far as the last 3 months of production are concerned. Before that time a different make was used.

Circulating Splash Oiling Continued

With the exception of the dash pilot lamp, no change has been made in the oiling system, a circulating splash system

Combined fan and water pump which is a feature of the new Oakland. The fan belt drives both units





The new Oakland engine, the view above showing the crankcase removed to give an idea of the accessibility of the connecting-rod and crankshaft bearings, and other parts which the car owner or repairman is frequently called upon to inspect. The view at the left shows the cylinder head removed, illustrating the easy access to the piston heads, valves and waterjackets

Engineering Details of Oakland 34

being used, operated by a plunger pump driven by an eccentric on the camshaft. This forces oil to a series of splash troughs and the three main bearings. A screen is provided through which all the oil must pass before it again reaches the pump, thus insuring a clean supply for circulation.

Unit Power Plant

Both the clutch and gearset are in a unit with the Northway engine. The clutch is a cone type with a ball bearing release and the gearset provides three speeds with reductions in the gearbox of 3.09 to 1 on low, 1.73 to 1 on second, and direct on high. The reverse ratio in the box is 3.98 to 1. These, of course, are multiplied by the 4.5 ratio in the rear axle for final reduction, giving ratios of 13.9, 7.8 and 4.5 on low, second and high speeds, respectively, and 17.9 on reverse gear.

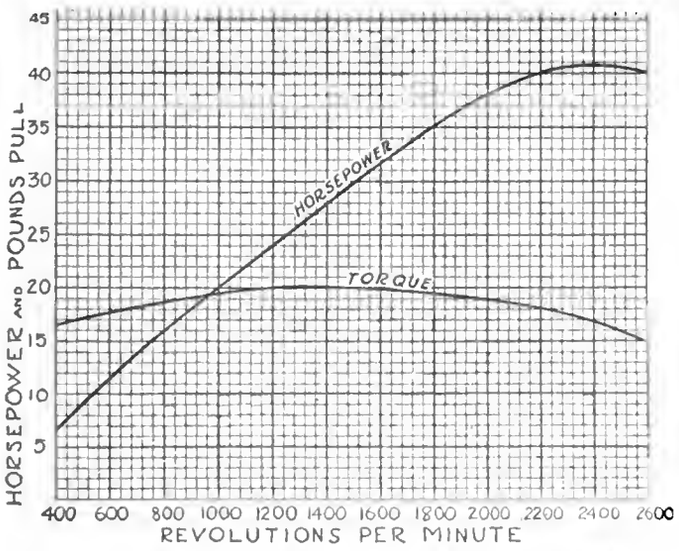
Frame Is Tapered

From the gearset the drive is taken through two universals and a hollow propeller shaft to the bevel gear rear axle. The master leaves and the front shackle bolts of the springs are the direct units in the Hotchkiss drive, transmitting drive and torque stresses, and hence have been made extra heavy in this construction. The elimination of torque tubes, arms, and radius rods, together with the simple brake layout, has given a very clean chassis, as is apparent from a study of the plan view. From this view it will also be seen that the rear springs are directed to meet the side members of the frame instead of outside and the entire frame has a pronounced taper to the transverse member at the rear of the engine. This gives a wide support which takes the body directly without the necessity for a sub-structure.

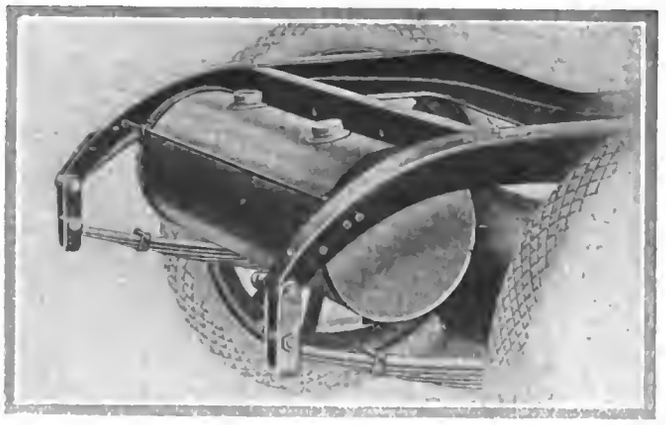
Floating Rear Axle

The rear axle is a Weston-Mott. It is a one-bearing floating type with longitudinally split housing. The brakes are external contracting for service and internal expanding on the hand lever. As will be seen in the plan view, the brake links are carried back to the rear transverse member, at which point they are broken with a short link to the rear. Adjustments are made by means of turnbuckles which are also illustrated in the sectional drawing of the axle which appears on the opposite page. The layout of the brake connections is also clearly illustrated.

The steering gear is a Jacox irreversible type with a 17-in. wheel. The control members are notably accessible with a ball type shifting gear within easy reach of the driver. The



Horsepower and torque curve of the new Oakland engine



Rear construction of the new Oakland, showing the mounting of the gasoline tank at the end of the frame members and the shackle for the semi-elliptic springs which replace the three-quarter elliptic type

floor is tilted beneath the cowl and the pedals project in such a way as to provide plenty of foot room for the driver, as well as the passenger in the front compartment.

Equipment Is Very Complete

In the way of fittings, the car is complete. The tires are non-skid in the rear, and all the necessary instruments including speedometer, ammeter, gasoline gage, switches, etc., are included at the list price. The top is a one-person design or it may be a close convertible at an extra price. The storage battery is an Exide having a capacity of 80 amp.-hr. at 10 amp. discharge rate. The speedometer is a Stewart and the car is provided with a full set of lamps, license plate bracket, electric horn and tools. Trimming is in genuine leather, with coach green for the body and wheels, with black for the fenders as standard. The prices are $845 for the five-passenger touring and two-passenger roadster, $980 for the closed convertible sedan model, and $970 for the closed convertible coupé. A year ago the car sold for $795 and the $50 difference in price is made up in the more expensive tires, bigger bodies, and generally better equipment of the new model.

Pre-Heating Fuel

IN the paper with which he opened the Detroit section season last month, C. F. Kettering mentioned the advantages of insuring that gasoline should not be too cold when it reaches the nozzle of the carbureter. It is also important that it should not be too hot. C. F. L. King has lately obtained a British patent for an exhaust by-pass intended to provide controllable pre-heating for gasoline or kerosene. In the cut the large pipe shown is the main exhaust line, and the annular chamber surrounding the branch, or alternative passage, is interposed in the fuel line between the tank and the carbureter. When the throttle shown is closed, as in the cut, all the exhaust gas passes through the branch and so heats the fuel in the annular jacket. When the throttle is opened the bulk of the exhaust will pass straight out, thus reducing the temperature in the branch.

In the abstract of the patent published in the official journal, no mention is made as to how the inventor proposes to link up the throttle. Presumably it could be interconnected with the main carbureter throttle with fairly good results.

Belgians Develop

SINCE the beginning of the European war some of the most interesting developments in armored automobile construction have been made by the Belgian army and the most recent constructions which they have produced are illustrated herewith. While no information as to the specifications and general details of these cars is yet available, it may be noted from the illustrations that the experiences of the war have borne fruit in their design.

For example, protection to the car, occupants and equipment has been made as complete as the ingenuity of the engineers who constructed it could make it. Even the rear wheels and rear axle are protected by armor plate as are the radiator and engine hood, in addition to the driver's compartment. Even the spare tires are carried so that they are protected from front and rear fire. Revolving gun turrets are fitted, equipped with either machine guns or rapid-fire light pieces, on the more heavily built types, while gun

New Armored Cars

shields which protect both the rifle and its operators, and which usually are made to revolve, are fitted to the cars designed for less formidable but speedier work, such as skirmishing, scout work, etc.

While the mechanical side of the new armored cars shows direct results of the sometimes costly experiences gained during the early days of the war, the exteriors reflect in another way the development in strategy which has characterized the entire struggle. They are painted in varying shades of gray, green, brown, etc., so that they will merge imperceptibly into the landscapes, whether they may be in wooded or open country, upon the meadows lands or the sand dunes by the sea. This color scheme is not only valuable as a protection against the artillery fire of the enemy, but also helps to prevent the whereabouts or movements of

Left—A good rear view of the Belgian armored cars, showing how the rear tires are protected from puncture by bullets. The cars are shown here advancing toward the firing line at a rapid pace

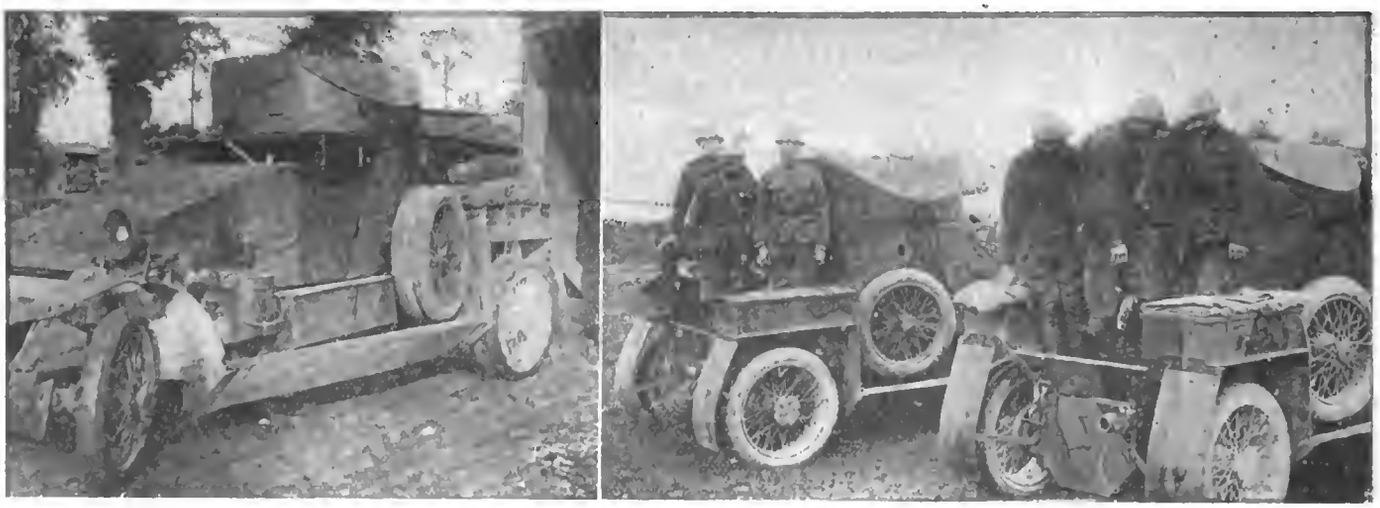
Two of the Belgian armored cars on skirmish work. Note the single large headlight and how the armor plate protects the engine hood and radiator. The motorcycle men are between the cars and the enemy so the crews are simply awaiting the word to advance

The Belgian armored cars in battle formation behind the lines. The cars differ in minor details such as the size and position of tool and ammunition box, etc. Note the steel-studded tires

the armored cars being discovered by hostile airmen, who are frequently hovering overhead searching with powerful field glasses for just such prey.

Touring Chassis Used First

The earliest Belgian armored cars, which won such renown in the first campaigns in northern France were built up from powerful touring car chassis fitted with machine guns and armor plating consisting of steel not less than 5 mm. thick, the gun being pivoted in the center of the single compartment. In some places a revolving pivot was fitted, while others merely had a shield in the front of the gun and revolving with it. The driver occupied the most central position in the machine and was practically immune from attack. He had a view straight ahead through a hinged shutter and in addition had a small port on the right, level with his head.



Left—A feature of the new Belgian armored cars is that there are practically no excrescences which may be shot away. Even the headlight is mounted close to the armor plated hood. Right—An excellent view of the rear construction used on the latest Belgian armored cars. Note the armor plate protecting the tires and the sheet across the rear

Extending Aluminum's Field

How to Make Best Use of Aluminum Alloy in Automobile Work While Avoiding Difficulties Outlined in Extracts from J. E. Diamond's S. A. E. Paper

THE fundamental advantage of aluminum is quite naturally that of lightness. The specific gravity of pure aluminum when cast is 2.59; when rolled, 2.68. The specific gravity of iron is about 7.21; that of steel somewhat higher. Thus, it will be seen, the weight of aluminum is for equal volumes but slightly more than one-third that of iron. The coefficient of expansion of aluminum is 0.000022 per degree Centigrade (Richards); that of iron is 0.0000119 per degree Centigrade (Roberts-Austin). The melting temperature of pure aluminum is 659 deg. C., or 1218 deg. F. The specific heat of aluminum is 0.22. Its thermal conductivity based on the conductivity of pure silver as unity is 0.313. Of the baser metals, copper, with 0.5, is the only one that exceeds it in thermal conductivity. The conductivity of iron is 0.11, or only one-third that of aluminum. It has recently been discovered that the thermal conductivity of aluminum increases with its temperature and at a temperature of 700 deg. F. is practically three times the conductivity at ordinary temperature. The electrical conductivity of aluminum is 60.5 per cent that of copper for equal volumes; and since copper is three times as heavy, its conductivity is higher, weight for weight. Aluminum is preceded by gold only in malleability, preceding in this respect silver, copper, tin and platinum. It ranks sixth in ductility. The tensile strength of approximately pure aluminum is about 15,000 lb. per square inch. Therefore, as far as strength is concerned, it is seen that even in the unalloyed state, weight for weight, it will compare favorably with fair grades of cast steel. It was early discovered that aluminum unalloyed was too soft and that structures cast in it lacked rigidity. A number of alloys have been developed and have corrected the inherent limitation of the pure metal, at the same time sacrificing only to a limited degree its fundamental advantage of lightness.

The most widely used alloying metals are copper and zinc. Copper and aluminum alloy particularly well with high or low content of either metal. The aluminum bronzes with high copper content have been found to be equal if not superior to any other bronze so far developed. The copper-aluminum alloy most commonly used has a tensile strength of about 20,000 lb. per square inch. Zinc alloys have been developed having greater strength, but at the present time probably 95 per cent of all automobile and aviation engine castings are made of copper-aluminum alloy.

Casting of Aluminum

The production of aluminum castings is a science in itself, and present-day success is built on many early failures.

Points on Casting Design

¶ Make the keynote the elimination as far as possible of complicated coring. When it is necessary, bend every effort so to design the job that as much of the coring as possible can be green sand work. Design as far as possible all sections with uniform thickness. In crankcase design do not try to decrease the thickness of the walls below 3/16 in. A thickness of 7/32 in. is better. The number of sound castings will increase appreciably if the foundry is granted this additional metal, and paradoxical as it may seem, the heavier casting can cost less because of the reduction in the defective casting loss. Design cases so that the ribs, brackets and bosses have plenty of taper. Further, have such parts join the main casting with liberal fillets. It is imperative that when a fairly light section runs into a heavy one that large fillets be employed. As far as possible, do not use loose pieces on the pattern for bosses. In most cases the green sand is not sufficiently strong and it is necessary to use dry sand cores, thus increasing the expense of the work.

It is a long cry from the first attempts of castings to the complicated work turned out to-day. The mere possession of the formulas of suitable alloys by the foundry is not all that is required. Haphazard methods in the foundry are not conducive to the production of sound castings. In the early days "hit or miss" methods in the metal room in the preparation of the "charge" resulted in a great variation in quality of castings.

It was found necessary in the furnace room to control the temperature, lest the metal be burned. Too high a temperature destroys the natural vitality of the metal, and castings made from this burned metal are brittle. In so far as strength is concerned, probably no one factor is of more vital importance than the pouring temperature. The lower this is the stronger the casting. The casting that has barely escaped being a "misrun" in the thinnest sections, because of a low pouring temperature, is the best casting from all standpoints. The reason for this is found in the rapidity of crystallization. Naturally, where the metal is poured cold, so to speak, the crystallization takes place quickly; and the crystals do not have time to arrange themselves in orderly manner, as they do if a longer time is granted. The production of successful castings requires careful attention to all the little details.

In the foundries of the Aluminum Castings Company technically trained men supervise every stage in the evolution of a casting, from the analysis of the virgin ingot to the delivery of the casting to the sand blast. Every foundry bay has a pyrometer, each casting being poured at the temperature an expert has determined to be the proper one; that is, just short of a mis-run. It is not too much to say that it is this technical oversight all along the line that makes it possible to produce so many crankcases in a day.

By far the larger number of aluminum engines are those in which the cylinders and crankcases are integral. This is an extremely rigid construction, and the aluminum makes a much lighter construction than the iron engines constructed after this design. Here again the overhead-valve engine is the favored type, although occasionally an L-head is found. Both the Marmon and the new Premier engines have overhead valves. Except in rare cases the heads of all these integrally-cast cylinder and crankcase engines are removable. From a structural and mechanical standpoint the ideal way to make this engine may be with the head integral, but it multiplies many times the difficulties in the foundry. In the present stage of the art it is doubtful if this type of construction can ever be placed on a production basis. The foundry occasionally finds itself taxed to turn out individual castings with integral heads. The cores in the heads are extremely intricate, and require the ingenuity of the best pattern makers and foundrymen to determine how to make and how to hold them properly.

Details of Sleeve Construction

The general practice has been to lay down a design similar to that dictated by past and current iron-cylinder practice, taking into account the modifications ne-

cessitated both by foundry and by mechanical requirements. The outside diameter of the cylinder barrels is made larger than would be the case with an iron engine, thus accommodating a cast-iron or steel sleeve. These sleeves are either a drive fit and forced into place with a light press, or steam or hot water is run through the jacket space and the sleeve dropped into place. It is essential to get the sleeve into place at once without loss of time, as otherwise it will heat and expand, sticking before it has been dropped home. This construction, in the main, differs from iron-cylinder construction only in that the piston and piston rings operate against an iron sleeve. In the overhead-valve construction this sleeve is flanged at the upper end, fitting in a corresponding recess. In the integral-head jobs, of course, it is necessary to put the sleeve in from the bottom.

When the cylinder blocks are not cast integrally with the crankcase, the bottom of the sleeve is machined flush with the bottom of the casting and is supported, although such support is not at all necessary, on the top of the crankcase, the cylinder opening being somewhat smaller than the outside diameter of the sleeve. When the cylinder head and crankcase are integral the sleeve can be flanged at the bottom and held by one or two machine screws. Another method is simply to upset the aluminum about the bottom of the sleeve.

A discussion of the use of aluminum in modern motor-car construction would not be complete unless mention were made of the Lynite piston. The aluminum piston has come and has come to stay. Any trouble existing has been in the nature of "growing pains." We have learned in the past year that it is not wise to attempt to carry weight-saving to the limit. In other words, we should all be fully satisfied in cutting the weight of an iron piston in half instead of following the exact design of the latter in order to avail ourselves of the two-thirds saving in weight. The metal thus added will have beneficial effects if employed in increasing the length and the wall thickness of the piston. I have always advocated a long piston with a reasonably thick skirt. In a paper given before the Detroit section of the society last winter I advocated a length equal to one and one-third the piston diameter. The long piston with a fairly heavy skirt will take care of piston slap and should help materially in preventing oil pumping. On account of limitations that cannot be removed, occasionally it may not be found advisable to substitute aluminum pistons for iron ones in an engine already built. The piston unquestionably is the heart of the engine, which should largely be built around the piston.

The use of the aluminum brake-shoe is another step in the direction of unsprung weight reduction. Aluminum brake-shoes lined with suitable brake material have rendered eminently satisfactory service when and wherever tried. Aluminum brake-shoes have not had much vogue in America, but in Europe both the Panhard-Levassor and the Peugeot companies use Cothias permanent-mold aluminum brake-shoes on all their models, both touring cars and trucks. Ordinarily brake-shoes of conventional design lend themselves extremely well to production by the Cothias process. We have produced Lynite permanent-mold brake-shoes, in some cases imbedding in the casting a steel slug to take the action of the expansion cam. Unquestionably future development in car construction will be in the direction of refinement of details, and I am certain that the aluminum brake-shoe will be heard from in the next 3 or 4 years.

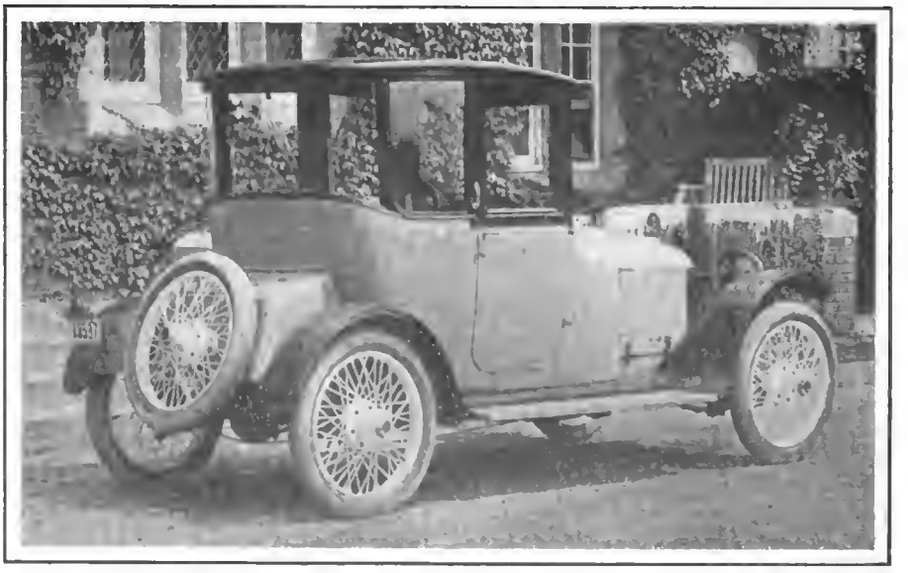
Machining Qualities

Casting for casting, aluminum can be machined nearly twice as fast as cast iron, resulting in a corresponding reduction in cost. Fewer men, consequently smaller floor space, are demanded when the shop is laid out to machine aluminum than would be the case with cast iron. Considering the ease with which an aluminum casting can be handled in the machine shop, from the unloading platform to the assembly floor, to say nothing of the rapidity with which the casting can be put through one machine after another, comparative costs will show aluminum, even with the abnormal conditions prevailing, with an increased initial cost for castings as a consequence, to be quite competitive with cast iron. When the market is normal, considering initial costs, casting for casting, it will be found that it is cheaper to use aluminum than iron.

Some time ago a certain manufacturer whose crankcases were machined outside his own plant considered the use of an iron crankcase in the belief that he might reduce his costs. It happened that the manufacturer was, and will be for some time to come, dependent on one shop for the machining of his cylinders and crankcase castings. The manager of this outside shop refused point-blank even to consider machining iron cases, stating that the trouble they were having with the one iron casting was quite sufficient.

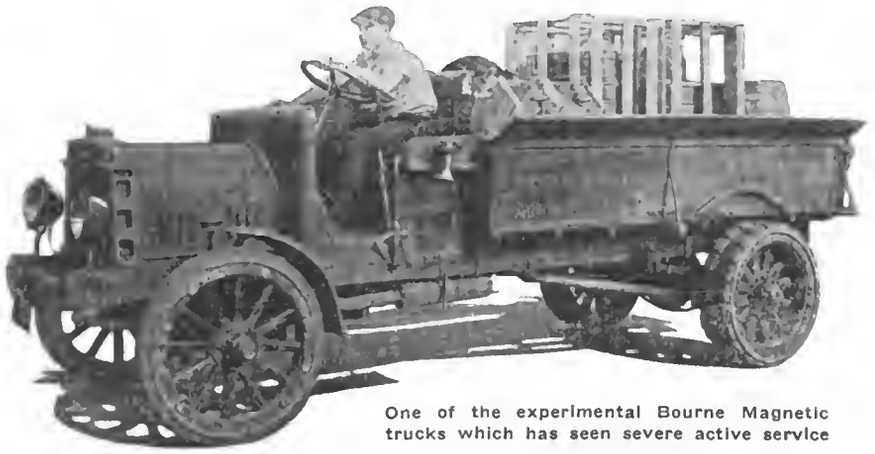
Coupé Body for Scripps-Booth Four Chassis

THE coupé body illustrated herewith has been brought out by the Scripps-Booth Corp., Detroit, Mich., for mounting on its standard four-cylinder chassis. The characteristic mounting of the spare wire wheel at the rear of the tool and luggage compartment has been continued, the only part of the body differing from the well-known roadster being the coupé section from the dash to the rear deck. The body is luxuriously finished and maximum light is assured by the almost continuous glass sides, curtains being provided for use if desired. This model is particularly designed for use by doctors and business men who desire an economical closed car for use in cold weather. The price of the coupé model mounted on the standard four-cylinder Scripps-Booth chassis, as illustrated herewith, is $1,450.



Bourne Truck Has Magnetic Transmission

New Vehicle Employs Same Unit as Owen-Magnetic Car



One of the experimental Bourne Magnetic trucks which has seen severe active service

THE Bourne Magnetic Truck Co., Philadelphia, Pa., will soon be ready to deliver 2-ton and 3½-ton trucks with a magnetic transmission precisely similar in its method of operation to the Owen transmission used on Owen-Magnetic passenger cars. Experimental vehicles have been driven thousands of miles in actual service, the one illustrated on this page having been used by the Atlantic Refining Co., of Philadelphia, and another has been doing express work in New York City. A great reduction in wear and tear on the chassis and substantial economy in operating costs are claimed to have been proved for the transmission by these tests.

The chassis built is not an entirely new creation erected around the electric transmission unit. S. N. Bourne has built a number of special trucks with gear transmission of which a majority are in the service of the Atlantic Refining Co. They have a number of points of interest quite apart from the transmission, the most noticeable being a special method for mounting the springs. These, as shown in the illustration, have no shackles in the ordinary sense of the word. Instead the end of the spring is flat and makes a square contact with a rocking block, this having a rounded head which rests in a groove provided for it in a bracket attached to the frame.

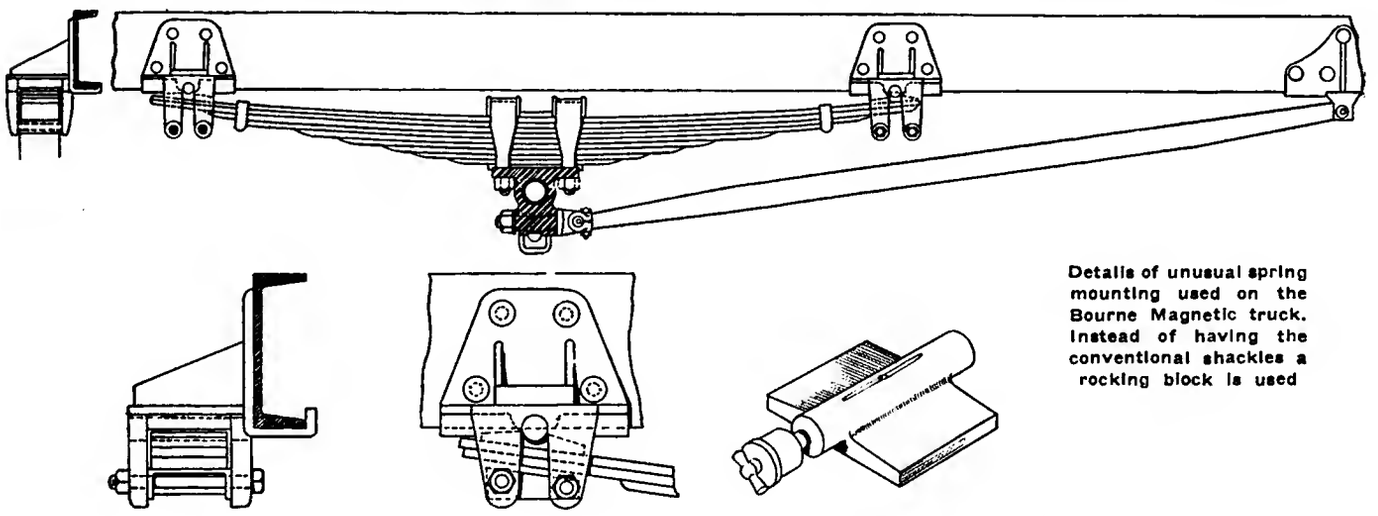
The best of material is used throughout the truck and it is to be observed that the driver's seat, dashboard, fenders and similar parts have an exceptional rigidity and strength. In developing trucks to suit the very strenuous service required by the Atlantic Refining Co. in the distribution of petroleum products the ability of different parts to shake loose was soon demonstrated and that the detail fittings as now supplied are solid enough to withstand any amount of jarring.

Naturally, these trucks are not in the cheap class, the 2-ton chassis costing $3,150 and the 3½-ton $3,850. The engines used are similar, both having 5½ in. stroke and a five-bearing crankshaft. The bore of the smaller engine is 4 in. and that of the larger 4¼ in. The cylinders have individual removable heads giving maximum facility for cleaning out the combustion chambers. A non-adjustable type of carbureter is fitted and ignition is provided by high-tension magneto with fixed spark. An electric lighting and unusually powerful starting system is, of course, provided by the transmission.

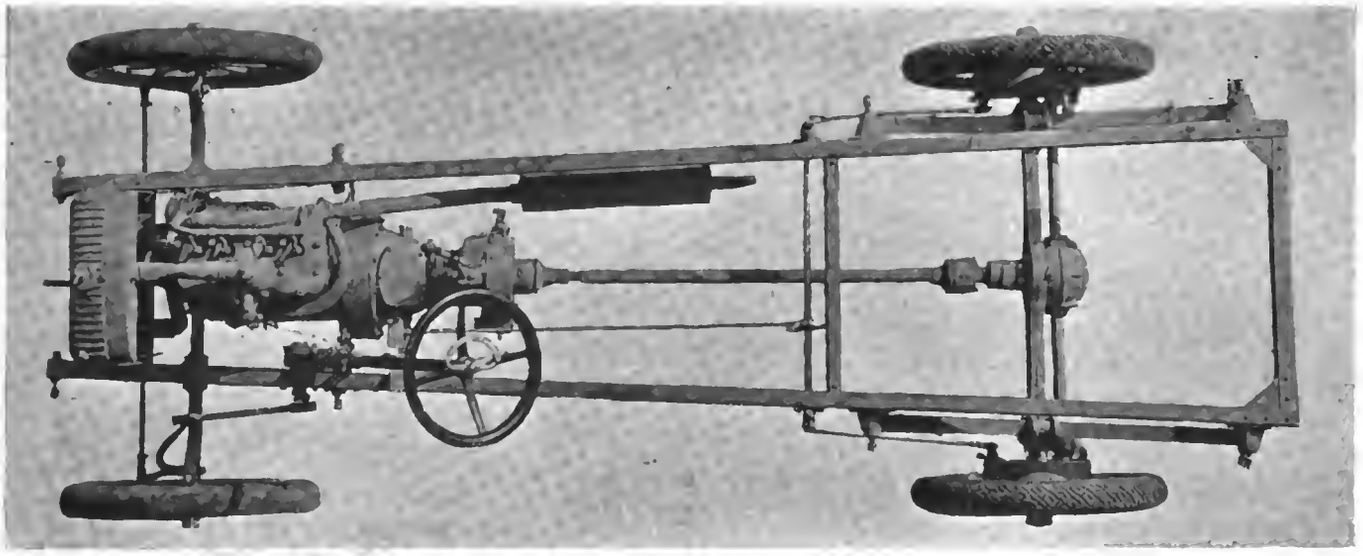
The transmission is mounted integrally with the engine, being bolted up to the crankcase precisely as on the Owen-Magnetic car. The control operates exactly like a throttle lever, the engine control being confined to a foot accelerator. Both trucks are governed, the smaller to 15 and the larger to 12 m.p.h.

The frames are constructed to give a maximum flexibility, the side rails being 6-in. chrome vanadium channels and the cross members little more than distance pieces to keep the side rails apart. This means that a very large amount of weave is permissible and cannot result in loosened rivets. The power plant is mounted on three points so arranged that any distortion of the frame cannot possibly transfer stress to the crankcase.

The rear axles are of the worm type and carry two sets of inclosed brakes. In addition to these, which are operated by the usual pedal and hand lever, there is a powerful electric brake which can be brought into action any time when the truck is moving. This brake consists of an arrangement of switches which causes the part of the transmission driven by the rear axle to operate against a strong electrical resistance and the electric brake is applied by the movement of the same lever which controls the different electrical speeds.



Details of unusual spring mounting used on the Bourne Magnetic truck. Instead of having the conventional shackles a rocking block is used



Chassis of new 1500-lb. Republic truck, showing clean design, power plant mounting and tapered frame

Originality in 1500-Lb. Republic

FEW firms in the motor truck industry have grown as rapidly as the Republic Motor Truck Co. of Alma, Mich. This concern is planning to make 23,000 machines next year and more than half of these will be the new 1500-lb. delivery truck which will be known as the Dispatch model. The first of these is now on its way from the factory to Los Angeles, on a demonstration run.

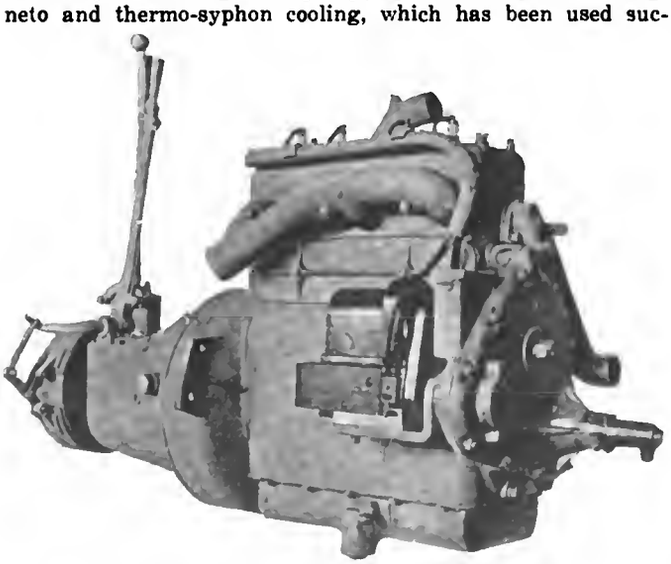
The chassis is in every respect a truck engineer's job and is therefore capable of being run on solid tires. Pneumatic tires can be used and either of the following tire equipments will be provided, 32 by 4 in. (non-skid rear) pneumatics, or 32 by 3 front and 32 by 3½ rear solids.

The engine is new, having been designed especially for this particular chassis. It has a bore and stroke of 3½ by 5 in. with cylinder barrels cast integral with the crankcase. The crankshaft is quite unusual, as it has ball bearings; the diameter is 2⅛ in. and there is no center bearing, the rigidity being obtained by making the cheeks of a massive section. There is a detachable head which greatly facilitates removal of carbon, and the valves are arranged in a normal L-head manner being 1⅝ in. diameter. The lubrication is maintained by a submerged oil pump; ignition is by Bosch magneto and thermo-syphon cooling, which has been used successfully by the Republic company on other models, is also adopted for this, the smallest of the range.

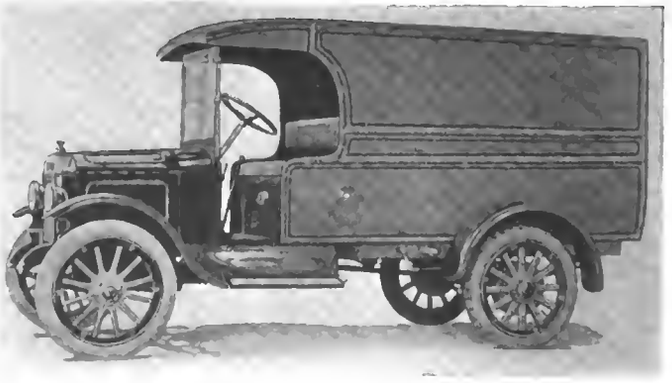
The transmission, which gives three speeds, is bolted up in unit with the engine, the flywheel being inclosed in a bell housing. It contains a multiple dry disk clutch. The internal gear axle is a Torbenson.

As typical of the robust nature of the chassis, the frame layout shown in the illustration should be noticed, and another typical truck feature is the radiator which has cast tanks and a special form of core. There is one standard wheelbase of 110 in., but two bodies are provided. One of these is the regular express type with canopy top and side curtains and it is this model which sells for $750. A large solid panel type is provided for an extra $25. The length of either body is 81 in. and the width 42½ in., the height from floor to top being 54½ in. As to the color scheme, the Republic yellow wheels are adhered to, the body being finished in Brewster green. A glass windshield and electric lights are included in the equipment, the necessary current being provided by a Bosch generator. Starter is extra.

Somewhat similar in general design are the Republic models 10 and 11 rated at 1 ton and 1½ ton. These have wheelbases of 124 and 144 in., the model 10 costing $1,095 with either express or stake body and the model 11, $1,275 for the chassis only. The engines of models 10 and 11, like model 9, have a 5 in. stroke, but the bore differs being 3½ in. for the model 10 and 3¾ for the model 11. The 2- and 3-ton chassis will not be materially changed.



New 3½ by 5-in. power plant used in Republic Dispatch truck



Republic Dispatch truck of 1500 lb. capacity, with panel body

Ramps a Feature of Hudson Garage

Will Cut Overhead $18,250 Per Year Besides Saving Each Customer 20 Min. Per Day—Four-Story Structure Will House 600 Cars in Individual Spaces

A FOUR-STORY garage to store 600 cars without the use of an elevator is in course of construction by the Hudson Motor Car Co. of New York. It is estimated that it will cost $600,000. By the use of two 20-ft. ramps in place of elevators the company has not only saved each customer nearly 20 min. time each day, but it has saved itself a heavy overhead expense of about $18,250 per year. This is based on engineering facts giving the cost of each trip of an elevator as 10 cents. Approximately 250 cars would be going up and down these elevators each day, thus giving the above figure. In regard to the time saved by the use of ramps, it is stated that there is no possible chance of congestion and it is possible for a car to come down the ramp from the fourth floor to the street in between 10 and 15 sec. The space taken by the ramps is equal to that taken by the elevators.

The new garage being built by the Hudson Motor Car Co. of New York

The garage will be public and is being built on a plot of 41,000 sq. ft., giving at least 4 acres of storage space. It will run 100 ft. west of West End Avenue to the New York Central tracks and clear through from Sixty-eighth to Sixty-ninth Streets.

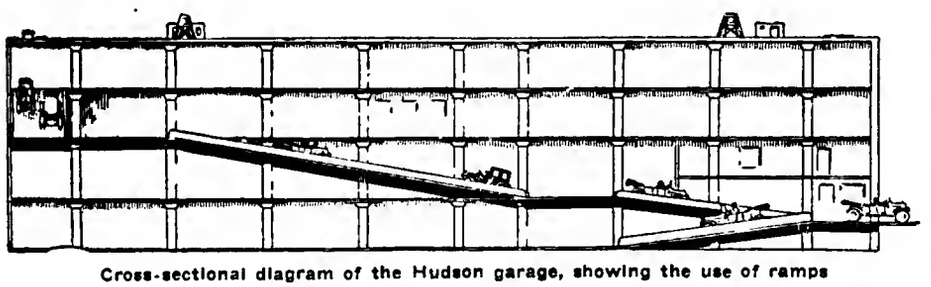
Every point in construction and equipment has been well looked after. The ramps, instead of running in spiral form as in the garage of the Automobile Club of America, reach their respective floors in practically a straight line, there being only one turn from the third to fourth floors. The ramps will run at an angle of from 10 to 15 deg. One will go to the first floor and the other will go to the other floors. The use of these ramps eliminates the inevitable delays of elevator service. Each set of ramps is divided by a concrete curbing, thus eliminating all danger of sideswiping when cars are going in opposite directions. Two cars can pass comfortably on the ramps, thus avoiding any possible congestion on the up or down trip. Extra precaution has been taken against skidding on the ramps by the use of an abrasive metal. During the busy parts of the day, there will be an attendant on each floor entrance to guide the cars from their floors, thus eliminating all danger of possible collision.

A scientific layout has been adopted in the car spacing. Each customer is assigned a specific space and number. Each space is provided with a concrete guide 10 ft. long, 49 in. wide and 4½ in. high, located under the car between the wheels. The car can thus only enter the space when it is lined up correctly. A small bumper, 6 in. high, is provided for blocking the rear wheels. There is a 14-in. space between the running boards of the cars. Each car is pushed out into the 18-ft. aisle to be washed right in front of its space. The company has introduced, due to its architect, H. B. Mulliken, portable washing racks for each of the twenty aisles. These racks or cranes are run on an overhead track and are equipped with a cape large enough to cover a car so as to protect the other cars from splashing. A row of electric lights inside the cape is also equipped. Hot and cold water and compressed air are conveniently placed in each aisle. As the rack is moved to one end of the aisle, it is quickly and conveniently connected with either the hot or cold water by means of an air-brake coupling, another feature introduced to save time.

Each car space is provided with a spacious locker, large enough for two tires and other equipment.

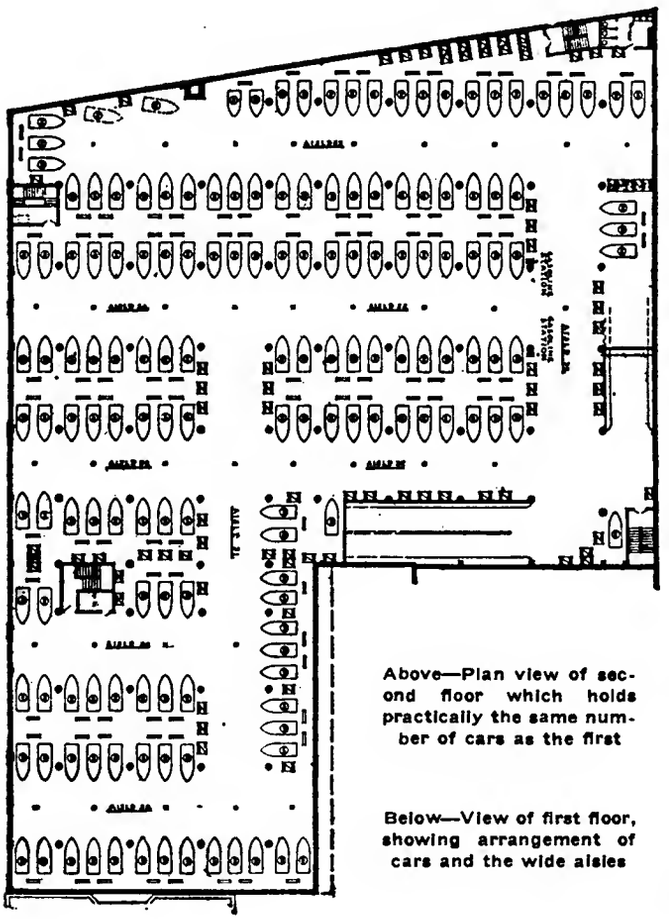
Part of the fourth floor will be used as a club room for the drivers. There will be a barber shop, library, restaurant, billiard and pool room and a smoking room. Each will be completely furnished by the company which will control each department. Meals will be furnished at cost.

Much has been planned for the convenience of customers. For instance, each floor will be equipped with a signal, which will flash the number of a car wanted. This device will be controlled at the office on the ground floor. Time is also saved by the installation of telephones on each floor. There will be a large supply



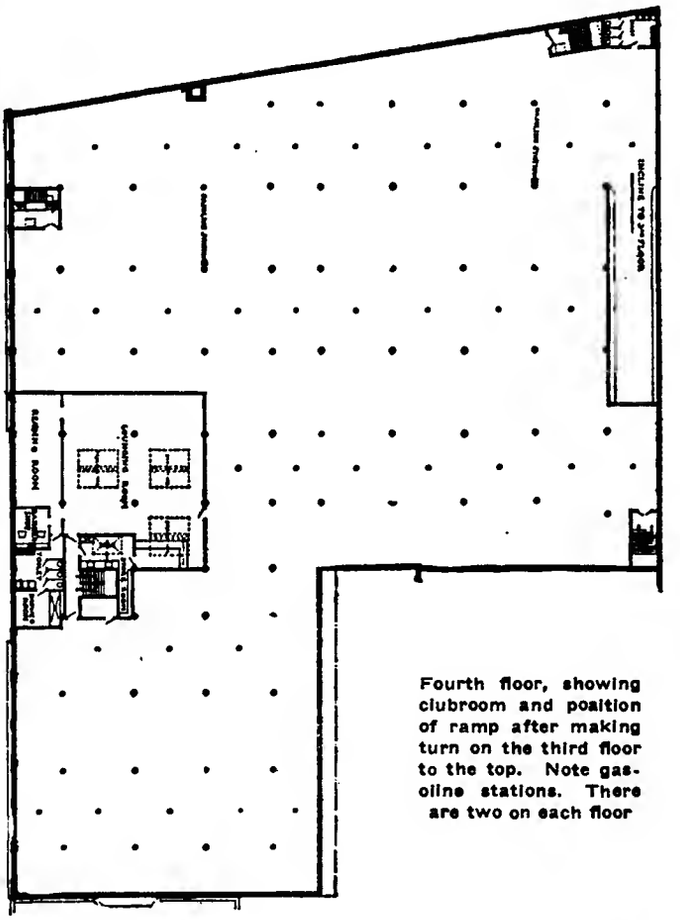
Cross-sectional diagram of the Hudson garage, showing the use of ramps

Layout of the Four Floors in New Hudson Garage

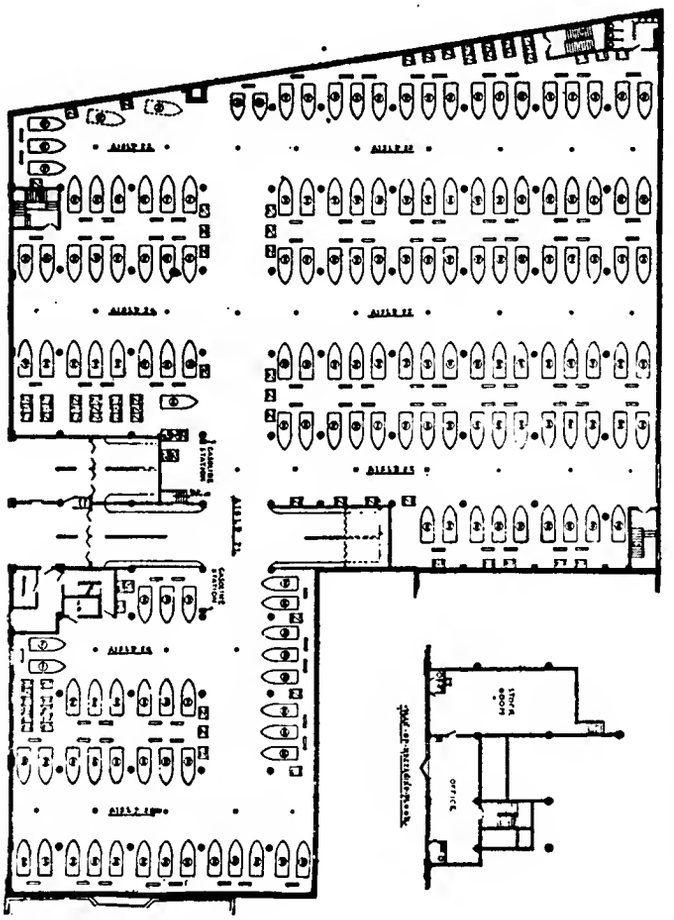


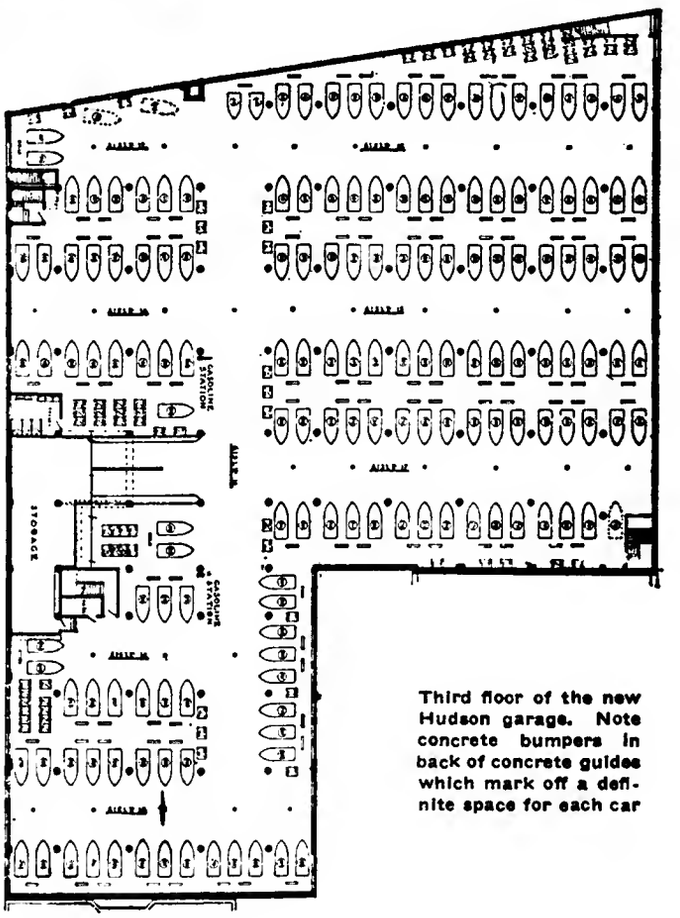
Above—Plan view of second floor which holds practically the same number of cars as the first

Below—View of first floor, showing arrangement of cars and the wide aisles



Fourth floor, showing clubroom and position of ramp after making turn on the third floor to the top. Note gasoline stations. There are two on each floor





Third floor of the new Hudson garage. Note concrete bumpers in back of concrete guides which mark off a definite space for each car

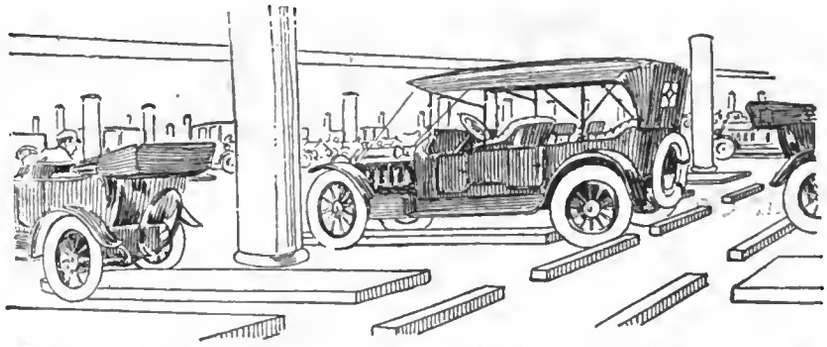
department on the ground floor. The Allen pressure system will be used for pumping gasoline and oil to each floor. A gasoline storage capacity of 23,000 gal. will be available. There will be a machine shop on the fourth floor, 40 by 100 ft., where chauffeurs will be allowed to work on their cars free of charge.

Only Two Entrances

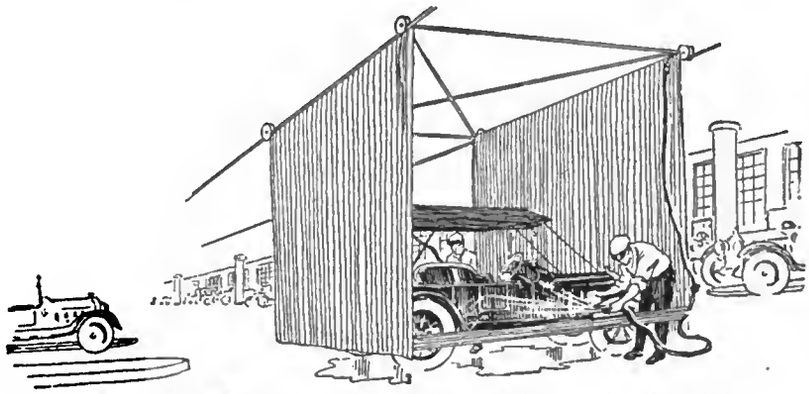
There will be two entrances only, these being on Sixty-eighth Street. Exits in case of fire will be established, two on Sixty-ninth Street and two on the West End Avenue side of the building. For fire protection an automatic sprinkler system will be installed. There will also be sand pails and Pyrene fire extinguishers placed at short distances apart on the floor. In addition to these precautions, automatic steel shutters will be installed to cut off each floor in case of fire. These shutters are held open by fusible connections which will melt when a fire occurs allowing them to close. A large siren horn will be installed on the floors and will be used in case of fire.

Details Well Planned

Such details as checking all outgoing and incoming cars, keeping track of each person that enters the building, provision for adequate lighting, etc., have been given careful attention, always with the practical side of the application of each in view.



Each car has its own space in the Hudson garage and is blocked by concrete bumpers so that an aisle is kept open between the cars



A feature of the garage is the use of portable washing racks, there being one rack to each aisle

The FORUM

Air Cooling and Two Cycles to Solve Troubles

By Charles E. Duryea
Consulting Engineer

THE AUTOMOBILE for Oct. 12 contains two articles that should be read together understandingly, and that this may be done I venture to call attention to them. Mr. Manning shows us that present day gasolines contain liquids having boiling temperatures of 175 to 210 deg., and Mr. Kline tells very properly of lubrication troubles traced to kerosene from the fuel diluting the oil in the crankcase and thinning it so it failed to lubricate.

Having recently been the victim of ruined bearings undoubtedly due to some such cause I feel strongly on this subject. One engine was run for many months with a rather small radiator, and aside from getting rather hot, gave no lubrication troubles. Duplicates of this engine were fitted with larger radiators and kept cool. "Impossible to make them boil" and similar remarks were heard concerning them. But bearing troubles followed. Not once, but more than once on the same job, and after great care had been taken to know that the oiling pump was working properly and that the oil line to the bearings was clean and open.

Cooling Too Efficient

It may seem like a far cry to blame the large and efficient radiator for the burned out bearings, but experience forced me to believe that there was a connection and that our fuel was being cooled too much after entering the cylinders. The temperatures mentioned by Mr. Manning show conclusively that my belief was correct.

Very few water-cooled engines run with their walls above 175 deg. unless controlled by thermostat. While on short, hard pulls they commonly exceed this temperature, they may run for miles at a time with much of their wall surface considerably below this temperature. Every particle of liquid that has a higher boiling point and strikes such a cool wall will remain liquid and work down to the lubricating oil unless the heat of the combustion for an instant may raise the temperature beyond the boiling point and partly vaporize it. Anyone who has noticed that a paper tag pasted on the bottom of a kettle or frying pan will remain there during many a dinner cooking can readily understand how unlikely it is that any instantaneous application of heat will vaporize such fuel so long as the wall is below the boiling temperature.

Many suppose that compression heats the new charge and vaporizes it. This is true if the liquid continues to float in the mixture, but any drops that are on the walls, or any vapor in contact with the cool walls, remains cool in spite of the compression and, since the temperature does not raise the compression, opposes vaporization, and tends to increase the liquid deposit on the walls.

Suggested Remedies

These are the conditions. What is the remedy? The first easy, proper one is to use hotter engines. Keep the walls so hot that no liquid fuel can remain on them. A thermostat that holds the water temperature well to the boiling point will catch the lower boiling point fuels, but it will not serve for the ones that have boiling points as high as 210. Who knows but that there may be even higher boiling points in use? A second remedy is to pass all the fuel through the crankcase as in two-cycle practice. This may sound foolish, but let the man who thinks so tell us the objections.

The maker who knows that kerosene will enter his crankcase in definite quantities can provide for lubrication accordingly. It is the engine which is not designed for such a mixture that suffers. It is the uncertain and indefinite mixture of kerosene with the oil that upsets the oiling system.

By mixing a high fire test oil with the fuel and feeding the mixture through the carbureter into the crankcase, we do away with mechanical means for lubricating the engine and its crankcase parts. We substitute fresh oil for the ever more diluted mixture that causes the trouble. We get a known and satisfactory oiling mixture instead of beginning with oil and ending with mostly kerosene and an unknown proportion of the original, but now old and dirty oil. Surely this is an advantage. This remedy assumes that the engine is so constructed as to pass along any oil more than the proper level, as most engines do. Anyone who has over filled his crankcase and seen excess smoke in consequence understands this. Any kerosene splashed on the piston head inside will be vaporized and pass along with the mixture as it is drawn from the case to the cylinders. The oil is less likely to vaporize and so tends to remain.

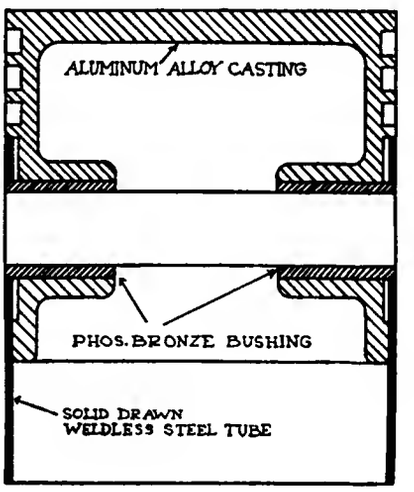
Air-Cooled Two-Cycle Engines

To step further in the answer to this problem I suggest air cooling, so that the cylinder walls may without question be hotter than the fuel boiling point, and two-cycles, which, if air cooled, have crankcases quite warm and tend to properly vaporize the mixture while in the crankcase. Both these things are in the line of simplicity and economy and will come as soon as the public learns enough about the automobile to decide for itself instead of buying what Jones buys or Smith sells.

Aluminum-Steel Piston

By W. H. Bishop

WITH reference to the recent article in THE AUTOMOBILE by A. Ludlow Clayden, on Aluminum Pistons, I beg to inclose print and outline specification of my composite aluminum and steel piston and trust same will be of interest to you, as it appears to entirely provide the type of piston which your article calls for to overcome the drawbacks and disadvantages of the present type aluminum piston.



With my design you will note the following points:

1—Simplicity.

2—Small cost of manufacture over and above the ordinary type piston.

3—Saving in weight of aluminum.

4—The amount of aluminum exposed to cylinder wall is only approximately one-

tenth of the total length of the piston; the outer wall of piston consisting practically of the steel liner and piston rings.

The piston consists primarily of two parts—a cast aluminum alloy head with extension which extends to just below the wrist-pin bosses. Fitting around the aluminum casting is a steel tube, the lower extremity of which extends well below the skirt of the casting and the upper portion is carried up to the first piston ring. The steel tube has two holes to take the extreme ends of the wrist pin, and the steel tube is located and held in position by the pin.

It will be noticed that the amount of aluminum alloy exposed to the cylinder wall is only approximately one-tenth of the total length of the piston, the outer wall of the piston consisting practically of the steel liner and piston rings, thus insuring, with the combination of the steel liner and the rings, a perfect gas-tight piston.

With regard to weight of this piston compared with ordinary cast-iron pistons, a good saving in weight is effected. For example, a typical cast-iron piston of 4-in. bore weighs approximately 4 lb. as against an approximate weight of 2 lb. with an aluminum alloy piston with steel liner. As regards cost of production, these pistons can be produced on an economical basis as a minimum amount of aluminum alloy is required owing to the short length of piston skirt, by making the liner from solid drawn weldless steel tube cut to length and machined to required limits.

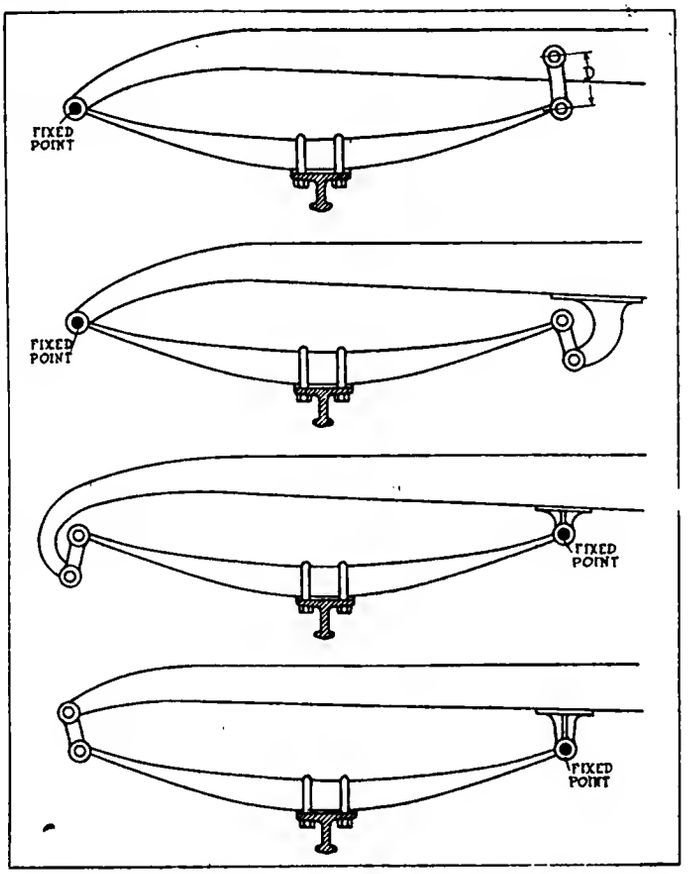
Spring Attachment as Shackle-Bolt Rattle Eliminators

By G. E. Wendle
Williamsport Electric Co.

I HAVE been much interested in your recent articles on spring designs as applied to pleasure cars, and in order to extend the field, I am taking the liberty of requesting you to open wide the columns of your magazine to persons with spring attachment experience.

As an automobile enthusiast, I find one of the greatest annoyances in and about cars to be the rattles and noises, due, in many cases, to shackle bolts. Various manufacturers have made modifications in application of the shackle links, push or pull, various changes in the center-to-center distance of shackle bolts and in using oil lubrication instead of grease. All these changes have been tried over and over again by the makers, and still the rattles and noises continue.

Would this not be a subject of wide interest to automobilists? The trouble is common to all and if your columns were opened to reports of improved methods, etc., would it not likely result in placing the matter of spring attachment on a better engineering basis.



Forms of spring attachments to frame and front axle, showing usual designs of shackling. The length of shackle links D varies widely in different designs, once the angularity of shackle links varies similarly

Wants Other Views

The sketches on this page show the front axle layout. Of course, the rear axle comes with the question.

The method of lubrication and shackle bolt design both vary widely. What are the advantages and disadvantages of the various methods of attachment, lengths of shackle links, grease or oil lubrication, etc.—as shown by operating experience with pleasure cars? What kind of bushing—bronze, graphite-filled bronze, impregnated wood, or other material has proved most satisfactory?

If this article attracts the attention of some of our engineers I shall greatly appreciate reading their views.

Owen-Magnetic in Coupé Form

THE Owen-Magnetic coupé, claimed to be especially suited to women drivers, is now on exhibition in the company's salesroom at Broadway and Fifty-seventh Street, New York City.

The new car was especially designed for women drivers, and more particularly for those who are afraid to drive in the congested thoroughfares. The new coupé is designed for three passengers but an extra seat for a fourth person is provided which folds out of sight when not in use.

The car has a wheelbase of 125 in. and there is ample room under the rear deck.

New Owen-Magnetic coupé especially suitable for the use of women drivers

The Rostrum

Reader's Idea for Sporting Phaeton

INDIVIDUAL and exclusive design has at last come into its own. The automobile enthusiast of to-day is not compelled to pay a very high price for a car modeled after his own design. The chassis can be purchased from any manufacturer and in the case of the lower-priced cars selling around $1,000 or more, an additional expenditure of $1,000 for a body and its accessories will give the owner a car suited to his own ideas and uses, and above all a car which he knows is his own individual creation. In large cities hundreds of these special jobs may be seen, every one having an air of luxury and style about them that compels immediate attention. The higher priced the chassis, the more luxurious the body and since a few thousand dollars is a good price to pay for a car nowadays the purchaser of a car of this price is entitled to an expression of his own ideas, if he has any.

Predicts Long Wheelbases

The writer has endeavored to show by the accompanying illustration the possibilities of uncommon design in the open types. The reader will at first glance call it a freak. With a little more study he will find that it is original, luxurious and a sport car, without any sport disadvantages. The design here shown embodies one idea that has never been expressed on a stock model nor on very few special jobs. There are other points of design that are uncommon, and will be explained in order. The writer predicts cars of very long wheelbases as the road conditions of the country improve. The wheelbase of the car shown in the illustration is approximately 155 in. The reason for this being the position of the radiator, the roomy body both in the driver's compartment and the tonneau, and the position of the rear seat which is slightly forward of the rear axle. However, it will be noticed that by placing the radiator over the front axle and shortening the space in the cowl and reducing the space between the rear wheels and the doors that the wheelbase will be considerably reduced. The chassis is hung very low yet with the usual road clearance. Long flat springs are used, the rear ones being almost horizontal with the frame and are of the heavy underslung cantilever type. The writer is convinced that springs of this type will offset any disadvantages as to the riding qualities of the car by placing the rear seat in front of the axle. The frame and rear springs are so built as to keep the chassis at all times horizontal with the road. There is nothing more unsightly than the back part of a motor car several inches higher than the front part, a feature which gives the car the appearance of running down hill all the time.

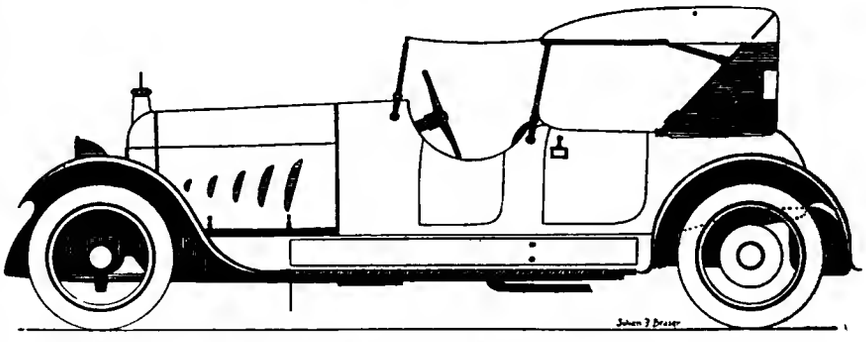
Radiator the Starting Point

The radiator is of the large, rounded type with a large water cap, and mounted several inches back of the front axle. This is the starting point, in designing the rest of the car. In order to get fast, racy lines, the body must have the appearance of flowing away from the radiator, bonnet and cowl. The bonnet and cowl rise gradually in a straight line to the slanted windshield. Note that the steering column, which is pitched quite low, is mounted close to the cowl within easy reach of its instruments. Note the curve of the cowl. This gives a sporty appearance to the body as well as facilitating the driver in the handling of the car. Note the double cowl and its windshield, a feature found on very few cars. It is collapsible, folding backward out of sight into the back of the front seat, a light wooden roll curtain raised from the floor and locked on to the top of the cowl hides it completely from sight as well as offering protection from breakage. Note the large door in the tonneau, its size in proportion to the fore door, and that the sides of the tonneau are quite high yet not topheavy. The upholstering is of the heavy armchair kind, barely showing above the top of the body, the thick cushions resting flat on the floor of the body. Note the bulbous back and the manner in which it is pitched forward, giving the body the fast, sporty lines of a phaeton. Note the shape of the top, which covers only the after part of the car. Its design is superior to the Victoria type since it permits a better view when raised. In order to protect the occupants of the front seat in rainy weather a curtain pulls out from the top and is fastened to the front windshield. It is also rigid enough to support side curtains if they are desired. Note that the fore doors are much smaller than the rear ones and that the handles are left exposed to break the smooth sides. There are no moldings around the doors, they fit flush with the sides of the body. Note the shape of the louvres in the hood.

Six-Cylinder Engine

The engine is of the six-cylinder type with worm drive having its own starting and lighting system as well as tire pump. Wire wheels with 35 by 4-in. tires are used. The gas and oil are carried in a tank in the rear, the tools and batteries between the frame, and running boards. The spare tires can be carried in the rear against the bulbous back or on the running boards and fenders. Note the shape of the one-piece oval fenders; they as well as the hood and body are made of aluminum, the best material for automobile body work. The radiator and other metal trimmings are of brass, highly polished. The color is preferably a light one.

The body and hood embody the streamline idea from bumper to tail light and the writer is convinced from what he



Suggested design for a sporting phaeton evolved by Julian F. Brasor, Chicago, Ill.

has actually seen in body construction that this design could be executed by any good body builder. It must be remembered that the secret of handsome design is entirely in the chassis. If the chassis has not been designed with the appearance of the body in mind, the whole will be a hopeless failure and a waste of time, money and energy.

Chicago, Ill. JULIAN F. BRASOR.

Best Temperature 170 to 180 Deg.

Editor THE AUTOMOBILE:—I have a 30-hp. Chalmers car. Kindly advise me as to what temperature the water in the radiator must be kept in order to get the best results from the engine, and how the temperature of the water may be found.

2—Which is the best water to use, soft or hard water, or is there no difference?

Rockford, Ill. L. C. W.

—The best temperature of the water is probably about 170 to 180 deg. If you fit a Boyce Moto-Meter on the radiator cap this will show you when the temperature is right without the necessity for reading it in degrees.

2—Soft water is much to be preferred to hard because it does not make any deposit in the radiator or cylinder jackets.

Information on Horsepower Taxes

Editor THE AUTOMOBILE:—Kindly give facts concerning the horsepower tax on automobiles.

Has anything been done to bring about the adoption of some horsepower rating based upon piston displacement? Such a method of rating, it seems to me, would be somewhat reasonable, but the idea of rating a 3¾ by 4 in. engine the same as a 3¾ by 6¾ engine is absolutely absurd.

If all engines ran at the same piston speed, which is not the case and never will be, then the old formula $\frac{B^2}{2.5} \times N = \text{Hp.}$ would mean something. According to this formula the two sizes of engines mentioned would each rate at 22½ hp. for four cylinders. One has a piston displacement of 177 cu. in. and the other 298 cu. in. With equally good design these two engines could not possibly develop the same power, so why give them the same horsepower rating and why tax them the same?

I think this subject should be of considerable interest to the readers of THE AUTOMOBILE and I hope that someone on your staff will give us some information on it.

Detroit, Mich. R. E. C.

—You will find the subject of rating and horsepower formulas discussed in an article on pages 700 to 704 in this issue. Rating by the standard formula is, of course, absurd but there are some objections to rating by piston displacement and the $\frac{D^2N}{2.5}$ formula was really quite good when it was first taken into use.

The horsepower tax on automobiles varies in different States. Practically all the States using this basis of taxation make their ratings by the formula $\frac{D^2N}{2.5}$ but the amount of the license fee or tax is determined in different ways. In some States the scheme used is to have a fixed fee for cars up to certain horsepowers. For example: In New York it is $5 for cars up to 25 hp., $10 for cars from 25 to 35 hp., etc. In other States there is a fixed fee for horsepower. It is 50 cents in California. The other States, as a rule, have a set tax without regard to horsepower.

Raw Linseed Oil as Tar Remover

Editor THE AUTOMOBILE:—Your answer to the inquiry of A. E. J., Westmount, Que., Canada, in THE AUTOMOBILE for Oct. 5, regarding removing tar from a car body prompts me to state that I believe you will find that raw linseed oil will serve the purpose best wherever tar or road oils have been splattered upon the body of the automobile or other finished surface. It is a fact that linseed oil will readily dissolve tar and this residue can be easily washed from the surface of the body without harming the latter, by the use of soap and water.

Philadelphia, Pa. H. A. M.

All-Weather Bodies for Allen

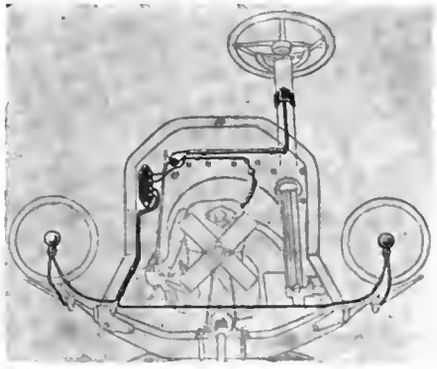
Inside view of Allen coupé. Note roomineas for passengers in front seat. The driver's seat is located slightly in advance of the other, so that there will be ample space for manipulation of the control levers. The price is $1,075

Allen roadster and touring car with all-weather bodies. These bodies are convertible, the sedan being of the type in which the roof is permanent and the windows and door fillers can be removed to a compartment, back of the rear seat. Price, $1,095

ACCESSORIES

Constolite for Fords

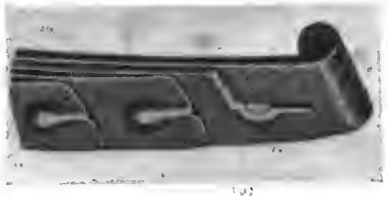
THIS device is a combination of coils which automatically regulates the light from the headlamps, increases the brilliancy of the light at low speeds and provides for dimming. It also will keep one headlight burning if the other bulb is broken. The device is wired from the magneto and is controlled by a switch on the steering column. The coils are stated by the manufacturer to be so perfectly balanced that the operation of the magneto is not affected in any way. The unit is attached to the right side of the dash under the hood beside the terminal end of the lighting switch. When the headlights are in multiple a light of two to five times as much power as with the standard arrangement is claimed, and at 20 m.p.h. or more the light is constant. No additional wiring is necessary and connections can be made from the instructions furnished with each equipment. The device is waterproof and no adjustment is needed. It sells for $4.85.—Detroit Starter Co., Detroit, Mich.



Laycut of Constolite headlight regulator

Stanley Self-Lubricating Spring

The main features of these springs are oil pockets provided in the ends of every leaf so that the springs may be lubricated with an ordinary oilcan. The pockets are fitted with felt pads which retain the oil, so that it is only necessary to supply lubricant two or three times a year. The action of the spring sufficiently distributes the oil throughout the surfaces. Price, Ford, $4.50 up; Hudson, $5 up; Cadillac, $9.50 up; Packard, $9.50 up; other makes in proportion. —Fulton Sales Co., 910 Michigan Avenue, Chicago.



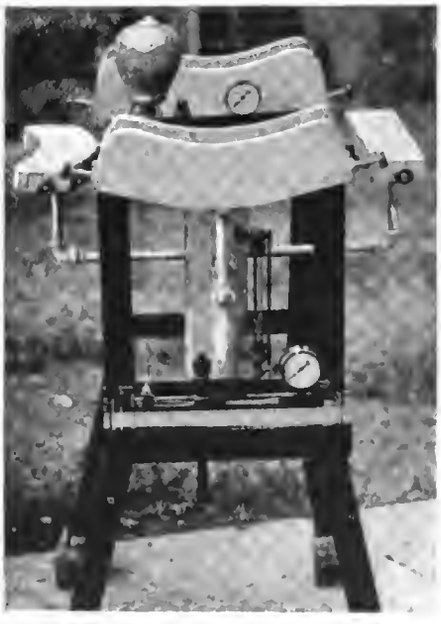
Stanley self-lubricating spring

Tracford Tractor Attachment

With this device any Ford may be converted into a tractor in 2 hr. It consists of a rectangular sub-frame which bolts onto the rear of the Ford frame, and which carries two heavy steel wheels driven by roller tooth gears on the axle ends, meshing with internal gears on the wheels.

The ratio is 9 to 1, which gives a total reduction of 32.6 to 1. The machine is designed to operate on high gear exclusively, and since the reduction is 9 to 1, the speed of the motor at 2 m.p.h. is equivalent to that of a Ford car running 18 m.p.h. The drawbar pull is, normally, about 1200 lb., and if low gear is used, but only in an emergency, the pull may be anywhere up to 2000 lb. The cooling efficiency is increased by adding a pump.

In attaching the Tracford it is necessary to drill only two holes, one in each side member of the frame. The machine is designed for all sorts of farm work, including drawing spring-tooth harrows, rollers, mowing machines, binders, corn harvesters, potato diggers, and plows. Price, $125.—Standard Detroit Tractor Co., 1506 Fort Street, West, Detroit, Mich.



Anderson steam vulcanizer

Anderson Steam Vulcanizer

This gasoline-operated steam vulcanizer for repairing tubes and casings is equipped with a large sectional mold which will take care of a 16-in. section in 4-in., 4½-in. and 5-in. tires, and a small sectional mold for sections to 15 in. in 3-in., 3½-in. and 4-in. tires. The tube plate has a capacity of four tubes, and seven tubes can be treated at one time when the section molds are not in use. The normal capacity is three casings and four tubes. Price, $125, including set of tools.—Anderson Steam Vulcanizer Co., Worthington, Ind.

Premo Transmission Flanges

A flange for the Ford transmission designed to facilitate the removal and replacement of the cover. It is fitted to the crankcase under the transmission and is tapped to receive the retaining bolts, which are screwed into it instead of into nuts. The retaining bolts are put in from the top and may be tightened up making an even pressure the whole length of the gasket. The advantage of the flange is that it is not required to hold the nuts from below. Price, 75 cents per set.—New York Motor Car Devices Co., Eleventh Avenue, New York City.

Kennedy Signal

In this accessory, two signals, one on each of the rear fenders, electrically controlled from the driver's seat, indicate either by night or day the intentions of the driver. Each signal is controlled independently and turns in the direction you intend to go, showing two red lights, an arrow and the word "Turn," and remains a signal until the turn is completed. A pilot light, attached to the switch, shows that the signal is in working order. Price, $12, complete with wiring and

Tracford for converting Ford car into a tractor

Premo transmission cover flange for Fords

Kennedy automobile signal

Goodrich switch lock. By its use the switch is locked when the motor is shut off

switches.—Nu-Way Tire and Rubber Co., 1004 South Michigan Avenue, Chicago, Ill.

Goodrich Lock Switch

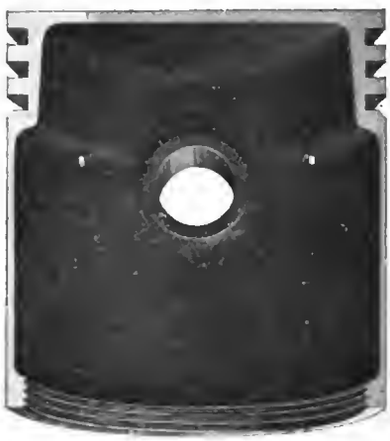
A switch for Ford cars operated by a Yale lock. The device takes the place of the regular ignition switch, and may be attached in little time, as its screws fit the screw holes already in the coil box. The switch cannot be removed when locked, as metal shutters cover the screw heads. Throwing off the current to stop the motor locks the switch, thus removing the possibility of forgetting to lock it. Two keys come with each switch. Price, $3.25.—Goodrich Accessory Assn., 809 Widener Bldg., Philadelphia, Pa.

Mecco Creeper

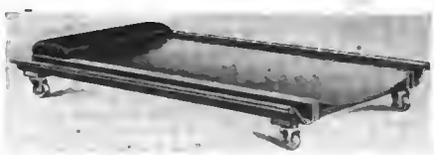
The Mecco creeper is 20 in. wide, 36 in. long, with a smooth steel curved body and padded head rest. There are pockets at the sides for holding tools and small parts. Weight, 15 lb. Price, $2.—Moeschl-Edwards Corr. Co., Inc., Covington, Ky.

Thiefoil Ignition Lock

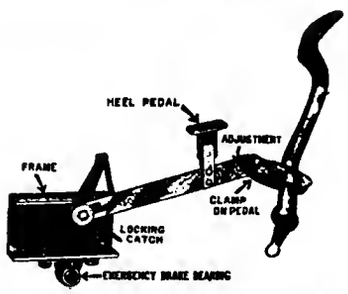
A combination ignition lock that is applied to the face of the standard Ford switch without making any changes in the wiring arrangement. Three buttons project from the top of the lock and each must be pressed the correct number of times to complete the circuit. Pressure on one of the buttons throws the switch off. Each of the buttons operates a notched disk that must be rotated until the notches come in line. A trip-pin



Semi-steel piston. Note the thin walls and drilled holes for the return of excess oil to the crankcase



Mecco creeper for use under car



N. Y. clutch control for Fords

then falls into the groove and the lock mechanism is released. More than 1000 working combinations are possible and the entire installation may be made by the purchaser. Price, $3.50, complete with hose and connection.—Caskey-Durpee Mfg. Co., Marietta, Ohio.

N. Y. Clutch Control

This device permits the clutch of the Ford to be locked in the neutral position. A pedal operated member connects the clutch pedal to a hanger bolted to the frame just above the emergency brake bearing. A spring holds the locking catch from acting until pressure is placed on the locking pedal, the device having no effect on the operation of the clutch pedal in changing from low to high. The installation requires no machine work and may be done by the owner. Price, $3.—New York Coil Co., 338 Pearl Street, New York City.

Semi-Steel Pistons

These light semi-steel pistons are made for any car. They are cast from metal patterns and because of the thin wall are extremely light, though strong. The weight of the piston for Buick cars is 1 lb., 11 oz. Cylinders are rebored by this company, fitted with new pistons, rings, wristpins and bushings; shipment made in 24 hr. after receipt of cylinders. Price, $2.80 each, for Buicks, all other cars in proportion.—Allen & Curtiss Co., 415 S. Main Street, Mishawaka, Ind.

Truckford Attachment

Converts a Ford into a 1-ton truck, leaving the chassis intact. The Ford rear axle becomes the jackshaft and carries the sprockets for the chain drive, the attachment bolting on over the frame. The lengthened frame gives a loading space of 8½ to 11½ ft. back of the driver's seat, making the wheelbase 128 in. Solid rubber tires are used on the rear and carry almost the entire load. The Truckford may be attached by two men in a short time, and may as readily be removed and the original body replaced. Price, $350.—Robinson Machine Co., Detroit, Mich.

Truckford attachment for converting Ford car into a 1-ton truck

Kerosene Is Choice of Independent Oil Men

(*Continued from page* 683)

Dr. Lucke discussed this subject very fully in a lengthy paper on kerosene devices which he read at the June meeting of the Society of Automobile Engineers this year. On that occasion he stated very positively that the problem of successfully burning kerosene in an ordinary automobile engine had been solved.

Starts on Kerosene

The Good vaporizer uses a heating device which consists of a very long venturi contained within the exhaust header. This venturi is made as long as the design of the header permits, and mixture is fed to this venturi by an ordinary carbureter. This naturally delivers a very wet and unsatisfactory sort of gas, but this is changed to a warm dry mixture at the far end of the vaporizing tube, whence it is taken directly to the intake header. In the section shown in Fig. 1, it will be noticed that the intake manifold is arranged directly beneath the exhaust, so that the gas does not have to pass around the cylinders in order to get to the intake valves. Dr. Lucke states that this assembly permits precisely the same delicacy of throttle control and as good idling as can be had with gasoline. An essential feature is the placing of the throttle between the spray nozzle of the carbureter and the vaporizing venturi. The effect of the throttle is to disturb the nature of the gas and of the heated venturi to remove the effects of such disturbance. One of the main virtues of the Good instrument is the great length of the venturi, because this permits a very high velocity in the front, while it does not cause the great drop of pressure and therefore limit the possibility of cylinder filling.

The most interesting feature of the Good system is that it permits an engine to be started up exactly as though it were operating on gasoline. Passing through the intake manifold from end to end is a small tube of thin steel. At the end of this is a burner fed with kerosene sprayed by a small electric blower and ignited by a series of sparks which can be provided either by a magneto or by a battery fitting. Dr. Lucke says that this vaporizing tube will attain a red heat in 15 sec. and when in this condition it will vaporize any mixture reaching the intake manifold to a sufficient extent to enable the engine to be started and to permit it to fire regularly until the main venturi heats up.

The burner operates so quickly that the whole engine and the burner can be started simultaneously. If the engine is cranked with the ordinary self-starter and the blower is in operation simultaneously, the time taken to start is, according to Dr. Lucke, the same as that required for starting with heavy gasoline in cold weather. It is best, however, to arrange to control the blower independently so that it can be started by pressing a button a few seconds before the main engine is cranked. By this means the deposition of kerosene in the intake manifold or in the cylinders is prevented. Dr. Lucke says that with this device there is no smoke and little carbon accumulation and that the operator would never know that he was using kerosene except that in cold weather he would have *less* starting trouble than he now experiences with gasoline.

September Gasoline Exports Increase 83 per Cent

WASHINGTON, D. C., Oct. 23—Exports of gasoline during September totalled 37,857,477 gal., an increase of 17,230,058, or 83 per cent, as compared with 20,627,419 gal. shipped abroad in September, 1915. Exports of gasoline for the 9 months ending September were 274,816,625 gal., an increase of 67,757,366 gal. over the corresponding period of 1915.

Lubricating oil totalling 23,690,556 gal. was exported in September, an increase of 5,197,105 gal. over September, 1915. Shipments for the 9-months' period were 204,513,350 gal., a gain over the same period in 1915 of 21,737,145 gal.

Illuminating oil exports were 89,189,368 gal. in September as against 68,381,361 gal. in September, 1915, and for the 9 months ending September 637,830,762 gal., compared with 643,964,310 in the same period of 1915.

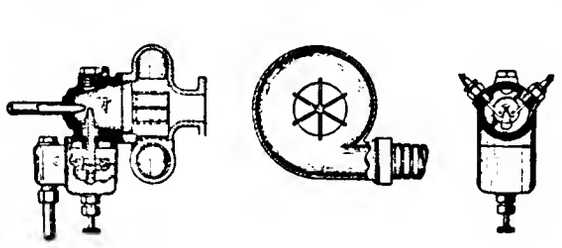
Packard-Missouri Managed by Loomis

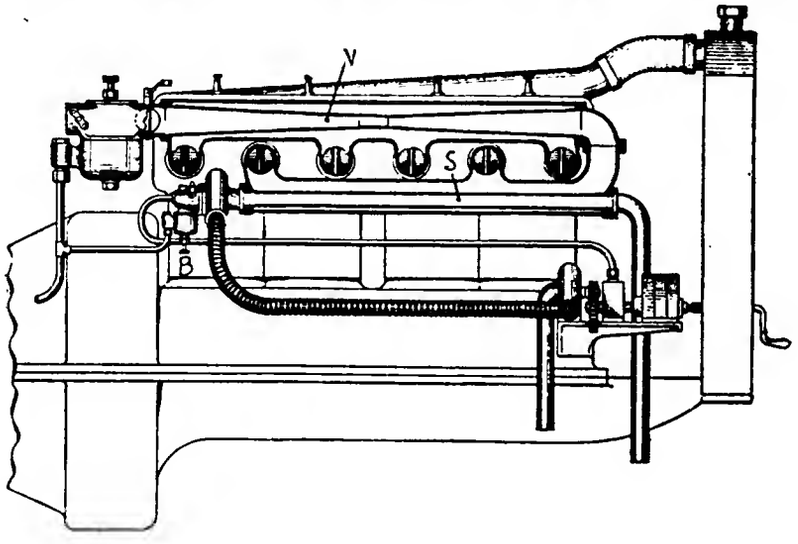
DETROIT, MICH., Oct. 23—G. S. Loomis, formerly in charge of the Packard interests at Louisville, Ky., is now the general manager of the Packard-Missouri Motor Co., St. Louis. H. W. Spaulding who formerly held this position has been made vice-president in charge of sales.

—

Ward Leonard Patent Licensees

BRONXVILLE, N. Y., Oct. 25—One of the largest patent licensing transactions was concluded to-day when the estate of the late H. Ward Leonard, originator of the Ward Leonard Electric Co. of this place, granted a non-exclusive license under all of Ward Leonard's electrical patents to the General Electric, Westinghouse, and Cutler-Hammer companies. The consideration is perhaps the largest that has ever been paid in a patent license arrangement. In all, upward of seventy-five Ward Leonard patents are concerned in the deal. A feature of the deal is that all three companies agree to recognize the work of Ward Leonard by having the system in their product known as the Ward Leonard system. The field covers such electrical controls as used for mine hoists, turret training, rheostats, circuit breakers, rolling mills. and everything excepting controls for automobile lighting and gearboxes.





Arrangement of the Good kerosene vaporizing system, showing the long venturi V in the exhaust header. Starting is accomplished on kerosene by means of the electrical lights burner B, which heats the tube S in the inlet manifold. The detail sketches show the construction of the burner

Industrial Miscellany

Factory

Goodyear Tire & Rubber Co., Akron, Ohio, has posted notices in its plant informing all workmen that beginning Nov. 1 the regular 8-hr. workday schedule will be effective. For nearly 2 years the firm has been gradually working toward that goal. Some of the departments have been on an 8-hr. schedule for some time.

Good-Wear Rubber Co., maker of tires and other rubber goods, will operate a plant in Elyria, Ohio, at the Topliff & Ely plant. Within 4 months, the company expects to be turning out from 160 to 200 tires per day. About 100 men will be employed at the start. Jacob Murbach of the Elyria Milling Co. will be vice-president and W. E. Brooks, president of the Elyria Telephone Co., will be treasurer of the company.

Western Malleables Co., Beaver Dam, Wis., maker of automobile castings, is improving its works. The Elm Street plant is being enlarged by a brick and steel addition, 26 by 90 ft., and a new and larger core room and sand shed. An air compressor room is being erected at the South Street plant.

Aluminum Castings Co., Cleveland, Ohio, has started work on a large plant development to be devoted to the Lynite pistons. The company has purchased 18½ acres at East Forty-ninth Street and the Newburg & South Shore Railroad. The price was about $75,000. The first factory building to be build is to cost $125,000. It is to be 900 ft. long. The company expects to occupy it by December. Other buildings will be erected as needed.

Canadian National Carbon Co. will build a factory at Toronto, Ont.

Ontario Steel Products, Ltd., Brockville, Ont., is making extensive additions to its plants at Brockville, Ont., and Chatham, Ont. The company recently signed up contracts with three automobile companies for springs which will cover production for nearly 3 years.

Perfection Motor & Tire Co., Madison, Wis., will erect a plant in Niagara Falls, Ont., to cost $35,000.

Maple Leaf Tires, Ltd., Belleville, Ont., has secured a factory site there of 22 acres and building operations will be commenced at once. The main building will be nearly 300 ft. long and will be of concrete and steel construction, and will cost approximately $100,000.

Maxwell Motor Car Co. will commence work at Windsor, Ont., shortly on the erection of a plant to cost $60,000. A site was purchased some time ago.

Personals

E. M. Taber, truck sales manager for Russell P. Taber, Hartford, Conn., has been promoted to be manager of the wholesale department which covers Reo passenger and commercial vehicles. Under his new assignment he will have entire charge of the wholesaling of Reos in the territory covered by Taber, nearly all of the State. W. E. Walker succeeds E. M. Taber as manager of the truck department.

W. H. Wetherell, head of the Saxon department of Frank G. Robins, Inc., Hartford, Conn., and formerly a member of the firm of Kingsbury & Wetherell, has joined the Saxon factory forces as a district representative.

F. A. Wright, St. Louis, has been appointed sales manager for the Weber Motor Car Co., Studebaker distributor, that city.

C. Snyder has become general works manager of the Parker Rust Proof Co. of America, Detroit, manufacturer of rustproof liquid for motor vehicles. He was formerly superintendent of manufacture for the Chalmers Motor Co.

W. Leahy, of Albany, N. Y., has disposed of his holdings in the Kingsbury-Leahy Co., designer and builder of automobile bodies, to devote his attention to other business interests.

J. L. Wierengo has been appointed general manager of the Detroit Truck Co., Detroit, maker of the Tonford truck. Mr. Wierengo was formerly the advertising manager and sales manager for the Continental Motors Co.

W. E. Kenyon has resigned as general sales manager of the Sandow Motor Truck Co., Chicago, his resignation to take effect Nov. 15. His future connections will be announced later.

S. E. Straight will be in charge as branch manager of the Savage Tire Corp. factory branch in Detroit.

H. K. Reinoehl has resigned from the Sayers & Scovill Co., Cincinnati, maker of motor-driven funeral cars. He has joined the A. Howard Co., Galion, Ohio, as chief engineer.

J. E. Dockendorff & Co., 20 Broad Street, New York City, has been appointed general export agent by the Central Steel Co., Massillon, Ohio.

Mason Motor Car Co., New York City, has taken on the Monroe car in connection with the Ross Eight.

Adams-Bagnall Electric Co.'s New York office is now located in the Engineering Building, 114 Liberty Street, under the management of F. C. Perkins, Eastern representative.

H. W. Johns-Manville Co. has opened a branch office at Great Falls, Mont., on the fourth floor of the Ford Building, in charge of J. H. Roe. With the opening of the Great Falls office the Johns-Manville Co. increases its number of branches to fifty-five.

March 6-10 — Boston, Mass., Show, Mechanics' Bldg., Boston Automobile Dealers' Assn.
March 6-10—Ft. Dodge, Iowa, Northern Iowa Show, New Terminal Warehouse, G. W. Tremain, Secretary.
March 14-17 — Davenport, Ia., Show, Coliseum Bldg., Tri-City Automobile Trade Assn.

L. B. Miller, St. Louis, has resigned as manager of the St. Louis branch of the U. S. Tire Co., to become general sales manager for the Inland Machine works, makers of the Inland piston rings. Mr. Miller had been with the U. S. Tire Co., since March 1, 1913 and manager in St. Louis since Dec. 1, 1915.

A. E. Schaefer has been appointed business manager of the Scripps-Booth Corp., Detroit. Mr. Schaefer was the business manager for the Sterling Motor Co., prior to its merger with Scripps-Booth.

Fred W. Chaffee has been made the manager for the George W. Franklin Co., Detroit. Mr. Chaffee was connected with the Dort.

H. S. Farish has been appointed assistant to the president and general manager and also purchasing agent of the Abbott Corp., Cleveland.

E. Guenther has been appointed manager of the accessory store of the Puritan Machine Co., Detroit. Mr. Guenther was formerly accessory salesman.

W. P. Kennard has been employed by the King Motor Car Co., Detroit, as a travelling sales representative—his territory at the present time is in the middle west.

M. C. Bias has been appointed purchasing agent of the Mitchell Motors Co., Racine, Wis., to fill the vacancy caused by the resignation of Guy W. Morgan, who has become president and general manager of the Abbott Corp., Cleveland, Ohio. Mr. Bias served as assistant purchasing agent under Mr. Morgan.

Henry Fink, Milwaukee, has been appointed sales manager of the Columbus branch office of the Sterling Motor Truck Co., Milwaukee, Wis.

A. G. Waddell has been appointed special representative of the Chevrolet Motor Co., on the Pacific Coast, with headquarters at the new Chevrolet factory at Oakland, Cal. He will have charge of the advertising of the states of California, Oregon, Washington, Idaho, Utah, Nevada, Arizona, New Mexico and the Islands of the Pacific.

Alvan T. Fuller of Boston, Mass., has extended his Packard agencies to New Bedford, where he has placed F. C. Graves in charge of a new branch just opened there.

J. T. Clinton has been sent from New York to Boston to take charge of the New England branch of the Firestone Tire & Rubber Co., succeeding T. J. Glenn, who has secured a long leave of absence due to illness.

J. B. Dub has been transferred from Atlanta, Ga., where he managed the Studebaker branch. to the branch at Worcester, Mass. The latter company has just leased new salesrooms and service station on Main Street.

J. R. Corby, St. Louis, has been appointed manager of factory branch in that city of Chicago Pneumatic Tool Co., makers of Little Giant truck.

Earl Freese, Indianapolis, Ind., has been appointed manager of the Logansport, Ind., branch of the Gibson Co., Overland distributors and accessory dealers. He will succeed E. C. Kurman who has been made manager of the Gibson company's Indianapolis branch.

F. E. A. Brock, St. Louis, Secretary of the Vesper-Buick Auto Co., has resigned that position to enter the candy trade in this city. He will be succeeded by E. R. Stewart, salesmanager, who will become assistant manager. Oscar Norris of the Maxwell Branch, Kansas City, succeeds Mr. Stewart. Mr. Brock had been with the Vesper-Buick Co., since Mr. Vesper came here as Buick distributor.

C. F. Barth has been made works manager of the C. R. Wilson Body Co., Detroit. During the past three years he has been factory and production manager of the Murphy Chair Co., Detroit.

G. D. Wilson has been made manager of production and sales of the C. R. Wilson Body Co. and will also have charge of the inspection department. For the past four years he has been production manager.

T. J. Turk, chief engineer of the Interstate Motor Co., Muncie, Ind., has been appointed assistant general manager of the company. He will also retain charge of the engineering department.

W. I. Ballentine, Indianapolis, Ind., formerly general superintendent of the Link Belt Co.'s Indianapolis works, has resigned to accept the position of works manager of the Chain Belt Co., Milwaukee.

Dealer

J. Edward Jones and V. R. Washburn, who have been connected with the sales department of the Ohio Auto Sales Co., Columbus, have formed a sales firm known as the Jones-Washburn Motor Co., to be located in Piqua, Ohio, to handle Dodge.

Lichtlie Automobile Co., Toledo Ohio, will open a branch in Lima at once. G. H. Hack will be manager. It will handle the Chandler and National.

Hudson-Phillips Motor Car Co., St. Louis, has opened a special truck department at their salesrooms, 3301 Locust Street, for Diamond T and Vim trucks.

Henry Hotze & Son, St. Louis, has taken the agency for The Pilot cars. George A. Frey is manager of the salesrooms opened at 2809 Locust St.

Federal Truck Co., St. Louis, has been selected as distributor for Troy trailers.

Henderson-Overland Co., Youngstown, Ohio, with a capital stock of $100,000, has been formed to take over the sale of Overland cars in North Eastern Ohio and Western Pennsylvania which was formerly conducted by James A. Henderson.

Chamberlain Automobile Co., agent for the Apperson and Velie cars at New Bedford and Fall River, Mass., has bought the S. Leyden garage at Fall River and placed W. T. Sandeman of Boston in charge of the agencies there.

Louis Jandorf is going out of the automobile body selling field. A sale was held Oct. 17 at the New York building.

Times Square Auto Supply Co., New York City, has opened a branch at 880 Nassau Street.

Bearing Service Co., Detroit, is establishing a branch in Kansas City, at 2205 Grand Avenue, and will open about Nov. 1.

Chevrolet Motor Co., Kansas City, Mo., will establish a wholesale and parts department in the Firestone building, retaining the present quarters at 1610 Grand Avenue for retail and service department.

Chalmers Motor Sales Co., Kansas City, Mo., will soon move from 1506-08 McGee Street to 2615-17 Walnut Street, where it will occupy the basement and first floor of the recently completed Shukert building.

O. E. Morehouse and S. C. White, Kansas City, Mo., formerly successful grocers, have formed the Pullman Motor Sales Co., to retail and distribute Pullmans in this territory. G. W. Compton, division sales manager of the Pullman company, will handle the distribution department.

Columbia Tire & Rubber Co., Seattle, Wash., has opened quarters at 905 East Pike Street, from which station Columbia tires will be distributed to Western Washington points.

Reinhard Bros. Co., Minneapolis, dealers in accessories, will have a new four-story building on Ninth Street near Hennepin Avenue. The building will be ready Feb. 1 and will cost $75,000.

Welling Motor Equipment Co., St. Louis, has been organized by Conrad A. Welling of the Monarch Auto Repair Co., to handle the Ford starter made by the Detroit Starter Co., and the Compensating Vapor Plug. The salesroom will be at 613 Chestnut Street.

Moreland Motor Truck Co., Los Angeles, will shortly begin the construction of an assembly plant in Seattle, which will be the Northwest distribution point for their product.

E. A. Allen is the manager of a new tire store in Seattle at Broadway and Pine Street, and will handle the Lancaster Wiregrip tires.

W. D. Sharp Co. has been organized in Seattle to handle the Cole line, and salesrooms and service station have been opened at Tenth Avenue and Seneca Street.

O. E. Logan of the Chalmers Auto Co., Spokane, Inland Empire distributor for the Chalmers, closed with C. F. Kolle of Kalispell, Mont., to handle the Chalmers. T. C. Martin has contracted to handle the Chalmers line at Pullman, Wash.

W. W. Trumbull, manager of the Spokane Auto Co., has contracted to distribute Oakland cars to all points in Washington east of the Cascades and in Idaho north of Salmon River.

Fowler Motor Car Co. has taken on the KisselKar line for Springfield, Mass., and vicinity.

New England Velie Co. is now located in its new building, 1123 Commonwealth Avenue, Boston, where it has executive, sales and service departments all in one structure.

Chalmers Motor Co. of New England moved into a new building at Portland, Me.

New York Lubricating Oil Co., Denver, is the new name for the Monogram distributing agency for Colorado, Wyoming and New Mexico, at 1441 Wazee Street, formerly called the Dickey Oil Co. G. B. Hayward, a salesman for the former concern, is manager of the new Western branch, and W. G. Dickey, head of the former Denver agency, has gone to Kansas City to manage the branch there under the name of the New York Lubricating Oil Co.

Tom Botterill, Denver, Pierce and Hudson distributer for Colorado, Wyoming and New Mexico, and Dodge dealer for Denver and vicinity, with headquarters at East Thirteenth Avenue, Broadway to Lincoln Street, has secured the Colorado, Wyoming and New Mexico distributing agency for the Pierce truck.

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, NOVEMBER 2, 1916—CHICAGO No. 18

A. O. Smith Corp. Formed

Stock on Curb—Offers $3,000,000 Preferred and 100,000 Shares Common

NEW YORK CITY, Nov. 1—One more company has entered Wall Street activities by listing its stock on the Curb. Increased business, as in the majority of cases, has been the cause of the formation of a new company to accommodate further factory expansion. The A. O. Smith Corp. has just been formed to take over the entire plant, assets, business and good will of the A. O. Smith Co., Milwaukee, manufacturing pressed steel frames, pressed steel rear axle housings, heavy stampings and drop forgings. An offering of $3,000,000 7 per cent cumulative preferred and 100,000 shares of common is being made in Wall Street. W. P. Bonbright & Co., and White, Weld & Co., this city, and Elston & Co., Chicago, have purchased the entire issue of preferred and are offering it at 98 with the privilege of subscribing to 40 per cent in common at $35 a share.

Management Unchanged

The management of the company will remain unchanged under Raymond Smith, who is president and general manager and chief stockholder.

The old company has been in active operation since 1904, having succeeded to the business of the Federal Mfg. Co. Average net earnings of the company after full depreciation for the 5 years ended July 31, 1916, were $474,540; for the year ended July 31, 1916, $1,505,162, or more than seven times the new preferred dividend requirement of $210,000. Net earnings for the year to end July 31, 1917, are estimated at $1,800,000. Net assets of the new corporation will be in excess of 113 per cent and net quick assets in excess of 45 per cent of the preferred stock. The stock has a sinking fund of at least 20 per cent of net earnings after preferred dividends, commencing Oct. 1, 1917, which is to be applied to purchase and cancellation of the stock. No dividend in excess of $6 per share per annum can be paid on the common stock until the amount of the preferred has been reduced to $1,500,000.

—

Chalmers Refinancing Under Way

NEW YORK CITY, Oct. 28—Plans for the refinancing of the Chalmers Motor Co., Detroit, are now being worked out by J. S. Bache & Co. and C. D. Barney & Co., both of this city. Though the details of the transaction have not been consummated, it is stated that the company will acquire an addition of more than $5,000,000 in working capital. It is expected that the plan will be announced in the near future.

—

Smalley Is Bound Brook Bearing V.-P.

BOUND BROOK, N. J., Oct. 30—George O. Smalley has been promoted to first vice-president and general manager of the Bound Brook Oil-less Bearing Co., succeeding the late Leigh S. Bache. Mr. Smalley has been connected with this company for 10 years and for the last 4 years as assistant general manager and assistant treasurer.

—

Railroad Car Shortage Grows

DETROIT, MICH., Oct. 30—The freight car shortage is now greater than was ever before experienced at this season of the year. On Sept. 30 there was a net shortage of 61,030 cars as compared with a surplus of 131,027 cars on Oct. 1, 1914 and of 78,299 on Oct. 1, 1915.

—

Disco Reduces Ford System $10

DETROIT, MICH., Oct. 28—The Disco Electric Starter Corp., this city, has reduced the price of its electric starting and lighting systems for Ford cars $10 to $65.

United Motors Adds Radiator Co.

Addition of Harrison Mfg. Co. Makes a Total of Eight Units

NEW YORK CITY, Oct. 31—The Harrison Mfg. Co., Lockport, N. Y., has been purchased by the United Motors Corp. The Harrison company manufactures radiators. The same policy will be followed with regard to the Harrison company as with the other concerns which the United Motors Corp. has taken over. The purchase of the Harrison company brings the total United Motors Corp. purchases up to eight companies, these being: Hyatt, New Departure, Delco, Remy, Perlman, Klaxon, Brown-Lipe-Chapin and Harrison.

The Harrison Mfg. Co. now becomes the Harrison Radiator Corp., and plans have been perfected to increase its present capacity of 350 radiators daily to 3000 per day. The corporation will make radiators for Chevrolet and other General Motors Co. subsidiaries.

The directors of the Harrison company have voted to keep the industry in Lockport and have secured options on all property adjacent to the plant on which a three-story factory will be built at once to cost $300,000. Further additions will follow. The company will employ about 700 men when the new facilities are available. It now has nearly 300 on its payroll. The enlarged factory capacity will be ready by March, 1917.

—

Michigan Wheel Co. to Make Joints

GRAND RAPIDS, MICH., Oct. 25—The Michigan Wheel Co. is floating an issue of $50,000 preferred stock in the company for the manufacture of an automobile joint about to be marketed. With the completion of the subscription joint manufacture will start immediately.

Emerson Buys Plant at Kingston

Materials, Engines and Parts Purchased for First Lot of 500 Cars

NEW YORK CITY, Oct. 30—The Emerson Motors Co. of this city, manufacturer of the Emerson four-cylinder car, deliveries of which are soon to start, has purchased a factory in Kingston, N. Y., where the car will be produced in quantities. The factory purchased last week is known as the Peckham plant. The deal for it was made with Almirall & Co. of this city. This factory when equipped will have capacity for 100 cars per day. There is a machine shop 424 by 70 ft., which is having an addition of 96 by 70 ft. built which is incorporated in the 424 by 70 dimensions. There is a main factory 487 by 224 ft., with a 2-in. plank floor, which will be used for assembly purposes; and in addition are four warehouses with floor area of 70,000 sq. ft. The power house is 60 by 40 and the office building 50 ft. square. At present there is no machinery in the plant. As soon as the floors are finished machinery will be installed, and T. A. Campbell, president of the company, says that much machinery has been purchased and will be installed as soon as the floors are ready.

In addition to this new plant the company has a factory in Long Island City of 18,000 sq. ft., where the first 110 cars will be built.

The Emerson company early in October placed its contract for the manufacture of 500 motors with an outside concern. These motors are to be all delivered by contract before Jan. 8. Deliveries on these motors will be starting in the near future. The company has already built ten cars, which have been running for test purposes.

That the Emerson company is prepared to go forward with its first lot of 500 is proven by the orders placed for other car components and the quantity of these at present on hand. Over 100 frames are already on hand and the other 400 on the way to the factory. The 500 bodies are at present well under way and will all be delivered by Dec. 20. Ninety axles are on hand and two carloads are in transit. All of the 500 will be delivered by Dec. 21. There are 100 gearsets and 300 sets of lamps on hand. Starters are to be coming through at fifty a week. There are 200 sets of springs on hand. The same stock of parts applies to many other minor components of the car.

To date the Emerson company has not signed with a single agent or allotted agents territory. No money has been accepted from agents as deposits for cars for agency rights. There are applications on hand from several thousand agents for territory, and allotment of territory will be started on Dec. 15.

There have been sold to date over 200 cars by direct sales to consumers. These have been sold at retail price with a cash deposit of 10 per cent. No specific delivery date has been given, but delivery will be by rotation in order of deposits. The cash deposited on these cars is held as a separate account and is deposited in one of the trust companies in Long Island City.

The finances of the company as of Oct. 1 are shown by the audit report of the American Audit Co. of this city, which shows liquid assets at that date of approximately $551,000. Cash on hand totaled $307,447 and securities $182,000.

Studebaker to Raise Prices Dec. 1

DETROIT, MICH., Oct. 28—The Studebaker Corp. will shortly announce an increase in the prices of its various models, to take effect on or about Dec. 1. The increase will be between $75 and $100 on each of its products.

Cole Prices to Advance Jan. 1.

INDIANAPOLIS, IND., Oct. 30—The Cole Motor Car Co., this city, will increase the price of its cars on Jan. 1, 1917, by $100 to $200. The present price of the Cole eight is $1,595.

Canadian Ford to Make Trucks

DETROIT, MICH., Oct. 28—The Ford Motor Co. of Canada, Ltd., will begin the manufacture of trucks in March, 1917.

Berger and Thompson with Abbott

DETROIT, MICH., Oct. 25—Fred Berger has been appointed chief of the engineering department, and Alfred Thompson, factory and production manager of the Abbott Corp.

Schulz Is Mercer Chief Engineer

TRENTON, N. J., Oct. 29—A. C. Schulz has been appointed chief engineer of the Mercer Automobile Co., this city. Mr. Schulz was formerly connected with the Locomobile Co. of America in the capacity of assistant chief engineer. He was with Locomobile for 14 years.

Alford Vice-President of Nash

KENOSHA, WIS., Oct. 28—W. H. Alford, formerly Comptroller of the General Motors Co., has rejoined his old chief, C. W. Nash, as vice-president and comptroller of the Nash Motors Co.

White Empire Purchasing Agent

INDIANAPOLIS, IND., Oct. 30—E. E. White has been appointed purchasing agent of the Empire Automobile Co., this city. Mr. White has been associated with the Premier and American companies in this city.

Monroe Co. Increases Capital

Raises Stock from $250,000 to $1,000,000—R. F. Monroe Elected President

DETROIT, Oct. 27—The Monroe Motor Car Co., Pontiac, Mich., has increased its capital from $250,000 to $1,000,000. New officers were elected at a directors' meeting held Oct. 24, and include R. F. Monroe, president and general manager; S. W. McFarland, secretary and treasurer, and S. S. Jenks, vice-president and manufacturing manager. The board of directors is composed of R. F. Monroe, S. W. McFarland, S. S. Jenks and W. C. Rowles, Pontiac; L. E. Haase, general sales manager, and R. T. Armstrong of the Armstrong Mfg. Co., Flint, Mich. S. W. McFarland was formerly the secretary and treasurer and S. S. Jenks was the manager of the Port Huron Construction Co., Port Huron, Mich., which has now been purchased and absorbed by the Monroe Motor Car Co. Mr. McFarland is also cashier of the Port Huron Commercial Bank.

The company plans to utilize the Port Huron plant for the construction of motors until some time in the future, when the plant will be moved to Pontiac.

The Monroe company, which opened its plant in August, 1914, making its first delivery Jan. 1, 1915, has heretofore been selling its product through the Chevrolet company of Flint. It will sell its cars directly in the future. The company made 3500 small roadsters in the past year and plans to turn out approximately 7000 cars during the coming 12 months, which will include 2000 small roadsters with roadster, clover-leaf or sedan bodies and 5000 four-cylinder touring cars with either touring or clover-leaf bodies. Its prices will be $565 for its present roadsters, $635 for the clover-leaf roadsters, $965 for the sedan and $985 for the new touring cars with either touring or clover-leaf bodies.

Murphy Joins Hoyt Service

CLEVELAND, OHIO, Oct. 30—Gail Murphy has become manager of the local office of the Hoyt's Service, New York, advertising and sales management. For the past year Mr. Murphy has been advertising manager of the Chalmers Motor Co., Detroit. His headquarters are in the Leader-News Building.

Lane Is U. S. L. Vice-President

NIAGARA FALLS, N. Y., Oct. 28—At the recent meeting of the board of directors of the U. S. Light & Heat Corp., C. L. Lane, who has been secretary of the company, was elected vice-president.

Oct. Shipments 19,510 Carloads

Freight Car Shortage Hampers Manufacturers—License Case Argued in Washington

CARLOAD SHIPMENTS OF AUTOMOBILES

Month	1916	1915
January	18,064	8,369
February	21,502	11,273
March	28,600	16,442
April	28,000	17,112
May	24,000	13,642
June	23,879	15,325
July	18,079	12,517
August	18,254	16,959
September	21,660	18,940
October	19,510	17,848

NEW YORK CITY, Nov. 1—According to statistics submitted by the traffic department of the National Automobile Chamber of Commerce at the directors' meeting to-day there were 19,510 carloads of automobiles shipped during the month of October, with 1 day missing, as against 17,848 carloads for the same month last year. Shortage of freight cars continues in all lines of trade.

The commercial vehicle department reported that it was endeavoring to supply complete data to the lawmakers in various States in connection with proposed legislation governing the use of trucks on the highways, which will permit the special commissions and others to make recommendations for reasonable legislation which will not hamper the growth of the commercial vehicle industry.

Charles Clifton, president of the N. A. C. C., will act as national councillor representing the automobile manufacturers' organization in the Chamber of Commerce of the United States.

At Washington on Wednesday counsel for the N. A. C. C. argued the automobile license case before the Supreme court having to do with the constitutionality of the State registration law. The case is to decide whether the States have a right to raise funds for good roads work under the guise of registration fees and whether they can interfere with interstate traffic and require registration of a motor vehicle which has already complied with the registration laws of its home State.

In attendance at the meeting were: Charles Clifton, president, Pierce-Arrow; C. C. Hanch, Studebaker; Hugh Chalmers, Chalmers; R. D. Chapin, Hudson; William E. Metzger, Columbia; H. H. Rice, Waverley; Carl H. Pelton, Maxwell; Windsor T. White, White; A. L. Riker. Locomobile; R. E. Olds, Reo; John N. Willys, Willys-Overland; Alfred Reeves, general manager, and S. A. Miles.

48,750 Studebakers Built by Canadian Company

WALKERVILLE, ONT., Oct. 28—For the first 8 months in 1916, sales of Studebaker cars exceeded the record for the entire year of 1915, according to figures just announced by J. E. Grady, sales manager of the Studebaker Corp. of Canada, Ltd., Walkerville.

In number, the cars, 48,750 Studebakers were sold from Jan. 1 to Aug. 31 of this year, as compared with 47,040 for the whole of last year, a gain of 1710.

At the present rate 1916 sales will be 55.4 per cent greater than in 1915, or 73,125 cars this year compared with 47,040 last year, a gain of 26,085. As a matter of fact, however, the balance in favor of 1916 over 1915 will be greater than the estimate just given, for the Studebaker output is being steadily increased and the sales for the last 4 months of this year promise to be larger in proportion than for the first 8 months of the year.

Sept. Exports Lower Than in 1915

Though Number of Cars and Trucks Falls Off, Value Is Slightly Higher

WASHINGTON, D. C., Oct. 30—There was a pronounced falling off in the exports of automobiles in September last as compared with the same month of last year, according to the returns of the Department of Commerce, announced to-day. The exports in September last were as follows: Commercial cars, 1835, valued at $5,203,215; passenger cars, 3585, valued at $2,819,405. For the same month of last year the exports were: commercial cars, 2227, valued at $5,882,255; passenger cars, 4299, valued at $3,215,459. The gain during the month was in the exports of parts, not including engines and tires, which rose in value from $1,613,419, in September a year ago to $2,095,188, in September last.

Detailed statistics for the various countries appear in the table.

Fewer Trucks Shipped

Taking the figures for the 9 months' period, ended September, there is a distinct loss in the exports of commercial cars, for this year's period, due to the curtailment of war orders, while passenger car exports show a tremendous gain. The figures show that during the 9 months ended September, 1915, there were 17,269 commercial cars, valued at $47,769,216, shipped abroad, as against 14,773 cars, valued at $40,371,055, exported during the same period of this year. Passenger car exports during the 1915 period amounted to 31,036 cars, valued at $26,793,972, while during the

Marmon Co. Rushes Additions

Assembly Plant To Be Further Enlarged — Improved Power Facilities

INDIANAPOLIS, IND., Oct. 30—The Nordyke & Marmon Co. is steadily adding buildings and making improvements to its plant in order to take care of the increasing demand for the Marmon 34. Last winter the company felt the pinch of room and erected a large final assembly building 100 by 400 ft. on a plot of ground across the street from the main plant. Building operations are being rapidly pushed at the present time to add some 500 ft. to this building so that when it is completed it will be a structure almost 900 ft. long by 100 ft. wide. In addition a large capacity heating and power plant will also be erected.

Considerable improvements are also being made on the original factory plot by an additional two new buildings center of the plant including a new blacksmith's shop with several thousand feet of floorspace and a new experimental building which will contain about 4000 ft. of floor space.

New loading and unloading docks with additional railroad siding facilities are also being completed and additional shipping docks for wagon freight have been erected.

An interesting feature of these changes is the passing of the old brick stable for horses which has been a part of Nordyke & Marmon Co.'s plant for almost 2 decades. Automobile and motor trucks have almost wholly taken the place for hauling and the stable of olden days has been converted into a new employment office and factory doctor's headquarters.

—

Dodge to Build Additional Factory

DETROIT, MICH., Oct. 28—Permit has been given to Dodge Bros. for erection of an additional factory to cost $300,000. The building will be used as a warehouse and will be 310 by 118 ft.

—

Alvin Heads Schoeneck Co.

CHICAGO, ILL., Oct. 30—F. J. Alvin has become president and general manager of the Schoeneck Co., this city and Harvey, Ill., maker of the Geneva six. This company was recently formed with a capital of $1,500,000 to build the car designed by George Schoeneck, well known in the automobile field and connected with such concerns as Renault and Palmer & Singer.

Mr. Alvin was at one time connected with the American Ever-Ready Co. He then formed the National Sales Corp. in this city, which controlled the entire factory output and sales of the Schebler carbureter, Dow magnet, Kingston coils, etc. Later he took entire charge of the business of the Byrne-Kingston Co., Kokomo, Ind., in Detroit, and later became sales manager of the Sears-Cross Co. In 1915 he formed the New Era Engineering Co. to manufacture the New Era car at Joliet.

—

Pontiac Plant for Olympian Motors

PONTIAC, MICH., Oct. 30—The Olympian Motors Co. will permanently locate its plant in this city. The company is incorporated under the laws of Delaware for $1,000,000, all of the stock being common with a par value of $100 per share. The company takes over the business of the Pontiac Chassis Co., which has been manufacturing chassis for the market in large quantities for some time. From 12,000 to 15,000 cars will be built annually.

—

Empire Axle Plans Large 1917 Production

DUNKIRK, N. Y., Oct. 30—That the automobile and truck axle manufacturing companies are sharing in the general prosperity of the country is manifested in a statement made by the Empire Axle Co. that it will put out as many axles in the first 4 months of the coming year as it did in the whole year of 1916. It has increased its daily capacity in worm drive axles more than 400 per cent over that of a year ago.

Increased demand and production necessitated an increase during the year of 54,600 sq. ft. in its factory space, centered mainly on three new buildings, 85 by 110; 30 by 50; and 85 by 100. The first building is being used as an assembly plant, tool making and some machine work; the second is an addition to the assembly plant, used as a forge shop; the third is not yet built, but will be used for the machining of castings, etc. Preparations are also being made for an office building separate from the factories.

Keeping in line with the general improvement in working conditions in the modern factory, the company has made several important installations to its plant. Scientific sanitary facilities for its employees in the way of steel lockers, shower baths, and special lavatories have been added; also bulletin boards displaying new safety-first ideas, safety appliances and guards on all machinery and many other improvements.

The gradual increase in its business has made necessary two shifts throughout the plant. The heat treating department has been operating night and day for the last 6 months. The power plant has not been idle for more than 1 hr. at a time with the exception of holidays, since May, 1915.

Franklin To Increase Production

Company Has Added Six New Buildings This Year at a Cost of $1,000,000

SYRACUSE, N. Y., Oct. 25—Factory expansion this year by the H. H. Franklin Mfg. Co., this city, has been centered in six new buildings, giving an additional factory space of approximately 550,000 sq. ft. at a total cost of over $1,000,000. These increased manufacturing facilities are at present enabling the company to produce twenty-seven cars per day, as compared with eleven per day a year ago. Within the next 6 months the company will produce forty cars per day. Between Oct. 30, 1915, and Oct. 2, 1916, the production force has changed from 1215 to 2133.

The development that has taken place in the enlargement of factory space this year has been in a one-story building, 154 by 160, costing $40,000, used for the experimental department, chassis testing and the sawmill; a three-story building, 60 by 100, costing $30,000, for die casting; a six-story building, 108 by 265, costing $250,000, for manufacturing; an employment office and hospital, costing $4,000; a building for lumber drying, costing $6,000, and a six-story, 240 by 300 structure now being built at a cost of $500,000 for shipping and manufacturing.

Better Factory Methods

Improvements have taken place in the methods of manufacture and in the handling of the employees. Among its major improvements in manufacturing methods are the complete development of humidified oven drying apparatus for the paint department, completely eliminating the use of the old style of brush in the paint shop except in the last coat of varnish; pneumatic methods of drilling cap screw and nut driving, as well as wood screw driving. To thoroughly provide safety for its employees a safety man, who was formerly in charge of the first-aid room, is taking care of the safety devices. During the year the company has designed and put into use an entirely new set of manufacturing tools, costing approximately $300,000.

Workmen Rated

Probably not the least important in the changes during the year is the new method of rating workmen and supervisors, up to and including the foremen, which has resulted so far in the increase in wages of 5½ cents average per man since April, 1916, applying to approximately 25 per cent of the entire working force of the factory.

Surplus of 2-In. Maple

Uncertainty of Steel Deliveries May Affect Sales to Body Builders

ST. LOUIS, MO., Oct. 30—For the first time in 5 months there is a surplus of 2-in. maple offered in the hardwood market here. Maple of 2 in. and thicker is used almost exclusively by automobile builders for frames on which to build the metal sides of the bodies. The maple is to-day quoted at $27 per 1000 ft. at the mill, or at about $35 at most of the automobile factories. There is considerable speculation here among hardwood men as to why this accumulation while the automobile industry is forging ahead so rapidly. There are two explanations: First, the automobile builders are not buying far ahead because they are uncertain as to the steel deliveries; second, the rapid advance of maple last spring and a scarcity for a time persuaded the mills to cut more than is needed. The figures in the hands of the local sawmill men do not bear out the latter theory.

St. Louis a Center

A very large proportion of the maple used by the automobile industry is sold in this city, which is one of the great hardwood markets of the country. It is the largest hardwood reshipping point, there being half a dozen large reshipping yards here and a dozen small ones. These yards buy hardwoods from small yards throughout this section and the South, and regrade the lumber here and then reship it. Most of the maple produced in this country comes from Missouri and Arkansas, and the Missouri cut is estimated at 4,000,000 ft. The Arkansas cut is smaller. Maple is only an incidental part of the output of mills, probably the largest output being that of the Gideon-Anderson mill at Gideon, Mo., with sales offices here. The output of this mill is about 750,000 ft. a year, while the mill cuts more than 100,000 ft. daily of all hardwoods. From 250 to 500 ft. of lumber is required for an automobile.

Before the automobile industry came into being, maple was used chiefly by furniture makers and was then not cut more than 1½ in. thick and sold on a mill basis of about $15 per 1000 ft. At first ash was used for automobile body frames, but when it mounted to $50 per 1000 ft. a substitute was sought and was found in maple. In the 4 years since this use of maple began the price has advanced about $9 per 1000 ft.

Gum Widely Used

Last spring there was a pronounced scarcity of maple and for a short time there was considerable bidding for it; but the builders of lower-priced machines turned to gum and relieved the pressure. Some of the gum used for automobiles is sold through this city, but a greater portion is sold through Memphis. One-inch gum has for a long time been used by automobile builders for floors, etc. Yellow pine, which is sold chiefly through this city and Kansas City, is used for crating.

Wagon Makers to Merge and Build Motor Vehicles

CINCINNATI, OHIO, Oct. 30—Steps have been taken by almost a score of wagon manufacturers of this city for the merging of their interests into a large concern for the manufacture of both horse-drawn and motor-driven wagons, to be used for all purposes. A preliminary meeting was held Oct. 28, when the project was discussed and Attorney Emil Hauch was instructed to draw up the articles of incorporation for a $500,000 concern.

It is planned to erect a large central plant and use a number of the existing plants as branches. Some of the present plants will be abandoned entirely. Among those interested in the movement are Fred Dhonau, Jr., president of the F. Dhonau Son's Co.; L. J. Froelicher of A. Froelicher Sons Co., Michael Klopp of Philip Klopp & Sons, George Finn of the J. Finn Sons Co., J. H. Lewis, H. Burdorf and Harry W. Monning, individual manufacturers.

Goodyear Secures Cotton Plantation

PHOENIX, ARIZ., Nov. 1—In order to obtain a fixed supply of long staple Egyptian cotton, the Goodyear Tire & Rubber Co., Akron, Ohio, has purchased 10,000 acres of land in the Salt River valley, and will at once embark in the business of cotton raising on a large scale.

It is reported that the Goodyear company is also planning to increase this acreage by leasing from 20,000 to 25,000 acres additional, leases to run for 5 years. Contracts to supply the Goodyear company with long staple cotton have been awarded the operating corporation, on long-term contracts.

American Chain Co. Buys Standard

BRIDGEPORT, CONN., Oct. 28—The American Chain Co., manufacturer of Weed tire chains in this city, has purchased the Standard Chain Co., Pittsburgh, Pa. Announcement of the acquisition of the Standard company was made at a dinner given to the distributors of Weed chains by the American Chain Co.

Plans for combining the sales organizations and part of the office force of the two companies are in preparation and will probably be put into effect by Jan. 1.

Welfare Work at Remy Plant

Special Bldg. for Women Employees—Co-operates in Teaching Electricity

ANDERSON, IND., Oct. 30—The extensive construction work that is under way at the plant of the Remy Electric Co., Anderson, is not concerned entirely with increasing the production of the various units. A part of the building activity is directed at co-operative welfare work with the employees.

Ground has just been broken by the company for a two-story building designed solely for the many women employees. The new building will be devoted to the manufacture of small parts of its products at the making of which women are particularly adept. The structure will contain every convenience for the transfer of work so no lifting need be done, the interiors will be painted white and there will be rest rooms.

The Remy company is working in cooperation with a local high school in the teaching of the elements of electricity. The school has a membership of 400, meets 3 nights a week and gives Remy employees, young men and women in the local high school and anyone else interested the opportunity of securing a practical training in electricity. The Remy company furnishes text-books at cost and pays the salary of the instructor.

Pa. Rubber Establishes Sales Districts

JEANNETTE, PA., Oct. 31—The Pennsylvania Rubber Co., this city, will establish districts under sales directors in order to give closer attention to the various sections of the country. This does not mean that the whole branch system has been abolished, but merely that the branches will now come under certain districts and sales directors as follows: Eastern territory, C. C. McCullough; southern district, D. D. F. Yard; central States, J. Q. Goudie; the west, C. F. Kent; and the Pacific Coast, J. F. Madden. Vice-President C. M. DuPuy will continue in charge of the Pennsylvania district.

Holt-Welles Co. Elects Officers

NEW YORK CITY, Oct. 28—At the recent annual meeting of the stockholders of the Holt-Welles Co., Inc., New York, manufacturer of the Branford and Browne carbureters, the following officers were elected for the ensuing year: E. H. Stickels, president; F. E. Hamilton, vice-president and counsel; Calvert Holt, treasurer; Paul Welles, secretary; Wm. M. Williams, assistant treasurer and secretary.

U. S. A. Cars Gain in Chile

Value of Shipments Jumps from $44,169 to $202,498 in Year

SANTIAGO, CHILE, Oct. 18—That the American automobile industry is fast getting a foothold in Chile is manifested in the fact that U. S. A. shipments to that country increased from $44,169 to $202,498 from 1913 to 1915. Though there was a slight decline in automobile imports as a whole during 1915, and Chile's purchases of foreign automobiles declined considerably, the American car's popularity held strong with much larger sales.

That the automobile is popular in Chile is proved in a comparison of its imports from 1908, 1909 and 1910, which were $14,054, $11,760 and $26,971, respectively. At present there are about 1300 cars in this city, between 300 and 400 of them being used as taxicabs at a charge of $1.10 in U. S. gold, or about 22 cents a trip.

Poor road conditions will not allow of many trips outside of this city, and as a result the most popular cars for private use are broughams, limousines, and landaulets. Black and dark blue cars should be sent only on special order. The prospect of better roads is not particularly encouraging, although there is some talk of building one between Santiago and Valparaiso. In such a case there should be an increased demand for touring cars.

Two-seated runabouts are not common, and when seen generally have a small seat behind for the chauffeur. This is demanded by custom, for even though the owner of the car is driving he must always have the chaufleur with him in case of need. American runabouts with a third seat behind, which could be folded into the body when not in use, thus giving the car a smarter appearance, should find a market.

Trucks are not used to any extent in the central and southern part of the country and the low cost of hauling by oxcart and wagon would limit their introduction. In the nitrate fields, however, they have begun to be used with good results.

The maximum price for gasoline during the past few months was $5.45 per case of two 5-gal. tins, which is the method of handling used here.

—

New Zealand a Fertile Field for Automobile Sales

AUCKLAND, NEW ZEALAND, Oct. 20—If we judge a country from its export trade then New Zealand must be put in the prosperity column, for its exports have increased 30 per cent in the last year. These islands are the most fertile areas in the world and naturally good automobile markets. The European war, and increased demand for foreign products, account for the present prosperity.

U. S. Leads in Imports

As a consumer of automobiles, motorcycles, etc., New Zealand imported in 1915, $6,889,893. The United States lead all of the countries in supplying this demand. The value of cars imported from the U. S. A. was $1,842,948, whereas the value supplied by the United Kingdom was $1,612,671.

An indication of how New Zealand profited by the war is that wool, which is the greatest product, increased 22½ per cent in value; frozen meats, which constitute the second greatest article of export, increased 30 per cent; butter in fourth position as an export, rose 20 per cent; cheese rose 30 per cent in value: and other export articles increased similarly.

—

Perlman Stock on Exchange Basis

NEW YORK CITY, Oct. 30—L. G. Kaufman and W. C. Durant have caused to be sent to the Perlman Rim Corp. stockholders notice that on presentation of their Guaranty Trust Co. receipts, United Motors Corp. stock will be issued forthwith. It was agreed that this release would be made on Nov. 25, but it is decided to grant the release at once.

Metal Prices Are Higher

Rise in All Steel Quotations Also Extends to Rubber and Other Materials

NEW YORK CITY, Oct. 31—Metal prices featured last week's market activities with a general rise in all departments. Bessemer and open-hearth steel reached $50.00 per ton at a gain of $5.00; beams and channels rose 9 cents per 100 lb. to $2.97; and tin rose 75 cents per 100 lb. to $42.00. Rubber prices have also followed suit with the metals with a large rise. Fine up-river Para is now quoting at 81½ cents a pound, just 6½ cents higher than a week ago; Ceylon is 2½ cents higher a pound at 63½. Rubber from the Dutch East Indies is now in the midst of a boom and its production there is increasing by leaps and bounds. According to authoritative statements, the crop harvested last year in the island of Java alone was 6,059,098 kilograms, as against 3,260,274 in 1914, and it is estimated at as much as 9,205,825 kilograms in the current year.

Drought in Brazil

In regard to the rise in Para rubber, it may be explained as due to a drought in the Amazon region of Brazil. The water is so low in the tributaries of the Amazon that many steamers are lying at Para and Manaos, loaded with provisions for the rubber country, but unable to get there. By the same token, the rubber-laden up-river ships cannot get down.

Fuel prices remained constant last week. Gasoline prices in some sections of the country have gone down with no prospects of a sustained decline. Crude oil prices are still quoting at their record quotations. The high prices of crude oil have indirectly brought the price of gasoline down, at any rate, have eased the tension on quotations. Before crude prices rose, it was stated that refiners found it impossible to get the required quantity of different grades.

Parts Companies Add Capital

CONNERSVILLE, IND., Oct. 30—The Metal Auto Parts Co. has increased its capital from $50,000 to $150,000.

—

PERU, IND., Oct. 30—The Peru Auto Parts Mfg. Co. has increased capitalization from $200,000 to $500,000.

—

Punctureless Tire to Increase Capital

AKRON, OHIO, Oct. 25—In order to take care of factory expansion the Punctureless Auto Tire Co., this city, has called a meeting of the stockholders

for Dec. 25 to vote on an increase in capitalization from $100,000 to $1,000,000. An additional five-story building will be erected. A plant is now being operated at Kenmore. Twenty-five men are employed and the working force will be increased to 100 within a month. The company is also operating a plant at Millersburg. Within 6 months the company will be turning out 500 tires daily, according to present plans and in consideration of the increased factory facilities which will be available.

Auto Wheel Increases Capital $200,000

DETROIT, MICH., Oct. 28—The Auto Wheel Co., Lansing, Mich., has increased its common stock capitalization from $300,000 to $500,000. The issue was authorized by the directors at the annual meeting of the board on Oct. 24. The funds derived from the increase will be devoted to new buildings to care for increased business. Officers of the company remain the same and include E. S. Porter, president; H. E. Bradner, vice-president; D. L. Porter, secretary and treasurer, and John Winters, superintendent.

—

Billings & Spencer to Expand

HARTFORD, CONN., Oct. 28—Shareholders of the Billings & Spencer Co. have authorized the issue of 10,000 shares of stock and holders of record last Saturday have the privilege of subscribing for 10,000 shares of unissued stock at par, $25 per share, on or before Nov. 18 at the rate of one new share for every two shares now held.

Slump in Security Prices

—

Bearish Market Results in Drops of from a Fraction to 30 Points

NEW YORK CITY, Oct. 31—Automobile and accessory issues last week were in the hands of the bears who are at last realizing much profit on a down market. Chevrolet, General Motors and United Motors were especially low as a result of much selling pressure. Chevrolet dropped 11 points during the week, reaching 186; General Motors dropped to 800, a loss of 30 points; and United Motors to 62½, a loss of 4⅛ points. The latter stock has been very active on both sales and buys. The automobile securities have been a big puzzle to investors and speculators during the last month on account of their failure to make any material gains. When news of the submarine activities was flashed on the ticker recently the stocks held strong with few losses. Now with no apparent cause they are quoting low.

Some Liquidation

Of course liquidation of stock has lowered prices to some extent, as in Lee Rubber. This stock reached 39, the lowest price at which the stock has ever sold, notwithstanding the earning of its present $3 dividend in the first 6 months of the year. Maxwell has fluctuated during the past 2 weeks, recording fractional gains last week and dropping badly this week. Willys-Overland common, after recording a fractional gain the previous week, dropped 3⅜ points.

Several of the issues, however, showed considerable strength as a result of important announcements. Chalmers common and preferred rose 15 and 8 points, respectively. This company, it is stated, is considering a plan for fresh financing in which an addition of more than $5,000,000 working capital will be used for expansion.

Spicer Strong

Spicer preferred, a new stock on the Curb, picked up 2¼ points. All the $1,500,000 first preferred 8 per cent cumulative and convertible stock of this company has been sold.
